Lewers[1] has made a careful study into the relative advantages of vaginal hysterectomy and supravaginal amputation of the cervix in carcinoma of the cervix uteri. In 23 vaginal hysterectomies performed by him there were 3 deaths, while in 26 supravaginal amputations of the cervix all recovered. As regards the amount of mutilation incidental to the two operations, obviously vaginal hysterectomy involves much more mutilation than the high amputation of the cervix, and still more so if the uterine appendages are removed at the same time, as is the practice of some operators.

The indications for the Kraske method of extirpating pelvic growths as laid down by Bacon[2] are—1. When the uterus is too large to remove through the vagina and the tumor is impacted in the pelvis. 2. When carcinoma of the body of the uterus would infect the peritoneum if removed by any other

[1] Lancet, July 6, 1895.

[2] Am. Jour. Obst., Feb., 1895.

method. 3. When the carcinoma involves the vagina and uterus and sacral glands. 4. Pelvic dermoids or inflammatory deposits that have suppurated and opened into bladder and vagina or rectum. 5. Large tumors of the prostate. 6. Large paravesical tumors. 7. Malignant growths of the uterus involving the rectum. 8. Pelvic deformities, especially osteomalacia.

Borelius[1] has endeavored, by means of two modifications of the Rehn-Rydygier method—*i. e.* "the anterior and posterior sacral section," to restore the bony pelvis as well as the ligaments, as far as possible, to their normal condition; also to avoid paralysis of the bladder and rectum. He attained the latter object by means of an oblique resection from the lower border of the third sacral notch on the one side to the lower border of the fourth sacral notch on the other. In this way he preserved the function of the important fourth sacral nerve on one side. By this method he has operated upon 3 cases of cancer of the rectum and upon 4 cases of uterine carcinoma that could not be removed through the vagina.

Vaginal hysterectomy finds its most ardent advocate in Jacobs of Brussels. He is supported by a host of others, including Pichevin, Engelmann, Landau, and others. Jacobs[2] believes that vaginal hysterectomy is the best operation for the cure of uterine carcinoma, and that other methods are very rarely indicated. The contraindication for the operation is extension of the disease to other organs. The age of the patient is also important. When under 40 years of age hysterectomy should be performed only when the disease is in the beginning stage; after 55 years the progress of the disease is so slow that quite as good results are gained by the palliative as by the radical treatment. Jacobs[3] gives as the indications for the operation: 1. Uterine carcinoma; 2. Uterine fibroids; 3. Extrauterine pregnancy; 4. Total genital prolapse; 5. Inflammatory diseases of the appendages; 6. The chronic and incurable diseases of the appendages and of the uterus; 7. The diseases of the uterus after abdominal operation. He has performed the operation 403 times with 12 deaths, giving a mortality of 2.9%. In performing the operation for uterine carcinoma it is essential that there be integrity of the vaginal culdesac, complete mobility of the uterus, and a satisfactory general state of health. The great danger of the operation is the formation of fistulæ (peritoneal, vesical, ureteral, and intestinal). In his 403 cases he has observed 9 fistulæ after the operation. The instruments necessary for the operation[4] are a perineal retractor, 2 lateral retractors, a pair of strong scissors, 2 traction forceps, 6 long forcipressure forceps, a thermocautery. The vaginal mucosa is incised with the thermocautery all around the neck, for a good centimeter in length from the diseased tissues, as far as the cellular tissue. The bladder and rectum are freed by the finger, the anterior and posterior culdesacs are opened with scissors, and the broad ligament is divided with the aid of forceps. Richelot[5] publishes the results of 274 vaginal hysterectomies performed by himself.

[1] Centralbl. f. Gynäk., No. 34, 1895.
[2] Ann. de l'Inst. Ste. Anne, 1895, No. 2.
[3] Trans. Am. Gyn. Soc., vol. xx., 1895.
[4] Am. Gyn. Jour., Mar., 1896, p. 281.
[5] L'Union méd., Nov. 16, 1895.

Of these, 44 were for carcinoma, with 3 deaths; 61 were for suppurative diseases, with 5 deaths; 126 were for nonsuppurative diseases, with 5 deaths; and 43 were for fibromata, with 1 death. This gives a mortality in all cases of 5.1%. Schmid [1] reports the results of 42 cases in which vaginal hysterectomy was performed for carcinoma: 30 were carcinoma of the cervix, 7 carcinoma of the corpus uteri, and 2 a carcinomatous degeneration of myomata.

Russell [2] reports the clinical course of 47 cases of carcinoma of the uterus subsequent to hysterectomy. In 40 of the cases the vaginal route was adopted, the abdominal in 4, and the combined operation in 3 cases. 10% of the cases died from the primary effect of the operation; 44% are still living; 34% died with recurrence; 8% were not heard from; and 2% died from heart-lesion.

Infection in hysterectomy has attracted considerable attention, and in order to overcome this danger Mackenrodt [3] has adopted a method of hysterectomy by the cautery alone, without the use of permanent clamps or ligatures. This procedure he terms *igniextirpation of the uterus*, or [unphilologically] *thermocauterectomy*. This, while a new departure abroad, has been performed in this country by Byrne of Brooklyn [4] in several instances with success. Mackenrodt has performed 4 vaginal and 2 vaginoabdominal hysterectomies according to the following method: After thorough cleansing of the vagina the cancerous tissue is removed with the sharp spoon, the raw surface cauterized, and the vagina is again disinfected with soap and water, alcohol, and mercuric chlorid solution. If the introitus is narrow, more room is gained by deep lateral incisions made with the Paquelin at a white heat. The uterus is then drawn downward with a volsella, and Douglas's pouch is opened with the cautery. Then the lateral, and finally the anterior vaginal, fornices are divided in the same manner. The anterior vaginal wall is pushed upward with the thumb of the left hand, so as to put the attachments between the uterus and bladder on the stretch; these are divided by light touches with the Paquelin. The lower portion of each broad ligament is now included in a special form of clamp, and is burned through on the uterine side; after thoroughly charring the stump the forceps are removed, care being taken not to disturb the eschars. Any bleeding point is seized with forceps and again touched with the cautery. The uterus is now drawn downward still more, and the separation of the bladder and vesicouterine fold of peritoneum is completed with the cautery. Under the guidance of the fingers the upper portions of the broad ligaments are grasped in turn with the temporary clamps, and are separated as before, the intestines being meanwhile protected with gauze. Great care is necessary in cauterizing the stumps containing the ovarian arteries, and sometimes it may seem advisable to apply ligatures, although the writer has been obliged to do this in only 1 instance. The wound is dressed in the usual manner. When there are secondary deposits in the upper portions of the broad ligaments, Mackenrodt secures the uterine arteries from below, and when it is evident that firm adhesions are present he opens the abdomen and completes the operation from above.

[1] Centralbl. f. Gynäk., No. 43, 1895. [2] Johns Hopkins Hosp. Bull., Nov., Dec., 1895.
[3] Centralbl. f. Gynäk., 1895, Nos. 18 and 24. [4] Am. Jour. Obst., Oct., 1895.

Ries[1] objects to this operation on the ground that cancerous nests are left in a spot that cannot be attacked with the cautery—namely, in the iliac glands, lymphatic glands lying between the external and internal iliac artery and vein, the uppermost being usually at the bifurcation of the common iliac artery. They can only be removed after abdominal section. Ries therefore recommends a combined method, cauterizing from below, removing the uterus and appendages from above, and opening the peritoneum on the posterior wall of the pelvis, and digging out these glands from the connective tissue. Byrne[2] states that it would appear that uterovaginal structures that have been severed by the galvanocautery, or from which diseased portions have been excised by such means, are left in a state more favorable for restoration to a normal condition than when the scalpel or scissors has been employed.

AFFECTIONS OF THE PELVIC VISCERA.

Diagnosis of Pelvic Disease.—As Edebohls[3] has very aptly indicated, bimanual palpation forms the *sine qua non*, the very essence, of gynecologic practice. He would distinguish *diagnostic* palpation from *therapeutic* palpation, the latter embracing massage in its various forms, the bimanual reposition of the retroverted uterus without the aid of instruments, the divulsion of intrapelvic adhesions in narcosis after Schultze, and other procedures. In order to secure success in diagnostic palpation the bowels and bladder should be emptied, the garments loosened, and the patient resting upon a proper table in a suitable position. Obstacles to successful vaginoabdominal palpation are a short vagina, unusually high position of the uterus and of its adnexa, and a well-developed panniculus adiposus. These obstacles can in nearly every case be overcome by combined rectovaginoabdominal palpation. In practising the latter palpation the fingers of one hand are placed on the lower abdomen in the usual way; the index finger of the other hand is passed into the vagina, while the middle finger of the same hand enters the rectum; or the thumb may be passed into the vagina and the index finger into the rectum, at the option of the examiner. By means of this touch the examining fingers penetrate the pelvis to a much greater depth, the perineum being carried upward to the extent of about 3 cm. upon the web between the vaginal and rectal fingers; the rectal finger must penetrate beyond the third sphincter, the situation of which corresponds in height with that of the os internum. In *virgines intactæ* the bimanual examination assumes the form of a rectoabdominal palpation. In very fat women a transverse crease or furrow, deeply indenting the panniculus adiposus, exists just above the pubis, and in this furrow the finger-tips of the outer hand should rest, thereby facilitating the examination. To secure complete relaxation of the muscles of the abdominal wall the routine examination of patients with abdominal or pelvic tumors in a full hot bath is recommended and practised by F. Chlapowski. Edebohls would prefer examining the patient immediately after the emergence of the patient from the bath.

[3] Physician and Surgeon, Sept., 1895.

Demons[1] warns against taking the umbilicus as a fixed point in examining the abdomen. In 1 case he found the umbilicus below a line joining the iliac spines; the low position of the umbilicus led him to diagnose an ovarian tumor as a tumor of the mesentery. He has observed 4 cases in which a malignant tumor of the abdomen was associated with a secondary tumor of the same nature at the umbilicus. Bushbeck and Ettinger[2] conclude a clinical and diagnostic study of parametritic and perimetritic exudates with these practical observations: High fever of a pyemic type may exist for weeks, yet incision of the primary focus of infection may reveal the presence of serum only; this may contain only leukocytes or numbers of streptococcus-chains. Exudates of stony hardness may contain small quantities of pus or serum. Until the fluid is evacuated the temperature remains elevated. This fact explains the negative, or even harmful, effects of massage in such cases.

[Bacteriologic investigations are assuming a less important role in the work of the gynecologist than at one time seemed probable. According to Penrose,[3] the bacteriologic study of inflammatory diseases of the Fallopian tubes and ovaries has not only enlarged somewhat our knowledge of the pathologic processes affecting these structures, but promises to be of practical value in the treatment of the morbid conditions (see Plate 6). The pathogenic organisms that are found in inflammation of the uterine appendages are the gonococcus, the streptococcus, the staphylococcus, the bacillus coli communis, the tubercle bacillus, and the pneumococcus. Bacteriology has demonstrated that the pus—in suppuration of the uterine appendages—does not contain microorganisms in every case; and, secondly, the danger of peritoneal infection from the pus of a pelvic abscess is dependent upon the variety of organism present. A microorganism is present at some stage of the pathologic process in every case of suppuration of the uterine appendages; as the disease progresses, however, the microorganism dies and disappears and the pus becomes sterile. Such a result probably occurs in every case that runs a chronic course for a sufficient time. It seems probable that an acute attack of inflammation in a chronic case is accompanied by the presence of active microorganisms, and in any chronic case there is always danger of infection by the bacillus coli communis passing through an adherent intestinal wall. The cases in which Penrose has found microorganisms have been those in which decided constitutional and local symptoms were present before the operation. These symptoms are pyrexia, coated tongue, rapid pulse, and marked pelvic and lower abdominal pain and tenderness. A fact of practical importance is, that microorganisms may be found not only in the pus of a pelvic abscess, but in the substance of the abscess-wall; the pus may be free from organisms, while they are present in the wall. The danger of peritonitis or of peritoneal sepsis after intraperitoneal rupture of a tubal abscess is dependent upon the character of the microorganisms found in the pus. The danger may be nothing or very great. The pneumococcus seems to be virulent in the peritoneum;

[1] La Sem. méd., 1895, No. 40, p. 342. [2] Arch. f. Gynäk., 1896, B. i. H. 2.
[3] Am. Gyn. and Obst. Jour., Aug., 1895.

the gonococcus seems to be of but doubtful danger to the peritoneum. The staphylococcus, streptococcus, and bacillus coli communis are the organisms that usually cause peritonitis or peritoneal sepsis, and are, especially the last named, very virulent. Peritoneal sepsis depends not only upon the character of the organisms that have entered the peritoneal cavity, but also upon the character of the fluid in the peritoneum and the condition of the serous surface. The healthy peritoneum has the most extraordinary power of absorption, and peritonitis is most likely to occur when there has been chemical or mechanical injury to the absorbing serous surface, when a good culture-medium remains in the peritoneal cavity. Extravasation of blood or serum in the peritoneal cavity, long exposure of the peritoneum, and damage to the serous surface, all aid the development of peritonitis.

Bard[1] of Lyons calls attention to the method of **lumbo-abdominal palpation** in the diagnosis of peritoneal effusions. The patient is placed in a sitting posture, bending slightly forward. The examiner places one hand on the back in the situation of the quadratus lumborum, close to the vertebral column. His other hand is placed on the various parts of the abdominal wall in front. The impulse transmitted by the impact of the hand, placed posteriorly, is felt with ease and clearness by the anterior hand when ascitic fluid is present, just as it is in palpation by the ordinary method. The transmitted wave is felt badly or not at all from before backward, except in extremely abundant effusions. The pressure, therefore, is to be made always with the posterior hand, from behind forward. The method is capable of detecting very early and slight effusions, inaccessible to other procedures, if the anterior hand be placed low down on the hypogastric region just above the pubis. It is also particularly useful in cases of extreme ascites, when the tension is such as to prevent the palpation of the peritoneal contents. When solid masses are interposed in the trajectory of the lumbo-abdominal wave it is not perceived or is extremely feeble. In such a case the wave may be clearly perceived on one side, and be completely absent on the other, while the ordinary anterior method fails to distinguish any difference between the two sides. In this manner there may be gained a knowledge of the existence of a solid mass in the peritoneal cavity, and various modifications of the method may be employed for the differential diagnosis of ovarian cysts and other intraabdominal collections of fluid from peritoneal effusions.

The Influence of Castration on Structural Changes of the Uterus.—Sokoloff[2] presents the results of a series of interesting experiments upon bitches and rabbits, undertaken with the view of determining the anatomic changes that take place in the uterus after the removal of one or of both ovaries. After the former operation the heat returned as before, but in no instance after the removal of both ovaries. The animals were killed at different periods after the operation, varying from 20 days to 14 months; their uteri were removed and hardened, and sections were made. No variations from the normal were noted in cases in which a single ovary had been removed, but

[1] L'Union méd., No. 37, 1895.

[2] Arch. f. Gynäk., Bd. li. H. 2, 1896.

after complete castration a well-marked atrophy of the circular muscular layer was observed, which reached its height 4 months after operation, as well as a disappearance of numerous muscular fibers in the longitudinal layer. The caliber of the vessels was diminished and their walls were thickened, especially in uteri removed several months after castration. The endometrium remained unchanged even a year or more after the operation. Sokoloff denies that the atrophy of the uterus following castration is due to ligation of the spermatic arteries, since the collateral circulation is speedily restored. It must, then, be attributed to a disturbance of nutrition in the uterine tissue, secondary to extirpation of the ovaries, of nervous origin, either central or dependent upon the removal of vasomotor or trophic centers in the ovaries themselves. The writer favors the latter theory. Every tissue must, in order to retain its normal structure, perform its normal functions as well as receive a proper amount of nourishment. When the normal physiologic stimulus of this tissue is absent and its function is accordingly suspended, it undergoes atrophy, even though its nutrition be not disturbed. The regular rhythmic contractions of the uterus cease after extirpation of the ovaries which are the seat of the exciting impulses; its normal functions, menstruation and pregnancy, are eliminated, and muscular atrophy results. The endometrium, not being influenced by these contractions, remains unchanged. The latter phenomenon may be explained on the theory that the mucosa and utricular glands are presided over by a special nerve-center independent of the atrophic center regulating the muscular tissue.

Hysterectomy for Suppurative Disease of the Pelvic Organs.—In considering the important matter of the substitution of hysterectomy, abdominal or vaginal, for salpingo-oophorectomy, to effect a permanent cure of inflammatory diseases of the uterus and its adnexa, Norris[1] remarks that the test as to the value of the two operations is the comparative ultimate results, and states that the cases are now sufficiently numerous to indicate a favorable verdict for hysterectomy. It has been the experience of all operators that in many cases after the removal of both tubes and ovaries the patients have not been completely cured. Their pain and discharge have remained, and the various courses of constitutional and intrauterine medication have failed to ameliorate the condition. Only after the performance of a secondary operation for the removal of the uterus will relief of the symptoms follow. He further states that the shock following the more radical operation is usually not greater, and often is less, than after salpingo-oophorectomy; that convalescence is more satisfactory; that the liability to hernia is less, since drainage is seldom necessary; that the nervous disturbances of the enforced menopause are less troublesome; and, finally, that ultimate cure is more often obtained. The conditions of the pelvic organs that make it necessary to remove the uterus are not very numerous, yet one or all of these conditions will accompany most cases of long standing and some acute cases of pelvic inflammation. As a rule, it is best to remove the uterus along with the broad ligaments, tubes, and ovaries when

[1] Univ. Med. Mag., Dec., 1895.

the womb is enlarged and its walls are infiltrated, or when it is so densely adherent to adjacent structures that their enucleation seriously injures the uterine tissue or interferes with its blood-supply. While, however, a very large proportion of cases of pelvic inflammatory disease are suitable for hysterectomy, it must be remembered that this operation requires much skill and good judgment, the risk being greater in proportion to the operator's inexperience and the patient's inability to stand the necessarily longer administration of the anesthetic. Van de Warker[1] believes that in many cases of marked pelvic disease the uterus should be removed—not because it is diseased, but because by the removal of the organ the cellular pelvic spaces are opened up and the necessary drainage afforded to the cellulitis there existing. In his opinion, hysterectomy affords the only route to this area of intrapelvic inflammation. He claims that there is a simple diagnostic sign which when discovered is proof of the presence of cellular inflammation and indicates the removal of the uterus. The infiltrated cellular spaces, whether in the broad ligament extending laterally into the iliac fossa, or draining through connective-tissue spaces into the vaginal septum, or through the pubosacral areolar process to the lateral surfaces of the vagina, may be brought up between the finger in the rectum and the thumb in the vagina as thickened, indurated, and doughy masses. The vaginal cellulitis shows as a slightly elastic mass firmly fixed to the pelvic wall, smooth and glistening, the vaginal rugæ obliterated.

Hysterectomy in Puerperal Sepsis.—In advocating the performance of hysterectomy in certain selected cases representing the suppurative group of puerperal septicemia, Baldy[2] remarks that with tubes and ovaries distended with pus abdominal section and removal of the offending organs become necessary; if, in addition, the broad ligaments and pelvic floor be infiltrated and contain pus, while it is true that the entire area of infected and suppurating connective tissue cannot be removed, those who have performed total hysterectomy in this condition will recall the fact that a large proportion of the infiltrated area has been reached, and that the remaining portion is in every direction opened up and left in a most favorable condition for drainage. No method of incision, either single or multiple, will so thoroughly lay open and afford such thorough drainage of the suppurating tissues as the removal of the entire uterus. The plea that when once the infection has passed into the connective tissue the disease has ceased to be a local one, and has become general and beyond reach, is not absolutely true, at least in the reasonably early stages. The disease is essentially a local one until such time as the blood is so broken down by the absorption of septic matter as to longer preclude the possibility of life. When that point has been reached is the difficult problem to be solved. If the physician decide that, provided there be no more absorption of sepsis, the patient's chances for life are good, it would then seem that instead of wasting invaluable time in "building up" the woman or "waiting," it becomes his duty to see that there be no more absorption, or, if perchance absorption cannot be stopped

[1] Buffalo Med. Jour., July, 1895.

[2] Am. Jour. Obst., July, 1895.

altogether, that at least it be minimized. Total hysterectomy is the best way of accomplishing this object, and, as a rule, the best time for performing this operation is within the first week or two. Equally, if not more, difficult cases to deal with are those in which no disease of the pelvic peritoneum, Fallopian tubes, ovaries, or connective tissue is demonstrable by an examination. The absorption of septic material is taking place from the cavity of the uterus, as demonstrated by the absence of all other cause and the presence of purulent and fetid discharges. The so-called diphtheric and gangrenous cases are of this variety. Intrauterine douching, curettage, the free use of pure carbolic acid to the interior of the uterus, and drainage by gauze-packing or otherwise, having failed to bring about a diminution in the high temperature and pulse, there remains nothing short of hysterectomy to put a stop to the disorganization of the blood. The hysterectomy need not of necessity be total, amputation below the internal os being all-sufficient. Twenty cases have been reported by American operators with 7 successes. Cartledge[1] concludes that the time for hysterectomy in true puerperal infection is after thorough local and general treatment has failed to stay the progress of the disease. If successful, the nonoperative treatment will arrest the disease in 3 days. The operation he would prefer to do by the vaginal method. Holmes[2] admits that hysterectomy alone, in certain cases of puerperal sepsis, will accomplish the removal of the infected tissues. He states that in 101 cases of sepsis treated by Braun-Firnwald curetting failed 5 times, and in these 5 cases there is every reason to believe that hysterectomy would have been effectual in saving the lives of the patients. The question of treatment of puerperal sepsis by hysterectomy is one that vitally concerns at least 214 persons a year in Chicago, 208 persons a year in New York City, and 78 persons a year in Brooklyn. In conclusion, he claims that the indications for hysterectomy in puerperal sepsis seem to be these: (*a*) Curetting and uterine irrigation and tamponade have failed; (*b*) Peritonitis or pelvic cellulitis is present; (*c*) Hopeless localization of infection outside the pelvis cannot be found. The operation may not be helpful in the course of diphtheric vaginitis and endometritis, in cases of rapid early infection, and in cases of septic phlebitis reaching outside the pelvis. The method of operating will depend upon the size of the uterus, upon the condition of the uterine tissues, and upon the experience or choice of the operator. Holmes would also prefer in most cases the vaginal route.

Albert H. Tuttle[3] concludes that while the indications for extirpation of the uterus for puerperal sepsis must be extremely rare, there are conditions found at times that are good and true indications for hysterectomy. The extension of the operation, however, must be extremely limited until our knowledge of the intimate relations between the types of infection, their clinical manifestations and pathologic lesions, is better formulated and good enough to enable one to make a sufficient diagnosis. Baldy[4] remarks that it is a well-known fact that the vast majority of cases of puerperal infection

[1] Am. Gynæc. and Obst. Jour., Jan., 1896. [2] Jour. Am. Med. Assoc., Nov. 23, 1895.
[3] Boston M. and S. Jour., Dec. 5, 1895. [4] Phila. Polyclinic, Nov. 9, 1895.

recover under medical treatment, including the minor surgical treatment by curettage. It is equally well known that a certain smaller proportion of patients die of septicemia within a week or two from the time of delivery. It is in respect to the treatment of this latter class of cases that differences of opinion are found among experts. It will be noted, however, that while a few denounce any major surgical interference in any case at any stage of the disease whatever, a large majority of those competent to judge advocate hysterectomy in certain well-defined cases. It may be concluded that hysterectomy is the treatment demanded in all cases of puerperal septicemia in which it can be demonstrated that there is no suppuration of either the Fallopian tubes, the ovaries, or the peritoneum, when the patient's life is seriously threatened, other approved methods having been tried and failed, and in all cases in which the uterine walls contain pus-pockets, whether there be other foci of suppuration or not. Early decision and operation are necessary to success. Hirst[1] considers that the present status of hysterectomy for puerperal sepsis may be thus defined: For the acute rapidly progressive and virulent form of sepsis early in the puerperium (almost always a mixed infection of the endometrium) the operation so far has been a failure; for suppurative and ulcerative metritis, usually but not necessarily appearing in the latter part of the puerperium, it has been a brilliant success. Penrose[2] reports a case of hysterectomy for acute puerperal sepsis in a young woman of 24 years, the operation being performed on the fifth day; recovery followed.

Vaginal Incision for Pelvic Disease.—Much has been written upon this subject during the year, and preeminent among the papers upon this so-called epidemic of transvaginal surgery are those of Henrotin,[3] Norris,[4] Gilliam,[5] A. Martin,[6] Polk,[7] Garceau,[8] Vineberg,[9] Montgomery,[10] and Long.[11] Norris, in opposition to the most ardent advocates of vaginal section (or, as it has been termed by Dührssen and A. Martin, *anterior kolpotomy*), who consider it applicable to all possible intrapelvic diseases, and even to intra-abdominal tumors, believes that its legitimate field will be more restricted. The operation may be indicated for long-standing cases of inflammatory pelvic diseases, in which there have been repeated attacks of peritonitis, with dense adhesions and pus-formations that may have spontaneously opened into the bowel, bladder, or vagina. Evacuation and drainage here will often be useful as a preliminary measure, to be followed, if need be, by an abdominal section after the patient has gained in strength and flesh. To attempt by the vaginal route to remove diseased adherent organs in such cases is dangerous, urinary and fecal fistulæ often following these operations. Norris believes that it is possible that before long local treatment for a displaced and adherent uterus, tube, and ovary will be discarded, and that the organs will promptly be examined and

replaced through an incision in the vaginal culdesac. It is probable, also, that fibroids, especially those capable of passing the inferior strait of the pelvis, will always be enucleated or morcellated and be removed through the vagina, and that the same method will be employed in many cases of tubal and ovarian disease. The remarkable work of Péan, Ségond, Jacobs, and others, by vaginal section for pelvic inflammatory diseases, has led gynecologists the world over to a serious consideration of the advantages claimed for vaginal hysterectomy in dealing with the various intrapelvic inflammatory diseases for the cure of which abdominal section has hitherto been applied. Jacobs has given the mortality in 816 cases of suppurative diseases of the appendages treated by vaginal hysterectomy at the hands of 6 operators as 4.5%. In 584 cases of non-suppurative diseases of the appendages the mortality was 1.7%. Henrotin, after observing the methods adopted by the leading gynecologists of this and other countries, remarks that "a patient who has not had her abdomen opened, who has no scar left that she can see, will have been less profoundly shocked, will be conscious of less traumatism, will feel easier and quieter, and will in most instances be more quietly, completely, and perfectly cured. This is the observation of men who have performed large series of vaginal hysterectomies, and who at the same time frequently perform abdominal sections." The few cases of sepsis that occurred while the operation was still in its experimental stage have almost entirely disappeared, since the value of careful packing of gauze in the pelvis beyond the ends of the forceps has been recognized. The seat of the operation is thereby almost entirely shut off from the general cavity, the stumps of the broad ligament and the instruments being really in the vagina. Infected tissue, he claims, is not left behind more frequently by the vaginal than by the abdominal method. The danger of abdominal operations in cases in which there exist openings into the rectum or bladder, discharging the most foul pus through these organs at irregular intervals, is well recognized. It is in such cases that the French have insisted upon the propriety of removing the uterus, and, if possible, the appendages, through the vagina. This affords a straight, large, and efficient channel for drainage, which in almost every instance sooner or later completes the cure. Henrotin urges the adoption of the vaginal operation for the following reasons: 1. In the variety of cases to which it is particularly applicable it is less dangerous than abdominal section. 2. It avoids to a great degree the contamination of the general abdominal cavity by a less disturbance of the exudate, and consequently protects the unaffected portion. 3. It produces less shock, and is therefore applicable to patients much debilitated by the existing disease. 4. It does away entirely with the abdominal scar, and therefore with the liability to hernial protrusion. 5. In common with hysterectomy by other methods, it results in a more certain, rapid, and complete cure than mere removal of the appendages. 6. It is decidedly preferable and less dangerous in cases complicated with fecal, urinary, and vaginal fistulous tracts. 7. It has proved successful in many cases in which abdominal section in the hands of the most skilful operators has failed. Henrotin concludes: "To see Baldy, Howard

Kelly, Baer, Krug, Eastman, and many others remove a fibroid tumor by our modern perfected abdominal method is, indeed, almost perfection; but to see Ségond or Jacobs do the same with a loss of scarcely a tablespoonful of blood, and bearing in mind that not a ligature will remain within or a scar be visible, is almost a revelation."

Gilliam[1] remarks that sepsis is less frequent in transvaginal surgery, because (1) the pelvic peritoneum is better able to cope with germs; (2) the route of invasion is less direct and against the tide of outflowing serum; and (2) the germicidal powers of the splanchnic viscera are unabated. Abdominal drainage, on the contrary, is against gravity, and the animal fluids coating the tube or filling the meshes of the gauze afford an excellent culture-medium for stray germs that naturally make their way downward or inward. Gilliam believes that vaginal surgery has a sphere of its own. It cannot aspire to supplant abdominal surgery nor yet in any large measure trench upon it. The dangers of the operation, according to Long,[2] are opening a viscus or blood-vessel and opening the peritoneum, thereby infecting it. Polk[3] believes that the vaginal section will always serve as subordinate to the abdominal, even though it diminish the frequency of the latter one-half to two-thirds. He remarks that as the indications for or against depend largely upon the dimensions of the diseased area or growth, one must admit that the earlier the operation is done the greater the chance for vaginal section. Since February, 1892, 72 vaginal sections have been performed at Bellevue Hospital, with 3 deaths, covering every species of disorder for which the operation has been advocated. Polk tabulates the conditions favorable, on the one hand, to vaginal section, and on the other to abdominal section in diseases of the female pelvic organs, as follows:

Vaginal Section.	*Abdominal Section.*
A shallow and wide pelvis in a thin woman.	A narrow and deep pelvis, especially if deformed.
Explorations of the pelvis.	Explorations above the true pelvis.
Visceral adhesions in the true pelvis.	Visceral adhesions in false pelvis or above.
Displaced and adherent uterus.	Large ovarian cysts, especially multilocular, with colloid contents.
Smaller ovarian cysts, especially the intraligamentous and parovarian.	Large fibroids, especially the firm and hard.
Smaller fibroids, especially the soft.	
Extrauterine pregnancy up to the 7th month and after death of the fetus.	Extrauterine pregnancy at the time of rupture and at term.
	Extrauterine pregnancy, with the tumor wholly above the brim of the pelvis, and not in relation with the uterus.
Pelvic hematocele.	Pelvic abscess pointing upward.
Puerperal hysterectomy.	Conservative operations under conditions unfavorable to vaginal section, such as a narrow and deep or a deformed pelvis that is contracted.
Acute inflammation of the appendages, with peritonitis involving the culdesac.	

[1] Loc. cit. [2] Loc. cit. [3] Loc. cit.

Vaginal Section.	*Abdominal Section.*
Inflammatory destructive disease of the appendages, including tubercular disease.	
Pelvic abscess pointing downward.	
Conservative operations on appendages that lie in the true pelvis.	

Vineberg reports the first fatal result after anterior kolpotomy. A. Martin[1] has operated on 149 cases without a death; Aman[2] has had 43 cases, Mackenrodt 30 cases—making a total of 264 cases, with 1 death, giving a mortality of 0.37%. In operating Vineberg prefers a longitudinal incision in the anterior wall instead of a transverse incision either in the anterior or posterior fornix, because it affords more room; it cannot wound the ureters or the rectum; it is attended with less hemorrhage; and it affords the best method of doing a vaginal fixation when there is an accompanying backward displacement of the uterus. Burrage[3] regards the vaginal incision as adapted only to cases of cystic ovaries; prolapsed and adherent ovaries and tubes; peritonitic adhesions that limit the mobility of the uterus; small ovarian and parovarian cysts; mild grades of salpingitis; and for diagnosis in doubtful cases. When the inflammation of ovary and tube has progressed to the extent of forming a hard tumor surrounded by exudate, and when the disease is high up in the pelvis, the proper operation is either abdominal section or vaginal hysterectomy. Watkins[4] states that the operation is indicated—(1) When the condition of the patient is such as to make abdominal section extremely dangerous. (2) When the abscess is large, of long standing, and situated low in the pelvis, and when the patient gives a history of peritonitis. (3) When abdominal section reveals extensive and firm intestinal adhesions. (4) When the abscess is on the floor of the pelvis and is complicated by rectal fistulæ. (5) Vaginal section may be indicated for the separation of adhesions that fix the ovaries and tubes on the floor of the pelvis, and for examination of the ovaries and tubes. (6) Puerperal abscess. These abscesses frequently involve the tubes and ovaries, and satisfactory results usually follow thorough drainage of them. Quénu[5] says that a good general rule is, if the uterus be movable, to perform abdominal section.

A. Martin,[6] who has performed anterior kolpotomy more frequently than any other operator (109 cases), adopts the following technic (see Fig. 116): The patient is placed in the dorsal position, with the legs raised on either side. A speculum being introduced into the vagina, the uterus is fixed with a pair of Orthmann's forceps, a combination of a uterine probe and volsella which grasps the anterior lip of the cervix so that one can draw down the cervical portion of the uterus to the vaginal introitus. Another pair of volsella forceps are fastened just under the orifice of the urethra, about 3 in. from the cervical opening. The anterior vaginal wall is pulled upward; a fold is raised which is to be incised vertically and peeled off laterally from the surface of the blad-

[6] Loc. cit.

der and cervical body. Hard fibers will be seen above the vaginal incision, which are to be divided. The upper border is then pushed upward with the finger, separating the loose tissue between the bladder and uterus, thus carrying the former up out of the way behind the symphysis pubis. Occasionally the bladder is distinctly made out, at other times it is never seen. The peritoneum

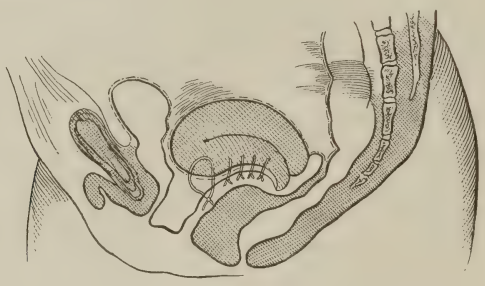

FIG. 116.—Anterior kolpotomy: method of suturing (Berl. klin. Woch., 1896, No. 1).

is found in the form of a fold between the bladder and uterus, recognizable by its pellucid appearance; this is to be opened, when the abdominal cavity and contents are exposed to view. After treating the pelvic condition the wound is closed in the following manner: The uterus and adnexa are to be replaced in the abdominal cavity by pressing on the anterior uterine surface. A strong catgut suture is to be carried with a curved needle through the upper end of the vaginal wound, the cellular tissue at the base of the bladder, the peritoneum, and the anterior uterine wall near the fundus, taking a good hold of it, and out again on the opposite side in the same manner, and tied. Two other sutures close the vaginal wound, connecting it with the anterior surface of the corpus uteri; a fourth the cervix. A running catgut suture is used to close the vaginal wound more exactly between these deep sutures. Martin recommends the operation in cases of myomatous tumors, which, if of large size, may be removed by morcellement; to replace movable retroflexed uteri, which may then be retained by vaginal fixation; to break up peritoneal adhesions fixing the uterus; for procidentia (in these cases a part of the vaginal wall is excised to make it of the proper length, the uterus is fixed in the upper part of the vaginal wall, which is very little disturbed, and the weight of the uterus is thus taken from the remaining portions, retaining it in its normal position); for opening cystic ovarian tumors and performing ovarian section; and in treating diseases of the tubes.

Dührssen,[1] in performing vaginal hysterectomy for extensively diseased adnexa, overcomes most of the difficulties arising from the narrowness of the vaginal passage by incision of the vagina and perineum performed as follows: A point is marked on the skin halfway between the anus and the tuberosity of the ischium. The sides of the vulva are then retracted; a knife is inserted at the posterior commissure of the vagina and carried backward and outward to the point previously marked on the skin. This incision cuts the levator ani

[1] Arch. f. Gyn., xlix. No. 2, p. 324.

muscle and opens the ischiorectal fossa. Hemorrhage is stopped by pressure of a broad retractor. The incision is closed by a row of silkworm-gut sutures passed through the skin and muscle, and a row of catgut sutures in the vagina. This incision usually gives plenty of room, but more space may be obtained by multiple superficial incisions of the edges of the vaginal wound or by a longitudinal incision of the anterior wall of the vagina, and separation of the vagina from the bladder. These incisions remove all resistance of the soft parts, and allow the removal of a uterus the size of a child's head, without previously cutting it in two or without using forceps for stopping the hemorrhage.

There are various other methods of performing this operation, depending much upon the condition found in each particular case. *Method of Péan:* If the uterus is not fixed and small, he employs the ordinary clamp method. When there are adhesions, pyosalpinx, etc. the uterus is removed by morcellation—*i. e.* by making transverse incisions in the uterine wall after clamping with forceps. The tubes and ovaries are then separately removed. *Method of Ségond:* After separating the cervix, dissecting back the bladder, and ligating the uterine arteries, conical portions of uterine tissue are excised until the fundus is reached, when the surrounding tissue and upper portion of the broad ligaments are ligated. *Method of Doyen:* When Douglas's culdesac has been opened and the bladder displaced, the anterior wall of the uterus is incised in the center and separated and the tissue on each side is clamped. The incising, separation, and clamping progress from below upward until the fundus is reached. If the uterus is very large, a V-shaped portion of the anterior uterine wall is excised. The cervix is drawn progressively downward, clamps are applied to the broad ligaments, and the uterus removed. *Method of Müller-Quénu:* This differs from the foregoing in that the uterus is completely divided into two halves, anterior to posterior. In all 4 methods, after opening the posterior vaginal vault, a thorough bimanual examination is made to determine the condition of the tubes and ovaries. If the vagina is too small, a lateral incision is made. Drainage is unnecessary except when there is pus. Drainage by partial resection of the uterus is condemned. The after-treatment is as usual. Complications, such as injury to the intestines, bladder, and ureters, are not more common than in abdominal section. Secondary hemorrhage and prolapse of the vagina between the clamps are uncommon, and if a fistula results it is easily repaired. The mortality of vaginal hysterectomy for suppurative adnexal disease is from 8.03% to 12.5%. Bourdon's mortality with this method of treatment for pyosalpinx and ovarian abscess is 3.8%, and in noninflammatory diseases he has not lost a case. The final results are good. Ségond, with 128 cases, reports 118 perfectly well.

Interesting cases of *abdominal section* are reported by Hauck,[1] Cullingworth,[2] Kousmine,[3] Kraft,[4] Schwartz,[5] Edge,[6] Malcolm,[7] Gersuny,[8] William

C. Wood,[1] Prince,[2] Reifsnyder,[3] Owens,[4] Kahn,[5] and Weber.[6] Hauck reports a successful abdominal section with appendicectomy in a child 16 months old, the symptoms being those of intestinal obstruction caused by a coil of small intestine encircling the ascending colon and drawing it up toward the liver. Successful ovariotomies in aged women are reported by Owens and Kraft. Owens's patient was in her 87th year, the oldest reported case. An interesting feature of this case is that 6 years previously the doctor had removed from her right side a parovarian cyst, which he had shelled out of its nest. Section showed that the new growth arose from the right ovary, instead of from the left, as was supposed. Kraft's patient was 84 years old; her tumor was of 7 years' growth, and had been tapped several times. Reifsnyder describes 2 cases of ovariotomy performed on native Chinese women in the Margaret Williamson Hospital, Shanghai, both recovering. The first patient was 23 years old, and her tumor weighed 80 pounds. The second patient was 25 years of age; she married at 19, and soon afterward her abdomen began to enlarge. She had never been tapped. She was 4 feet 8 in. in height, and the circumference at the umbilicus was 5 feet, $7\frac{3}{4}$ in. She passed about 16 ounces of urine in 24 hours, free from albumin; its specific gravity was 1026. Her appetite was good and the bowels acted once or twice daily. She had been unkindly treated as a sterile woman unfit for domestic work. After numerous precautions ovariotomy was performed. Chloroform was given; her head and shoulders had to be somewhat elevated; she took but little of the anesthetic; 88 quarts of fluid were removed; the tumor consisted of 1 large and 1 very small cyst; there were free adhesions superiorly. The empty tumor weighed $6\frac{1}{2}$ pounds. There was no ascitic fluid in the abdominal cavity. The pedicle was long and about $2\frac{1}{2}$ in. broad. The abdomen was washed out, then the wound closed with 12 silk sutures. There was much shock at first. After the first day she passed urine voluntarily, and her bowels were moved 41 hours after operation. On the second day there was flatulent distention, the pulse rising to 102. Rochelle salts were given. Her second night was the worst; she had 2 hypodermic injections of digitalin ($\frac{1}{100}$ gr.), brandy by the mouth twice, one turpentine enema, and a capsule of turpentine taken by the mouth. Afterward she did well. Her weight 2 months after the operation was 92 pounds.

Prince reports the *calcification of an ovary* lying free in the pelvic cavity of a woman 40 years of age. It was situated posteriorly to the uterus, and had become detached, together with the accompanying tube (the left), probably from some constricting agency. All vestige of any constricting band or of the amputated tube had disappeared. Weber's case was one of femoral hernia of a cyst of the broad ligament, which he believed had its origin in the so-called duct of Gärtner. The femoral ring was not enlarged, the cyst-wall having grown or been forced into and partly through the femoral canal, result-

ing in an hour-glass formation. Kousmine reports a large tumor of the ilio-femoral region caused by a hernia of the Fallopian tube in a woman 36 years of age. Only 5 other such cases are reported. Edge[1] reports a case of post-partum tuboovarian abscess situated high on the left pelvic wall and in the left iliac fossa; Douglas's pouch was empty. A fecal fistula followed the operation, gradually closing spontaneously. Wood[2] calls attention to a hitherto undescribed symptom of pyosalpinx—namely, a severe pain over the region of the liver, which has been present in all of his cases.

F. B. Robinson[3] reports 45 cases upon which he has performed his new operation of removal of the appendages and ligation of the uterine artery to the uterocervical junction. The utility of the operation resides in the following points: 1. It checks hemorrhage; 2. It arrests menstruation; 3. It elevates the uterus; 4. It causes shrinkage of the uterus; 5. It avoids the removal of uterine myoma; 6. It avoids vaginal hernia. Edebohls[4] prefers the rectus muscle as the site for the abdominal incision.

[**The ligature in abdominal section** still commands much attention from operators.] Penrose[5] objects to the methods of ligaturing commonly employed, on the grounds that the sutures are liable to slip; there is difficulty, or impossibility in some cases, of removing all the ovary and tube; the broad ligament is puckered up and made more tense than normal, and may for this reason cause subsequent pain and discomfort; and an unnecessary amount of tissue is strangulated. These objections may all be avoided by ligating the distal and the proximal portions of the ovarian arteries with distinct ligatures, and then cutting away the tube and ovary. The first ligature is passed through the broad ligament near the pelvic wall, securing the proximal portion of the ovarian artery; the second ligature is passed through the broad ligament at the uterine cornua, securing the distal portion of the artery. The second ligature may include the Fallopian tube if there be no disease of the isthmus, or it may be passed immediately beneath the tube if it be necessary to exsect the tube from the uterine cornua. There is no tendency to retraction or slipping; the minimum amount of tissue is included in the ligatures; all ovarian tissue can be removed; and there is no traction whatever upon the scar. Noble[6] prefers closing the abdominal wall by means of buried silkworm-gut sutures placed at the level of the aponeurosis, thus closing the peritoneum, subperitoneal fat, recti muscles, and aponeurosis. The skin and subcutaneous fat are then brought together by superficial sutures introduced down to the aponeurosis, so that dead spaces shall not be left in the abdominal wall. His results with this method have been very satisfactory. Edebohls,[7] however, who formerly strongly advocated the use of the buried ligature, now repudiates the buried *permanent* ligature, and employs buried chromicized catgut instead. Longyear[8] has employed buried sutures and ligatures of kangaroo

tendon for the past 4½ years in 57 cases of abdominal section, with and without drainage, and he has yet to see his first case of postoperative hernia. He has also employed the tendon in a large number of operations for ruptured perineum and in a number of cases of herniotomy.

Drainage.—[The question of drainage after abdominal section, while practically settled, still gives occasion for considerable controversy.] Writes Senn:[1] "Drainage of the abdominal cavity is an expression of the present imperfect state of surgery." He remarks that it should be limited to appropriate cases, and should be employed as little as possible. When he drains for pus, whether through the abdominal or pelvic incision, he invariably resorts to tubular drainage, and for the removal of serum combined drainage; while capillary drainage by means of a tampon is reserved for cases in which it becomes necessary to arrest hemorrhage by this method. Van Hook[2] prefers capillary abdominal drainage for several reasons. A very great advantage of the gauze drain lies in the fact that its presence, by favoring the destruction of a certain number of peritoneal cells and of white corpuscles, brings about a rapid coagulation that materially favors the arrest of hemorrhage. The gauze has an important advantage, also, in that it may be harmlessly pushed in various directions in the abdominal cavity. The gauze should be left in the abdominal cavity as long as the discharge is free. The gauze should be as actively "hydrophile" as possible, to prevent its acting as an obturator instead of a drain. The strips of gauze should be left long in order that the fluid from the peritoneum may be delivered with great freedom and rapidity into the dressings. Duret[3] has recently successfully employed aspiration according to the method suggested by Lawson Tait—namely, by a hydrocele-syringe every 4 hours for 2 or 3 days. Grandin,[4] Mallett,[5] and Watkins[6] favor drainage by the vaginal route. Watkins mentions as the advantages of such a method that the most dependent portion of the abdomen is drained; the drainage is downward; the surface that usually requires drainage is in more or less close proximity to the vagina; the danger of hernia is diminished; fewer adhesions must of necessity occur, as the abdominal cavity is kept more free from exudates; there is less danger of infection of the abdominal wound; when the gauze drain is employed much less pain is occasioned upon removal of the drain; and there is less danger of infection in the after-treatment of the patient. He regards the abdominal route as preferable when the surface to be drained is near the abdominal incision. Penrose[7] determines when to employ drainage by bacteriologic examination of the pus during the operation whenever intraperitoneal rupture of the abscess takes place. If the abscess can be removed without rupture, drainage is unnecessary; if rupture occur and the contents are sterile, the pus is merely sponged out and the abdomen closed; if rupture occur and the contents are

PLATE 6.

Appearance of a drop of pus examined during operation (Am. Gyn. and Obs. Jour., Aug., 1895).

septic, the pelvis is washed with distilled water or sometimes with a 1 : 2000 bichlorid solution, and is drained with the glass tube or with gauze. In the examination cover-glass preparations are made, and are fixed in the flame of an alcohol lamp, and stained with carbol-fuchsin. A Leitz one-twelfth immersion lens is used. The illustration (see Plate 6) shows the microscopic appearance of a drop of septic pus examined during one of his operations.

Czempin[1] notes that drainage is being less and less employed each year. He refers to the method advised by Sänger (the glass drain) and Mikulicz (the iodoform-gauze drain), and also to the indications for drainage as pointed out by Veit, Olshausen, and Martin. He notes that Sänger has practically discarded drainage; that Veit believes the indications are very few; and that opinions are so varied that there are no absolute rules to follow in any particular case. Czempin has found that each year fewer cases require the drainage-tube. From his observations the cases in which drainage may be indicated are divided into two great groups: *First*, operations upon noninfectious tumors with unfavorable complications, caused by the condition of the relations of the operation wound. *Second*, operations upon infectious tumors or those thought to be infectious, and operations complicated through injury to the intestine, the escape of pus or decomposed fluid. First, complicated noninfectious operations. To this group belong (*a*) intraligamentary-developed new growths resulting in the necessary extensive separation of the pelvic connective tissue; (*b*) where the new growth has extensive adhesions with neighboring organs and the parietal peritoneum, therefore necessitating extensive injury to the peritoneum. Under these headings Czempin reports a series of cases with results that vary too much to be of practical use. In the first group the separation of the pelvic connective tissue and the extensive wound results in the forming of the best culture-medium for infectious organisms, and that infection takes place either through faulty technic, infection from without, or through intestinal bacteria the result of injury to the intestine. He says that it is doubtful whether drainage does good in these cases—that the resulting exudate is quite as readily absorbed and eliminated by nature. As regards the second group of cases, he refers to the statistics of Zweifel of 103 adnexa operations, with 1 death, where the rubber drainage-tube was employed, but says it proves nothing. The method of Schauta, Wertheim, and Fritsch (the microscopic examination of pus during operation) he believes has the correct object, but is not positive; that the organisms may not be virulent, they may be few in number and not found, and a certain number of cases are thus unnecessarily drained. The use of drainage complicates the operation, often causing suppuration in the abdominal wound, fistula, and hernia. Finally, he concludes that *the results in complicated abdominal section are only rarely improved by the use of drainage, and that in the greater number of cases in which it is used it is not essential.* If virulent organisms are present, it can scarcely save life; if the virulence is extinct, it is not necessary. When in the removal of a noninfectious new growth the pelvic connective tissue is separated, drainage is not only unneces-

[1] Monatsh. f. Geburtsh. u. Gynäk., Supplement to Bd. ii., 1895.

sary, but often does harm. When there is a closed-off, acute inflammatory process in a tumor in the peritoneal cavity, and in its removal pus escapes into the peritoneal cavity, infection is to be feared. Particular caution should be taken that the least amount of the peritoneum is infected, and the material should be carefully removed with the sponge. The use of the iodoform-gauze tampon does not physically or chemically influence the result. The opening of acute inflammatory connective tissue in adnexa operations is very dangerous. Whether drainage can save the patient's life is questionable. In such cases he believes complete hysterectomy gives the best results. In adnexa operations he advises that the operation be performed 6 months after the last exacerbation. In cases in which the pelvic connective tissue is widely separated in the removal of a tumor (hematoma of the broad ligament) drainage is not necessary. In very difficult operations, where the pelvic connective tissue is widely separated and the case is septic, the best results are gained by complete hysterectomy and drainage with iodoform-gauze through the vagina.

Conservative Pelvic Surgery.—The adherents of the conservative methods of pelvic surgery continue to report favorable results after the operations. In 30% of his cases Delange[1] states that pregnancy subsequently occurred. Donnef[2] thinks that resection or ignipuncture is indicated in the case of every young woman who presents evidences of chronic oophoritis associated with a healthy condition of the uterus and tubes. When the uterus is diseased or the patient is near the climacteric, hysterectomy is preferable. Mathaei[3] recommends resection of the ovary in all cases of ovariotomy in which the opposite ovary contains retention-cysts too large or too numerous to be treated by ignipuncture, or even when a small dermoid cyst is present not involving the entire ovary. Exceptionally, healthy stroma may be preserved in the case of a small proliferating glandular cystoma. If the patient have passed the climacteric or if there be a suspicion of malignancy, the ovary should be entirely removed. Mathaei reports 6 cases of ovariotomy with resection of the opposite ovary, 5 of the patients subsequently conceiving and bearing living children. Gersuny[4] has successfully incised a tube-sac upon the surface toward the ovary, and into this opening has introduced the ovary, which was held in place by 6 fine interrupted sutures; a normal pregnancy followed within a few months. Nothing is said as to the symptomatic cure of the case. Henrotin[5] for the past 2 or 3 years has been in the habit of making an incision behind the uterus and digitally exploring the pelvis in all cases in which the disease-process has extended beyond the cavity of the uterus. He has done this 27 times with success. He makes his incision moderately circular, close to or rather slightly on the posterior surface of the cervix, and dissects back the vaginal mucosa through the cellular tissue to a point beyond which the wounding of the uterine artery seems improbable. Any pus that may be present is evacuated, and the abscess-cavity then

explored for additional pus-collections in the neighborhood. The finger only is used for this purpose. A gauze-packing is then introduced and retained for from 3 to 5 days.

Complications during and after Abdominal Section.—1. *Peritoneal Adhesions.*—Tappey,[1] quoting Riedel of Jena, mentions the following causes of adhesion in the abdominal cavity: Contusion of the abdomen; ulcer of the stomach; inflammation about the gall-bladder and ascending colon; conjoined inflammation of the gall-bladder and vermiform appendix; inflammation of the vermiform appendix alone; inflammatory processes in the colon; and lipomata that have become detached from their pedicles within the peritoneal cavity. In addition to the foregoing, adhesions are found in the pelvic cavity caused by inflammation of the ovaries or tubes, or both; inflammation of the uterus; inflammation of and about the rectum; and inflammation of the bladder. He further states that abdominal surgery has well established the fact that many of the pains, vague, uncomfortable feelings, and so-called dyspepsias are caused by adhesions of various organs in the abdominal and pelvic cavities. Bryon Robinson[2] believes that peritoneal adhesions are quite abundant after abdominal section. In 200 autopsies made by him he states the percentages of adhesions in the regions which he terms major regions of peritonitis as follows: (*a*) In the mesosigmoid, 80%; (*b*) In the cecoappendicular apparatus, 72%; (*c*) In the pelvis, 75%; (*d*) Around the gall-bladder, 65%. Peritoneal adhesions indicate section only when they produce definite symptoms. An operation is seldom required when the adhesions surround solid or fixed organs, but the peritonitic adhesions in the pelvis that demand operation are those involving loops of small intestines, sigmoid, bladder, or Fallopian tubes.

2. *Intestinal Obstruction.*—Rosner[3] regards intestinal obstruction after abdominal section as one of the most dangerous and least avoidable of all the complications. He claims to have greatly lessened the danger of this complication by means of a sterile sodium salt-solution (calcium sodium carbonate, 2.50 parts; sodium chlorid, 7.50 parts; water, 1000 parts). Under its use even mild laxatives were not required, the patient having natural passages; also vomiting, pain, meteorism, and other symptoms were usually absent or but slightly marked.

3. *Embolism.*—Baldy[4] regards embolism after abdominal section as a complication of great consequence, secondary only to septic peritonitis and hemorrhage in importance. Most commonly the left leg is affected. The attack begins, as a rule, about the end of the third week after the operation, at a time when the patient is in apparently perfect health and about to leave her bed. Baldy thinks that the complication is not a septic one, nor does it follow any particular lesion or operation. He reports 3 deaths from this cause, and Frederick[5] 1 death.

[3] Therap. Woch., June 2, 1895. [4] Am. Gyn. and Obst. Jour., Mar., 1896.
[5] Buffalo Med. Jour., Aug., 1895.

4. *Pelvic Hematoma.*—Schramm[1] reports a case of pelvic hematoma after oophorectomy. He refers to the hemorrhage that occurs 2 or 3 days after the removal of the uterine appendages as a possible cause of infiltration of blood in the broad ligaments. He condemns the theory of Olshausen, that it is the result of the establishment of collateral circulation after the removal of ovarian tumors, for he has seen it occur most frequently after simple oophorectomy. Hemorrhage occurring in the extraperitoneal cellular tissue he believes must be very rare, since not a single case can be found reported in literature.

5. *Ventral Hernia.*—From an observation of 1000 cases of abdominal section Winter[2] finds that nearly one-third of all the cases suffer from a ventral hernia, although in some cases the hernia does not develop for 1 or 2 years after the operation. In Olshausen's clinic it has been found that the best results are obtained by suturing the abdominal walls by three tiers of sutures—one for the peritoneum, one for the fascia, and one for the skin. In 212 cases sutured by this method only 12 have had hernia.

6. *Fistula.*—Polak[3] reports a case of uteroabdominal fistula after abdominal section for right multilocular ovarian cystoma, which was demonstrated with methylene blue and by direct exploration of the right ureter. Spontaneous closure occurred 40 days after the primary operation. Cestan[4] states that ureterovaginal fistulæ are most frequently produced during the first stage of vaginal hysterectomy. In the treatment of this condition he prefers Bazy's operation.

7. *Emphysema of the Abdominal Wall.*—Meinert,[5] at the meeting on Oct. 14 of the Dresden Gynecological Society, referred to 8 cases reported in the literature (Madlener, Graefe, Winter, and Casperson) of emphysema of the abdominal wall observed after abdominal section, and records an additional case. In the writer's case this condition of artificial emphysema of the abdominal wall appeared after the operation of abdominal hysterectomy for the removal of a fibroid tumor. As in all other cases reported, the Trendelenburg posture had been employed during the operation. In the discussion following Leopold stated that he had seen 6 cases of emphysema of the abdominal wall, and that in every case the Trendelenburg posture had been employed. He has noticed that the emphysema occurred between the peritoneum and muscle (that the peritoneum was sometimes easily separated from the muscle, particularly when there had been considerable manipulation in the peritoneal cavity) and in the subcutaneous areolar tissue. He also believes that it is not harmless, but that it increases the rapidity of the pulse, causes considerable pain, and makes the patient restless. It also may extend into the inguinal region or even, as in 1 case, to the axilla. In those cases in which the disease tends to extend Leopold advises early incision. Brosin said that he had seen 3 or 4 cases under the same conditions as those reported. He observed that healing was always disturbed, and believes there is another form of emphysema due to the forma-

tion of gas by bacteria. This last was not sanctioned by Meinert and Leopold. Osterloh stated that this emphysema could be avoided by placing the patient in the horizontal position before closing the abdomen. The greater amount of air would thus be expelled.

After-treatment of Abdominal Section.—[Acetanilid is coming largely into use as a dressing after abdominal section, as well as for wounds of every description.] Francis L. and John R. Haynes[1] speak enthusiastically of the results obtained. The preparations of the drug that are employed are as follows: 1. *Acetanilid glycerol*, made by mixing 40 parts of cold sterilized glycerol with 1 part of acetanilid powder (not crystals), and rubbing thoroughly with a pestle. No heat must be used in making this glycerol, lest crystals should deposit. Should suppuration persist, notwithstanding the use of the glycerol, it may be increased in strength by the gradual addition of a solution of acetanilid in alcohol, 20 gr. to the ounce, commencing by adding 1 oz. of this alcoholic solution to 4 oz. of glycerol. 2. *Boric acetanilid*, made by mixing thoroughly powdered boric acid 6 parts with powdered acetanilid 1 part. It is stored in glass bottles holding 70 gr. Not more than one of these bottles is to be emptied, in the case of an adult patient, in 24 hours. It is dusted over wounds so as to form a thin layer. If used in large quantities it cakes and produces irritation of the skin, and sometimes superficial ulceration. If for any reason it is used in large quantities, it must be covered with gauze and with paraffin paper to prevent caking. 3. *Acetanilid vaselin*, made by rubbing powdered acetanilid 1 part with "cream-white vaselin" 20 parts. It is very useful as an application to cracked nipples and superficial lesions generally. Using precaution against poisoning, the strength of this ointment may be increased. 4. *Acetanilid gauze*, made by dusting 17.5 parts of boric acetanilid over 82.5 parts of sterilized gauze (making a 2.5% acetanilid gauze) in the form of hemmed strips 10 ft. long and 1 in. broad. These strips are then rolled like ordinary roller bandages, stored in sterilized air-tight jars, and used in place of iodoform-gauze. 5. *Acetanilid oil* has been used in a few cases as an injection in the strength of 1 : 40. Reichel[2] considers the question as to whether it is advisable after the operation of abdominal section to stimulate or depress *peristalsis*, and, further, what influence treatment has upon intestinal paresis or ileus. He believes that, regardless of the fact that the operation may be aseptic, there may be a migration of bacteria, that these bacteria may be distributed over the entire peritoneum, and may possibly be quickly absorbed and destroyed, but that, on the other hand, diffuse or circumscribed purulent peritonitis may result. Also, that if this purulent peritonitis is isolated the prognosis is always better. Granted that this is true, he concludes that in cases of intestinal resection and those sections in which a portion of infected material is allowed to remain in the abdominal cavity, the arrest of peristalsis is not advisable—that the administration of opium does harm. He advises that from the day of operation peristalsis should be slightly stimulated by the administration of small doses of saline water, and the bowels should be

[1] Am. Jour. Gyn., Apr., 1896.

[2] Arch. f. klin. Chir., Bd. 50, H. 2, 1895.

opened on the second or third day. Should the symptoms of subacute intestinal paresis or ileus appear, probably due to intestinal adhesions, no food and only a small amount of water should be given; also that the stomach should be repeatedly washed out and opium given in suppository. Saline cathartics are now contraindicated. If the patient's condition improve, an enema of water containing glycerin should be administered. If, after 24 hours, or at the latest 48 hours, the patient's condition have not improved, the abdomen should be reopened. When the trouble is thought to be due to mechanical occlusion of the intestine, as when there is advanced peritonitis, purgation is strongly contraindicated. Reichel believes that simple mechanic occlusion is rare; that the greater number of cases are due to paresis of the intestinal muscle-wall where the intestine is bent upon itself or looped; that this paresis and the stenosis is increased and the bowel distended when artificial peristalsis is induced. Therefore this condition is best treated by keeping the intestinal tract at rest. The abdomen should be reopened when there is sepsis and when the symptoms point toward mechanic obstruction.

To overcome the *intense thirst* that follows abdominal section Humiston[1] for 3 days prior to operation orders the patient to drink 1 pint of hot water an hour before each meal and on retiring, making 2 quarts of water each 24 hours, the last pint to be taken 3 hours before the time set for operation. No thirst follows the operation, the tongue is moist, and the renal function active. The water supplies the loss occasioned by the free catharsis.

The successful results obtained from the use of thyroid extract in the treatment of diseases dependent upon removal of the function of the thyroid gland has led Mainzer[2] to employ a preparation of the ovaries of cows and calves in the treatment of the phenomena that often appear at the menopause or in the sequence of removal of the ovaries for any purpose. In a given case the attendant symptoms, fulness of the head, palpitation of the heart, vertigo, flushing, and sweating, were relieved by the use of such a preparation, the use of which was at the same time unattended with any unpleasant effect.

Hydrosalpinx.—Hydrosalpinx is a collection of serous fluid in a Fallopian tube, rarely becoming larger than a child's head. T. S. Cullen[3] divides it into four varieties: 1. *Hydrosalpinx simplex.* Here the tube is usually normal in size at the uterine end, but dilated toward the fimbriated extremity, appearing convoluted, and, curving backward and inward, usually falls into the pouch of Douglas. The walls are generally thin and covered by adhesions, and may contain areas of calcification; the muscular coat is normal or atrophic. A calculus may exist in the lumen of the tube. 2. *Hydrops tubæ profluens*, a rare variety, and differing from the foregoing in that the uterine end of the tube is patent at times, Hennig's sphincter probably occluding it in the intervals. 3. *Hydrosalpinx follicularis.* This resembles hydrosalpinx simplex externally, but the mucosa appears honeycombed, and no central lumen may be seen.

[1] Am. Jour. Obst., July, 1895. [2] Deutsch. med. Woch., 1896, No. 12, p. 188.
[3] Johns Hopkins Hosp. Rep., vol. iv., Nos. 7, 8.

4. *Tuboovarian cyst*, a dilated Fallopian tube resembling a simple hydrosalpinx and communicating with an ovarian cyst.

Hydrosalpinx is probably due to infection during childbirth or miscarriage, or to gonorrhea. In hydrops tubæ profluens Hennig's sphincter probably closes temporarily the uterine end of the tube. Hydrosalpinx follicularis is usually preceded by salpingitis, which causes adhesions of the mucosa, and thus forms the alveoli, which become distended by fluid. In tuboovarian cysts the tube becomes adherent to a small ovarian cyst, and their growth causes, by pressure, absorption of the intervening tissue. The normal secretion of a tube can produce hydrosalpinx if both ends be occluded. There are no fixed symptoms, but usually sharp, dull, intermittent or continuous pain in the ovarian region, at times radiating down to the knees, and most severe at the menstrual periods. Defecation and coition may cause pain. The influence on menstruation is doubtful. The disease causes a liability to miscarriage, and sterility is often produced. Diagnosis is aided by feeling through the vagina a cordlike mass running from the uterus and suddenly dilating and giving a sense of elasticity. A positive diagnosis can rarely be made, except in hydrops tubæ profluens. We must differentiate subperitoneal myomata, pyosalpinx, tubal pregnancy, ovarian tumors, and prolapsed and distended sigmoid flexure. The prognosis is good. For treatment the tube and ovary must be shelled out of their adhesions and removed; if they are densely adherent, the uterine cornu is resected to obtain a starting-point.

Tuberculosis of the Fallopian Tubes.—[It is now very conclusively demonstrated that tuberculous inflammation of the Fallopian tubes is much more frequent than has been supposed.] In a second paper on this subject Penrose and Beyea[1] report a series of 27 cases of pelvic inflammatory disease upon which operations were performed, in which 4 cases of tuberculosis of the tubes were found, giving a percentage of 14.8. Orthmann[2] states that primary tubal tuberculosis occurs in 18% of all cases of tuberculosis of the female genital tract, the ovaries and tubes being the portions most frequently involved. He reports 2 cases of primary tuberculosis of the tubes, and further states that secondary infection from the tubes takes place most frequently in the peritoneum, next in the uterus, and then in the ovary. Ascites occurs relatively seldom—in 15% of the cases.

Van der Veer[3] emphasizes the importance of cervical laceration as a point of development of tuberculosis. He also states that tuberculosis of the female genitals is of two varieties—miliary tuberculosis, and chronic, diffuse, fibroid tuberculosis, the caseous form of the disease.

Maas[4] calls attention to the rare occurrence of genital tuberculosis in children in comparison with its frequent appearance in other regions. In a careful search through the literature he was able to find only 7 cases, to which he adds an eighth. In the autopsy upon a girl 5 years old, who died of general tuberculosis, he found tuberculous ulceration of the mucosa of the uterus and

[2] Internat. Med. Mag., Jan., 1896.
[3] Ibid., June, 1896.
[4] Arch. f. Gynäk., 1896, Bd. li. H. 2.

tubes. The muscular wall of the latter was filled with tuberculous nodules, but that of the uterus was not affected. The ovaries were normal. There seemed to be no doubt that the internal genitals were the original seat of the trouble. The cause of the infection was most obscure. It seemed improbable that bacilli could enter the vagina, as the hymen was intact and the ordinary causes (coitus, unclean instruments, etc.) could be positively excluded. Moreover, the vagina was healthy. The presence of a line of old fibrous tubercles along adhesions extending inward from the umbilicus to the parietal peritoneum led the writer to infer that the infection entered through the navel—a fact of considerable interest to the obstetrician.

Pneumoperitoneum.—Gas in the abdominal cavity is a matter of considerable interest, and Ross[1] has presented an exhaustive paper upon the subject. He classifies pneumoperitoneum or tympanites as follows: 1. Tympanites intra intestina. 2. Tympanites extra intestina: A. Traumatic: *a*. From without; *b*, from within; B. Nontraumatic or spontaneous: *a*. Without liquid, gas odorless; *b*, ascites, and gas odorless or fetid; *c*, pus and fetid gas. 3. Tympanites intra et extra intestina. The first variety is frequently met with as a consequence of inflammation of the intestines themselves or of their serous coats; from obstruction of the lumen of the bowel from any cause; or as a result of the action of certain poisons, as atropin. The entrance of gas from without the abdomen is rare, but there are several cases on record of the second variety of traumatic tympanites following perforation of round ulcers, of dysenteric ulcers, of typhoid ulcers, of secondary ulcers due to stricture, of ulcer of the cecum, from perforation of the appendix, from malignant sarcomatous ulcers, and from rupture of the intestines from a blow on the abdomen. Ross has found records of 5 cases of spontaneous or nontraumatic tympanites extra intestina in which no fluid was present and in which the gas was odorless. As regards treatment, he believes that in all cases of marked pneumoperitoneum exploratory abdominal incision is justifiable.

DISEASES OF THE OVARIES.

Cystomata.—Cases of more than ordinary interest are reported by Stocker,[2] Peters,[3] Cripps,[4] Croom,[5] Jahreiss,[6] Travers,[7] Doege,[8] Thomson,[9] Seguen,[10] and Cullingworth.[11] The latter successfully removed an ovarian cyst weighing over 80 pounds from a girl 16 years of age. Jahreiss records an acute torsion of an ovarian pedicle in 4 cases relieved by ovariotomy, while Travers has successfully removed an ovarian tumor showing axial rotation and associated with a retroperitoneal cyst of the same side from a woman 51 years of age. Doege's case was one of parovarian cyst complicated by the passage of renal calculi,

the case simulating and being diagnosed as one of ectopic gestation; a successful operation was performed. Croom records an interesting case of glycosuria complicating a colloid cyst of each ovary, but unassociated with the usual diabetic symptoms. The two tumors weighed 56½ pounds. In 6 weeks' time all traces of sugar were gone. Peters reports a case of ileus due to simple pressure of an ovarian cyst. In the other 12 reported cases the obstruction was due to torsion of the pedicle. The patient, aged 60 years, had had an abdominal tumor for 10 years, with symptoms of intestinal obstruction of a year's standing. Peters was called to see her on account of a sudden attack of abdominal pain. She had had no movement of the bowels for 4 days; two small stools followed the administration of high enemata. On examination the abdomen was found to be tympanitic, a cystic tumor as large as a man's head being detected, which filled the pelvis. There was an umbilical hernia the size of the fist, which contained omentum, but no intestine. The diagnosis of ovarian tumor with torsion of the pedicle was made, but on opening the abdomen the obstruction was found to be due to direct pressure of an adherent papillomatous cyst upon the cecum. The patient had a spontaneous evacuation of the bowels 2 hours after the operation, and made a good recovery. Stocker's case was one of a large right ovarian cyst in which an acute torsion occurred, the pedicle being twisted 4 times. On the second day the patient became restless, then sleepy, and on the following day comatose. Urine was secreted sparsely, and contained much albumin, and later leucin and tyrosin crystals. The conjunctivæ at length became distinctly yellow; the abdomen never felt tense; and on the fourth day the patient died. The autopsy revealed an acute yellow atrophy of the liver, that organ being small, flaccid, and intensely yellow, with minute ecchymoses sparingly spread over its surface. There was no trace of peritonitis, and the pedicle was healthy. Stocker believes that the liver disease began before the ovariotomy, and was due to the torsion of the pedicle, necrosed products being absorbed into the circulation. Cripps reports 13 cases of *strangulated ovarian cysts* encountered in 3 years' time in the women's ward at St. Bartholomew's Hospital, out of a total of a little over 100 ovariotomies during that period. The symptoms of strangulated ovarian cyst are very characteristic, if the twist occurs suddenly. The woman is suddenly seized with severe abdominal pain, sometimes sufficient to make her feel faint, and generally followed by some vomiting; there is a diffuse tenderness over the whole abdomen, and coincidentally with this attack the tumor seems to swell up and become harder. On abdominal examination the tumor may be felt of a globular outline, but generally of not a very large size. It is tender on pressure, and has a somewhat firmer feel than the majority of ovarian cysts. It can be moved from side to side, and occasionally some creaking can be heard and felt, due to the rubbing of inflamed peritoneal surfaces. The general condition is one of distress; the pulse is rapid, and the temperature more often raised than not, though the thermometer is not a reliable guide. If the temperature is elevated, the prognosis is far more favorable than when the same symptoms are present with a normal or subnormal temperature.

Symptoms resembling those of a twisted cyst may be due to a simple inflamed cyst, a ruptured cyst, an extrauterine fetation, or a hematocele. The outline of a twisted cyst is well defined; it feels firm and the tumor is somewhat larger than previously, while in a ruptured cyst the outline of the tumor becomes indistinct, and the cyst feels flaccid, is smaller, or even disappears, while there is dulness in the flanks from gravitation of the extravasated contents to these regions. If a twisted cyst is not diagnosed early, the symptoms may rapidly pass on into those of acute peritonitis. The treatment is immediate operation.

Mangold[1] distinguishes 2 forms of *infection of ovarian cystomata*—namely, saprophytic and septic. The former causes suppuration of the cyst-contents, and is recognized by the hectic character of the fever, slight pain and general disturbance, the absence of evidences of peritonitis, and the presence of gas in the upper portion of the cyst. The prognosis is good. Great care should be exercised to remove the cyst intact or, in the event of rupture, to protect the peritoneal cavity and wound. Septic infection is due to the presence in the cyst-contents of pyogenic cocci, gonococci, and the bacilli of typhoid and tuberculosis, and the colon bacilli. Chills, fever, rapid pulse, peritonitis, and profound general disturbance indicate the serious nature of the process. The prognosis is less favorable than in the former case. Bacteria may enter a cyst by direct implantation through the venous circulation (especially from a septic puerperal uterus), through the lymphatics by extension from an infectious peritonitis, and from the gut when the latter is adherent to the cyst. Puncture, incision and drainage, coitus during menstruation or the puerperium, infectious diseases (typhoid and malaria), gonorrhea, salpingitis, and peritoneal tuberculosis are all etiologic factors. Spontaneous suppuration of dermoids is due to the setting free of a pyogenic irritating substance from the cyst-contents.

Pfannenstiel[2] presents an elaborate paper on *papillary growths of the ovary*. He remarks that while papillary parovarian cysts and hydrops folliculi are quite innocent, ovarian sarcoma and carcinoma of the papillary variety are extremely malignant. Between these extremes stands papillary adenoma, the prognosis of which is favorable, provided that the entire tumor be removed and there are no metastases on the peritoneum. Even when portions of the tumor are left behind, the progress of the case to a fatal termination is slow. On the other hand, a considerable proportion of these papillary cysts are primarily carcinomatous. Malignant degeneration of a true adenopapilloma is by no means so common as has been stated. Bland Sutton[3] has ascertained that simple cysts of the oophoron grow with far greater rapidity than the adenomata and dermoids. He further states that a dermoid may arise in the ovary and attain dangerous proportions in an adult woman within the space of 3 years, and concludes that ovarian dermoids are not due to inclusion of surface epiblast.

As a contribution to the subject of the *hereditary transmission* of ovarian cystomata Löhlein[4] reports the cases of 3 sisters, all of whom presented cysts of both ovaries, which were removed by operation. Olshausen, who has

[1] Centralbl. f. Gynäk., No. 40, 1895. [2] Arch. f. Gynäk., Bd. xlviii. H. 3, 1895.
[3] Clin. Jour., June 19, 1895. [4] Monatsh. f. Geburtsh. u. Gynäk., 1896, B. iii. H. 2, p. 91.

probably enjoyed the largest experience of similar nature, has reported the cases of 3 sets each of 2 sisters, in which he has operated for the removal of ovarian cysts upon one side.

The fluid contained in ovarian cysts has been suggested by McCann[1] as a medium for the cultivation of the gonococcus and other microorganisms. It is necessary for this purpose to obtain specimens of fluids that are fairly clear, but at the same time contamination with blood should not prevent the fluid being used. The trocar used to tap the cyst should be sterilized by boiling. The first portion of the ovarian fluid being rejected, the remainder is collected in tall cylindric glass jars, known to bacteriologists as "blood-jars." These glass jars, which are provided with an accurately fitting glass stopper, are first cleansed with a 1% solution of mercuric chlorid, followed by absolute alcohol. The stopper should be smeared with vaselin containing mercuric chlorid, to prevent it becoming fixed and to exclude atmospheric dust from the jar and its contents. The fluid collected in the jars should be allowed to stand for 24 hours in a cool place, when any sediment will have been deposited at the bottom. It will be well to boil a portion of the fluid in a test-tube in order to determine the proportion of albumin. If the fluid turns solid on boiling, it will prove a good medium. As the proportion of albumin in cystic contents varies considerably, it is specially needful to adopt this precaution. The fluid having been cooled as described, the supernatant portion is removed by means of a sterilized pipet and transferred to sterilized test-tubes provided with sterilized cotton-wool stoppers. The test-tubes are then placed in a slanting position in an incubator, which should be kept at a temperature of from 66° to 68° C. for 4 hours. After this time the fluid is of gelatinous consistence and good transparency. It will be found that the gonococcus grows better when little mounds of pus are placed on the medium instead of streaks or punctures. The inoculated test-tubes should be placed in a glass vessel half filled with distilled water and provided with a well-fitting glass plate. The object of the distilled water is to moisten the air in the vessel, so that the surface of the medium is kept in a similar condition. The glass vessel containing the test-tubes should be placed in an incubator kept at from 30° to 34° C. The cultures thus obtained after 24 to 48 hours are very thin, scarcely visible, grayish-yellow by reflected light, the surface smooth and moist, the edges diffusing into the surrounding medium, which is not liquefied. [The main objection to the use of this substance as a culture-medium is the difficulty of securing a sufficient quantity of the fluid. Aside from this it would appear to be a very desirable and appropriate substance for the purpose.]

Cases of *ovarian dermoid* are reported by Lannelongue and Faguet,[2] Ullmann,[3] Richardson,[4] Forbes and Reid,[5] and Schulze.[6] The latter describes an operation for the removal of 2 retrorectal dermoid cysts extending from a point just above the sphincter ani as high as the pelvic diaphragm. He believes

[6] Deutsch. med. Woch., No. 22, 1895.

that these tumors originate not from the ovary, but from the spinal canal or external skin, and advises their removal through an incision in the perineum, the ischiorectal fossa being opened by a cut extending from the posterior third of the right labium majus to a point 1 in. above the anus; the levator ani is separated in the direction of its fibers. Forbes and Reid's case was an enormous dermoid cyst of the left ovary, the removal of which was followed by the development of a spindle-celled sarcoma, with ultimate death of the patient. Lannelongue and Faguet report a case of dermoid cyst of the right ovary associated with an endothelioma, the latter being a rare variety of tumor first described by Eckhardt and Pomorski. The tumor in Ullmann's case weighed 35 lb. and contained 13½ pints of a greasy fluid.

Solid Ovarian Tumors.—Cases are reported by von Kahlden,[1] Hirst,[2] Skene,[3] Page,[4] and Alfred J. Smith.[5] Hirst's case was one of a large myoma of the ovarian ligament, one of the rarest of all pelvic tumors. It weighed 3 lb. and measured 15 in. in the smallest circumference; histologically, it was of the nature of a leiomyoma. Skene reports a case of ovarian cystomata and carcinomata involving both ovaries; a successful operation was performed. Smith's patient suffered from a myosarcoma of the left ovary associated with an enormous quantity of ascites, while Page's patient, a child of 6 years, presented a fibrosarcoma of the left ovary weighing 3¾ lb. This is the youngest patient who has ever successfully undergone an operation of this kind. Von Kahlden describes a peculiar form of carcinoma of the ovary removed from a young girl. The growth did not arise directly from the epithelium of the follicles, but passed through a stage that must be looked upon as adenoma of the Graafian follicles—a condition hitherto unknown.

Cullen[6] records a unique case of adenomyoma of the round ligament occurring in a woman 37 years of age. Histologically, the growth was composed of nonstriped muscular fibers, with glands traversing the nodule in all directions (see Figs. 117, 118). The tumor was of slow growth and evidently benign.

FIG. 117.—Cullen's case of adenomyoma of the round ligament, natural size (Johns Hopkins Hosp. Bull., May-June, 1896).

Hernia of the Ovaries.—Cases have been noted by Cousins[7] and Lockwood.[8] Lockwood's patient was an infant, in whom the ovary was found in the right inguinal region with torsion of its pedicle. Cousins reports a case of acquired inguinal ovarian hernia on the right side, and also an exceedingly rare case of rup-

ture of Douglas's pouch, with protrusion of the uterine appendages through the vulvar orifice, in a melancholic woman 50 years of age (see Fig. 119).

FIG. 118.—A portion of the adenomyoma enlarged 16 times (Johns Hopkins Hosp. Bull., May–June, 1896).

Prolapse of the Ovaries.—Sänger[1] differentiates 2 classes of descent of the ovaries. In *descensus lateralis* the ovary remains at the side of the uterus, while in *descensus posticus* or retrouterine it is found behind the uterus and over the fornix. As etiologic factors for this descent, injuries, the puer-

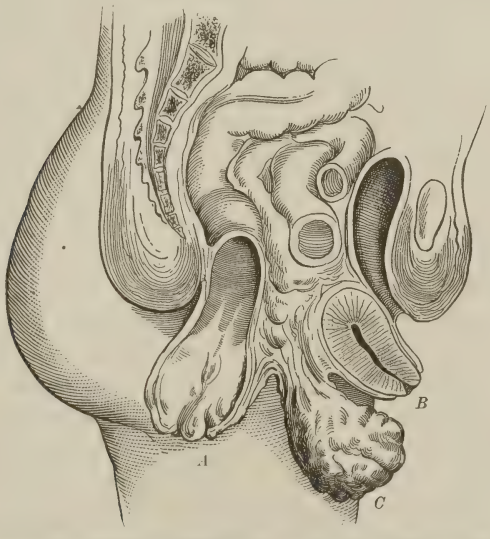

FIG. 119.—Diagram showing the protrusion of the appendages externally: *A*, rectal prolapse; *B*, uterus; *C*, uterine appendages (Brit. Med. Jour., July 27, 1895).

perium, malposition of the uterus, the removal of tumors, and enlargement and abnormal mobility of the ovaries are mentioned; to these must also be added the result of vaginal celiotomy. The treatment may be either medical or operative. To the operative methods Sänger adds the artificial fixation of

[1] Centralbl. f. Gynäk., No. 9, 1896.

the movable ovary, the ovary being attached to the side of the pelvis; this operation is termed "pelvifixura ovariosum." He reports 2 successful cases.

Abscess.—Langer [1] reports 5 cases of isolated abscess of the corpus luteum operated upon at the Prague Clinic within a month. Microscopic examination proved these to have arisen from suppuration of preexisting corpora lutea, as shown by the presence of the characteristic cells. These abscesses are to be distinguished from those that develop from a Graafian follicle or corpus luteum cyst. Etheridge[2] reports 3 cases of ovarian abscesses produced by the *micrococcus lanceolatus* (*diplococcus pneumoniæ*); hitherto there have been no such cases reported. The pus was loaded with the micrococci.

Anomalies.—According to Otto Engström[3] of Helsingfors, there are two distinct kinds of supernumerary ovaries. One is due to anomaly of development, in which three ovaries are formed instead of two. These cases are rare, and their existence was doubted by Rokitansky, Klob, and others. Winckel[4] reported the first case of the kind in 1881, in which ovaries on either side were normal, but on the right side and in front of the uterus was a supernumerary ovary larger than either of the others, and attached to the uterus by a ligament originating from the right round ligament. The ovary was situated in a fold of peritoneum connected with the bladder. Other cases have since been observed by different writers. Besides cases of this kind, there are supernumerary ovaries due to division of a normal ovary by inflammatory processes and the formation of bands. Engström presents photographs of a case of this kind. The patient was 55 years old and was operated upon for a myoma. She had suffered many times from peritonitis. On the right side was found an ovary nearly divided into two parts by the presence of bands. The part near the uterus appeared nearly normal, while the distal half was badly degenerated and contained blood-clots. The band of tissue connecting the parts together contained ovarian tissue. [We must therefore make a classification of supernumerary ovaries into congenital and acquired.]

The Ovaries in Osteomalacia.—Rossner[5] made careful examinations of the ovaries in 3 cases in which castration was performed for the cure of osteomalacia. In the cortical substance the microscope revealed hypertrophy of the vessel-walls with extensive hyaline degeneration. Curatulo and Tarulli[6] conclude that the ovaries, like other glands, have a secretion peculiar to themselves which is separated from the blood, but the chemical composition of which is not known. It possesses the property of oxidizing phosphorus-compounds or those that furnish the lime-salts of the bones; hence, after the removal of the ovaries in osteomalacia there is an increased deposit of calcium and magnesium phosphates in the bones, thus restoring the normal firmness of the latter.

PATHOLOGY.

By JOHN GUITÉRAS, M. D., and DAVID RIESMAN, M. D.,
of Philadelphia.

Resume of the Year's Progress.—All branches of pathology show evidences of progress, and, while the year has not cleared up many obscure problems, much has been accomplished to give us a better comprehension of the nature of a number of morbid processes. In the subject of hematology we would point out the researches on leukemia, which, though far from elucidating the causes of that disease, have brought to light several important facts. The nature and origin of eosinophile cells remain, however, still obscure. Pernicious anemia is probably firmly established as a hemolytic disease, with the probability that the hemolytic agent is derived from the gastrointestinal tract. Under the head of diseases of the circulatory organs the researches of Banti on the causes of loss of compensation in valvular heart-disease are given at some length, and will be found instructive. Among diseases of the nervous system the subjects of multiple sclerosis and of spastic paraplegia have been much advanced. There is increasing evidence that the latter disease has nearly always a multiple sclerosis as its anatomic basis. The question of the occurrence of hematogenous jaundice has received considerable attention, and the experiments of Auld and of Hunter will be found detailed in the section on diseases of the digestive tract. Under diseases of the respiratory tract a description of Abel's ozena-bacillus has been given, and reference is made to a number of studies on the etiology of pleurisy. Valuable papers on pneumonia are also noted. In the science of onkology the greatest interest still is centered in the causation of the malignant tumors, but we cannot say that, despite a large number of valuable researches, we feel impelled to change the opinion expressed last year on this question. It is clear, however, that the protozoan theory has fallen into desuetude. Efforts are being made, principally by the Italian school under the leadership of Sanfelice, and by a few German pathologists, to prove that blastomycetes are the cause of malignant neoplasms, but the evidence so far does not warrant a positive conclusion. Great advances have been made in bacteriology, particularly in the line of immunity. The peculiar reactions discovered by Pfeiffer between the serum of immune animals and the bacteria to which they are immune, and studied by him, Kolle, Löffler and Abel, Gruber and Dunbar, and others, are of extreme importance, and already clinicians are endeavoring to utilize these reactions for purposes of clinical diagnosis. In the subject of tuberculosis the studies of Kossel on

tuberculosis in early childhood are interesting. The specificity of the typhoid bacillus may be considered settled by the results of Pfeiffer's experiments. Elsner's method of isolating the bacillus promises to be of great value, enabling us to make an early diagnosis. The researches of Vaillard on the heredity of acquired immunity confirm the theories of Ehrlich on this subject. Progress is being made in the effort to isolate, in a solid form, the antitoxic bodies of the serum of immune animals. Antistreptococcic serum gives promise of usefulness. Diphtheria-antitoxin and diphtheria-immunity are still subjects of diligent research. In the section on technic the more important advances will be found noted. The concluding pages of the chapter on Pathology comprise references to a variety of interesting subjects not elsewhere classifiable.

To any one who follows pathologic and clinico-pathologic literature it must be evident that a revolution is silently but surely being accomplished in medical science—namely, the subordination of morphologic to chemic studies. The science of chemic pathology is increasing in strength and importance, and we hope in future pages to give due prominence to its results.

DISEASES OF THE BLOOD AND THE BLOOD-MAKING ORGANS.

Hematologic Studies.—Weiss[1] publishes the results of work extending over a number of years. The first chapter of his monograph deals with the **vanillin-reaction of the eosinophile cells.** Since the α-granules give the vanillin-reaction, they must be considered as albuminous. In another chapter Weiss points out that of all the elements of the blood the eosinophile granules are the most resistant; they even defy the action of the gastric juice. With respect to the characteristic blood-change in leukemia, the author states that it consists in a polymorphism of the white cells, in a multiplicity of sizes and forms of the cell-bodies and nuclei, and in the presence, as far as size is concerned, of all possible gradations of granule-cells. It is this polymorphism that distinguishes the blood-picture of leukemia from that of leukocytosis. In another section the blood-picture of a **lymphosarcoma of the spleen** is described. The diagnosis had wavered between tumor of the spleen and tumor of the kidney. The blood showed leukocytosis characterized by an increase of eosinophile cells and an absence of polymorphism. This led the author to diagnosticate a nonleukemic splenic tumor, and, as already indicated, the tumor was a lymphosarcoma. The bone-marrow showed the changes seen usually only in leukemia. In the author's opinion, the sarcoma directly sends cells into the blood and contributes to the leukocytosis. In the next chapter the characters of the blood of infants, both in health and suffering from various diseases, are described. With regard to **anæmia infantum pseudoleukæmica,** the author is cautious in forming a final judgment as to its independent character; he recognizes a distinct hematologic picture to which this name is applicable, but is not prepared to admit that it is a separate disease with definite clinical symptoms. With von Limbeck he believes that between

[1] Hämatologische Untersuchungen, Vienna, 1896.

anæmia infantum pseudoleukæmica and leukemia there is an intimate relation, if, indeed, the first is not a special form of the latter disease.

In the chapter entitled "**The Correlation of the Blood and Organs,**" the author takes the ground that all tissues can form leukocytes, and that these enter the blood through the lymph-paths. Neusser has already accorded to the skin a hematopoetic function; the author ascribes the same property to the bronchial and intestinal mucous membranes, and, indeed, to all tissues. The blood thus becomes the *direct representative of all the bodily organs.* The next two chapters deal with **pseudoleukemia.** Weiss excludes pseudoleukæmia lienalis and medullaris as nonexistent, and maintains that there is only a lymphatic pseudoleukemia. As lymphemia the author describes a condition in which the leukocytosis is due to a great increase in lymphocytes. Three cases are described, of which 1 was, anatomically, a myelo-lieno-lymphatic leukemia, 1 chiefly intestinal, and 1 medullary, yet all presented the same blood-changes. The relation of lymphemia to leukemia is referred to in the conclusions, which are as follows: 1. The terms lienic, myelogenic, and lymphatic leukemia should be avoided. They are applicable only to the disease of the spleen, bone-marrow, and lymph-glands as observed at the autopsy. Clinically, they are of no value, for, 2. It is not possible to infer disease of any special organ in leukemia from the blood-state. 3. There are only two forms of leukemia: (*a*) *Lymphemia:* The blood shows an increase of white cells of the type of lymphocytes; (*b*) *Leukemia proper:* The blood presents an increase of white cells, of the type of leukocytes in the wider sense—cells presenting all possible variations between the size of the nucleus and the size of the cell-body. 4. The increase of the eosinophile cells occurs generally only in leukemia proper, exceptionally in lymphemia. 5. The characteristic feature of the leukemic blood as against that in leukocytosis is the polymorphism of the white cells. This affects either the lymphocytes or the leukocytes in a wider sense. 6. Two types of leukemia may therefore be recognized from the clinical standpoint—(*a*) Leukemia of lymphocythemic type; (*b*) Leukemia of leukocythemic type. 7. It is impossible from a microscopic study of the organs to draw any inferences concerning the differences between the two diseases. 8. The conception of "acute leukemia" should, if possible, be narrowed. The leukemias of lymphocythemic origin are not always acute, but may run a chronic course.

The Myelocyte of Ehrlich.—Cabot[1] has made a study of the distinguishing characters of the myelocytes. The criteria formerly employed—size, shape, and number and shape of nuclei—are not of much value. 1. The staining characters of the myelocyte-nucleus (pale and even) are generally to be contrasted with those of the cell most resembling it (the so-called "multinuclear" cell), the nucleus of which stains darkly and unevenly. But this criterion will not always serve. 2. The shape of the myelocyte-nucleus (round or oval) is generally to be contrasted with that of the multinuclear cell (twisted, broken), and when this differentiating mark is not present there is, usually, 3. The comparative juxtaposition of the nucleus of the myelocytes to

[1] Boston M. and S. Jour., Jan. 2, 1896.

the surface of the cell as a guide in distinguishing them from the "multinuclear" cells, the nucleus of which is more centrally placed, or, if it approaches the surface, quickly leaves it again. But even with these criteria it becomes at times difficult to say whether certain cells are myelocytes or multinuclear cells. The author then suggests the following definition: "A myelocyte is a spheric, neutrophilic cell, varying in diameter from 7 μ to 20 μ or more, and characterized by the presence of one (or rarely two) nuclei which [with Biondi's stain] stain faintly and evenly, with a purplish or greenish-blue color, are generally round or oval, often vacuolated, and are in close relation to the surface of the cell for a comparatively large portion of their extent." He concludes as follows: 1. The definition of myelocyte must be enlarged so as to include cells of all sizes from 7.5 μ upward. 2. The percentage of myelocytes in leukemia is much larger than that generally given in text-books; 25% is a small number. 3. Small percentages of myelocytes are the rule in pernicious anemia, common in malignant diseases of cachectic type, and not uncommon in a variety of other conditions.

Eosinophile Cells.—Vorbach[1] examined 20 cases of gonorrhea, and comes to the following conclusions: There is no corresponding relation between the number of eosinophile cells in the blood and **in the gonorrheal discharge.** The appearance of eosinophile cells in the discharge depends entirely on the condition of the urethral mucous membrane. The eosinophile cells in the gonorrheal discharge have no diagnostic significance. Examination of the blood in 18 healthy individuals gave a proportion of eosinophile cells to other leukocytes of 0.5–11.5%, the mean being 4.22%. Grouven[2] found that **the respiratory mucous membrane** in bronchitis, corresponding to the sputum, contained eosinophile cells, although in limited numbers. In tuberculosis eosinophile cells were not found in the mucosa, as also not in the sputum. The normal mucous membrane of the respiratory tract shows absolutely no eosinophile cells, while the intestinal mucosa does. It was not possible to extend the investigations to asthma and croupous pneumonia, as no cases came to autopsy at the time. Stutz[3] found few or no eosinophile cells in the normal mucous membrane **of the stomach;** in all states of irritation or inflammation the cells are increased in number, but only moderately. They are very abundant in carcinoma. In the intestinal mucosa eosinophile cells are, as a rule, present in large numbers. In diseased states the number is variable—in specific suppurative processes they are sparse, especially in tuberculosis, typhoid, and diphtheric ulceration. The appearance of eosinophile cells is probably connected with a certain activity of the mucosa, as, *e. g.*, during digestion. A chemic or slight pathologic irritant produces the

[3] Ueber eosinophile Zellen in der Schleimhaut des Darmkanals, Bonn, 1895, Inaug. Dissert.; ref. in Centralbl. f. Allg. Path. u. Pathol. Anat., July 15, 1896.

same effect, the number of eosinophile cells decreasing with the intensity of the irritant. The author believes these cells are formed in the mucous membrane, although no positive proof is brought forward. He thinks that the ordinary leukocytes in the mucosa of the intestine become eosinophile cells, and that these pass in part externally, in part into the blood.

Local "Eosinophilia" in Carcinoma; the Nature of Eosinophile Cells.—Przewoski[1] observed a marked accumulation of eosinophile cells in 4 cases of carcinoma of the cervix uteri. In discussing this phenomenon the author enters into a consideration of the nature of eosinophile cells. He holds that the eosinophile granules are albuminoid in nature and contain iron. The granules are the secretory product of the protoplasm of certain leukocytes. The cells originate in the blood-forming organs, particularly the bone-marrow, and their function, the author believes, is to act as auxiliary organs in the production of hemoglobin. They unite synthetically the lower compounds of albumin and iron, which are then stored up in the granules. This product later passes in some way into the blood-plasma, and thence is utilized by the erythrocytes for the formation of hemoglobin, analogously to the hematogen of the yolk in the embryo. From this standpoint the eosinophile cells may be considered as glands of mesoblastic origin, the function of which is to prepare material for the formation of hemoglobin by the erythrocytes. The question why the eosinophile cells appear in carcinoma of the vaginal portion of the uterus, and not in cancer of other organs, and why they accumulate in certain inflammatory processes, can scarcely be answered. We can only assume special conditions of eosinophile emigration—a special eosinophile chemotaxis.

A hitherto Unnoticed formed Constituent of the Blood.—Müller[2] describes minute (1 μ), spheric, colorless granules which he has observed in the blood in health and disease. They are soluble (probably) in ether, insoluble in acetic acid, and are not stained by osmic acid. They have nothing to do with fibrin-formation, and undoubtedly exist preformed in the blood; their nature is unknown. Müller proposes the term **hemokonia** (blood-motes) for these particles.

The Blood-changes in Gastric Disorders.—Blindermann[3] has studied the blood of 18 patients in Wassiljeff's clinic. Eight of these had chronic gastritis, 2 acute gastritis, 4 gastric ulcer, and 4 carcinoma of the digestive tract. In acute gastritis the blood was normal; in chronic gastritis the red corpuscles were normal in number or slightly diminished, the white corpuscles unaffected. In gastric ulcer there was oligocythemia, except in 1 case, in which hematemesis was absent; in the others the diminution was exactly proportional to the amount of hematemesis, chlorosis, and melena. In the cases of malignant disease (3 affecting the stomach and 1 the rectum) there was great oligocythemia, with (except in 1 case) leukocytosis. The percentage

[1] Centralbl. f. Allg. Path. u. Pathol. Anat., Mar. 15, 1896.
[2] Ibid., July 1, 1896.
[3] Wien. med. Blätter, Oct. 31, 1895.

of hemoglobin was much more reduced than in gastric ulcer. The author concludes that—1. Examination of the blood affords a means of distinguishing cancer of the stomach from other gastric affections, particularly chronic catarrh and dilatation. 2. With rare exceptions the differential diagnosis between cancer and ulcer of the stomach is simplified by an examination of the blood. 3. In malignant disease of the stomach there is a progressive diminution of the hemoglobin, while in ulcer there is a sudden great decrease after hematemesis, followed in a few days by a return to normal. The only exception to this is in those rare cases in which pernicious anemia supervenes. 4. Chronic gastritis with dilatation causes no definite changes in the blood.

Billings[1] states that there is in **diphtheria**—(1) oligocythemia; (2) leukocytosis (increase in multinuclear cells). This was missed in only two cases—a very mild one and a very severe one. The oligocythemia is less marked in cases treated with antitoxin.

Blood-changes in Anemia.—Sophie v. Moraczewska[2] from a study of 34 cases of anemia concludes that—1. In pernicious anemia there is a marked diminution of alkalinity, a high specific gravity of the blood, a small count of red corpuscles, and these contain an excess of coloring-matter. The blood is rich in nitrogen. 2. Chlorosis is marked by slight alkalinity, high specific gravity, and a considerable number of corpuscles containing little coloring-matter. 3. Carcinoma is characterized by high alkalinity, low specific gravity, a relatively large number of corpuscles which are pale in color. The blood on drying leaves a small amount of residue.

Hypoleukocytosis in Acute Tuberculosis.—Warthin[3] has studied the blood of 2 cases of acute general miliary tuberculosis, and found that the blood does not give us any aid in the diagnosis between typhoid fever and acute tuberculosis. In both cases there was pronounced hypoleukocytosis.

The Blood after Venesection.—Koeppe[4] found that after venesection in rabbits the first nucleated red corpuscles appeared in the blood in from 20 to 48 hours. The blood-corpuscles increased more rapidly than the hemoglobin, which the author explains as follows: The number of corpuscles is augmented, firstly, by the formation of nucleated corpuscles; and secondly, by the constricting off of microcytes (schistocytes) from ordinary red corpuscles which do not increase the hemoglobin, although they do augment the number of erythrocytes.

Leukocytosis of Diphtheria under Serum-therapy.—Ewing[5] from a careful study of a large series of cases of diphtheria comes to the following conclusions: Diphtheria is usually attended by pronounced leukocytosis. The increase of leukocytes begins a few hours after the infection, probably appearing earlier in refractory individuals. In favorable cases the leukocytosis is greatest at the climax of the disease, and steadily declines during convalescence. There may, however, be prolonged hyperleukocytosis

[1] Med. Rec., Apr. 25, 1896.
[2] Virchow's Archiv, Apr., 1896, Bd. cxliv. p. 127.
[3] Med. News, Jan. 25, 1896.
[4] Münch. med. Woch., Sept. 25, 1895.
[5] N. Y. Med. Jour., Aug. 17, 1895.

after other symptoms have subsided. In unfavorable cases the leukocytosis continues until death, but in somewhat prolonged cases, with much septic absorption, there may be an uninterrupted decrease of leukocytes, continuing up to the fatal termination. A complicating pneumonia usually causes considerable increase in leukocytosis. The degree of leukocytosis in diphtheria often varies with the fever, but much more frequently corresponds to the extent of the local lesion. The intravascular leukocytosis of diphtheria measures exactly the systemic reaction against the toxic products circulating in the blood and absorbed from the site of infection. High leukocytosis in diphtheria indicates a pronounced reaction against a severe infection, but is not necessarily an unfavorable prognostic sign. Steadily decreasing leukocytosis usually, but not always, accompanies a favorable course of the disease. Slight leukocytosis generally indicates a mild infection, but fatal cases may for several days show no increase, or even a decrease, of leukocytes. The staining reaction of the leukocytes is an accurate measure of the severity of a diphtheric infection, and variations in this reaction often precede changes in other symptoms. Antitoxin within 30 minutes after its injection causes a hypoleukocytosis, the reduction affecting especially the uninuclear leukocytes, while the proportion of well-stained multinuclear cells is increased. This action is due largely to the immunizing principle contained in the serum. In favorable cases, after the injection of antitoxin, the leukocytosis never again reaches its original height. In severe and less favorable cases the injection is followed in a few hours by hyperleukocytosis and fever, exceeding those symptoms as found in the original condition. In unfavorable cases an injection of antitoxin may be followed immediately by rapid hyperleukocytosis or extreme hypoleukocytosis and death. The reduction of leukocytes immediately succeeding the injection of antitoxin, especially in severe cases of diphtheria, is an undesirable feature. The multinuclear leukocytes found in the blood of favorable cases after treatment by antitoxin show increased affinity for gentian violet. The failure of this change to occur is a very unfavorable prognostic sign. The variations in the staining reaction of leukocytes in diphtheria indicate that the nuclei of these cells contain a principle essential to phagocytosis and immunity in this disease. In normal rabbits the antitoxin produced also an immediate hypoleukocytosis which varied with the strength of the serum.

Busch and Kerr,[1] working under Williams of Buffalo, determined the **relation of the specific gravity to the hemoglobin-percentage of the blood,** basing their studies on Hammerschlag's table. The method employed for estimating the specific gravity was that devised by Hammerschlag. The necessary apparatus consists of an hydrometer-jar, an hydrometer, a pipet of small caliber, a glass rod, some fine steel pens, a bottle of chloroform, one of benzol, and a mixture of the two. The mixture of chloroform and benzol is poured into the hydrometer-jar. The finger, after being washed with bichlorid and alcohol, is punctured. A good-sized drop of blood is introduced into the chloroform-benzol mixture. If the drop sinks, the mixture

[1] Med. News, Dec. 21, 1895.

must be made heavier by adding chloroform. If it rises, the mixture is too heavy and must be made lighter by adding benzol.

The authors' conclusions are as follows: 1. The percentage of hemoglobin in the blood in most cases may be predicted from the specific gravity with sufficient accuracy to be valuable for clinical purposes. 2. Fleischl's hemometer is liable to an error of 10%. 3. Gowers' instrument is liable to an error even greater than that of Fleischl's. 4. The error in technic with the specific-gravity method is likely to be very slight. 5. In following up a case with Fleischl's or Gowers' instrument very erroneous conclusions may be drawn. Mistakes may be made of 5% or 10% too low one day, and 5% or 10% too high on another. 6. In following up a case the specific-gravity estimation seems to give very slight error, and even if from it the absolute percentage of hemoglobin could not be determined, yet the relative increase or decrease of hemoglobin from one day to another might be quite accurately estimated. 7. Because of its being based on the instrument of Fleischl, Hammerschlag's table is of necessity only approximately accurate.

Pathology of Pernicious Anemia.—Hunter,[1] as is well known, holds that pernicious anemia is of hemolytic origin, and that it is a disease *sui generis*. His reasons for the latter view are—1. The extreme degree of blood-change which it invariably presents is always marked by certain pathologic changes, characteristic either as regards their nature or degree or their peculiar association. These changes are constantly met with in the liver, and not infrequently in the kidneys and spleen. 2. These changes are characteristically absent in traumatic anemia or in wasting anemia. 3. They consist for the most part of deposits of blood-pigment, with corresponding increased richness in iron in the liver, preferably in the liver-cells of the outer two-thirds of the hepatic lobule, frequently also in the capillaries of the liver and within the cells of the convoluted tubules of the kidneys. 4. This pigment is not the result of extravasation. 5. From its character and its amount it denotes an excessive destruction of blood as the prominent and most constant and characteristic feature of the disease. While the hemolysis undoubtedly takes place in the area of the portal circulation (especially in the spleen), it cannot be considered as an exaggeration of the ordinary blood-destruction of health. The existence of extravasations in a frequency sufficient to give rise to pernicious anemia (Stockman's view) has not been demonstrated. Furthermore, as the author has shown by experiments (injecting large amounts of blood into the peritoneal cavity of rabbits), the characteristic pigment-changes in liver, kidney, and spleen in pernicious anemia, and the no less characteristic distribution of the pigment among these organs, cannot be produced by absorption of extravasated blood, however large in quantity. The peculiar distribution of the pigment indicates that there is a special cause, and inasmuch as it occurs in the portal area, the poison probably reaches the blood from the gastrointestinal canal. The nature of this poison is not known; Hunter, however, believes that "it is the presence, under certain favorable conditions, of

[1] Brit. Med. Jour., Feb. 8, 1896.

organisms of specific nature within the gastrointestinal tract." [Hunter's views as to the nature of pernicious anemia are undoubtedly gaining ground, and few will now maintain that it is not dependent on a hemolytic process.]

Studies in the Genesis of Red Corpuscles.—Guitéras[1] records observations on the bone-marrow and spleen in leukemia, which have an important bearing on the subject of cytogenesis. The following points were observed in the bone-marrow: The lymphoid reticulum was thickened and the spaces crowded with a variety of cells. No evidence of the formation of red blood-cells was found. There were numbers of cells that presented the nuclear features said to be characteristic of erythroblasts, but it appeared that they became overgrown with protoplasm or presented evidences of nuclear cell-division without being able to form red blood-globules. The protoplasm of such cells frequently showed unmistakable evidence of the presence of hemoglobin. In the wide channels of the lymphoid marrow cells in all stages of direct nuclear fragmentation and varying forms of chromatolysis were found, as well as cells varying in size from small round erythroblasts to very large cells. With the exception, perhaps, of the true erythroblasts, these cells might be considered as interchangeable, and even the erythroblasts appeared to be subject to such changes as might bring about their conversion into the form of cell described as leukoblast; that is, their nucleus might become gradually poorer in chromatin, and might by degrees assume the loose reticulated appearance characteristic of the larger cells.

One of the cells deserves special attention. Its two nuclei were surrounded by a transparent, homogeneous zone and stained intensely red with safranin. As is shown later, bodies similar to these nuclei are especially concerned in the formation of red blood-cells. Similar cells were found containing even a larger number of nuclei, which might be separated or might be joined together by filamentary prolongations. The protoplasm around them contained hemoglobin. These cells undoubtedly represent ineffectual attempts at the formation of red blood-cells. The successful formation of erythrocytes seems to take place only from free nuclei similar to those found within this mass of protoplasm; furthermore, the successful formation of red blood-cells takes place only in contact with endothelial cells, and in the present case only in the spleen. A marked difference between the cell at present described and the one containing pale nuclei could be noted. The nuclear filaments that might be found joining the fragments of the nucleus in the latter cells were pale and usually thick, whilst the filaments of the multinuclear erythroblasts were stained intensely red and were very fine.

The spleen presented an increase of the connective-tissue reticulum. As in the marrow, a number of parallel channels were found, some lined with endothelium, others not. The point to which the author particularly calls attention is the behavior of the erythroblasts in the immediate neighborhood of the endothelial channels. It is here that for the first time anything like the formation of red blood-globules was seen. The process was about as follows: The small free ery-

[1] Internat. Med. Mag., Dec., 1895.

throblast sent a prolongation of varying length through the endothelial wall from without toward the interior of the vessel. This prolongation just within the endothelial lining swelled into a bud that might be smaller or larger than the erythroblast from which it sprang. This small bud presented the same peculiarities as the erythroblast outside. It was around this bud that the formation of the red blood-cells was seen. These seemed to grow around the bud as a protoplasmic formation around the nucleus, except at the point of contact with the filament. If the bud presented a round shape, the hemoglobin-holding protoplasm was also globular. If the bud was pear-shaped, the protoplasm generally presented the same outline. Occasionally the protoplasm grew more from one side of the nucleus. The union between the erythroblast and the bud might be very close, presenting the appearance of a large diplococcus divided by a line of endothelial membrane. In other cases the filamentary union might be as long as 9 μ. In some cases the bud had evidently been broken off or had not formed, and the end of the filament could be seen pointing in the endothelial wall. When the bud-cells with their hemoglobin envelope are disengaged from the endothelial wall, they constitute nucleated red blood-cells. As some of these nuclear buds were found of very small size, with a large blood-cell around them, it is very probable that the latter may be loosened from its anchorage without any nuclear contents, thus constituting a fully-developed red blood-cell. There was also evidence that the bud may be loosened from its moorings without any hemoglobin-formation about it. In that case it constitutes, the author believes, a true blood-plaque. The erythroblasts engaged in the process of filamentary budding are homogeneous, except that occasionally the bud breaks up into small rays extending a short distance into the red blood-cell. Erythroblasts that are not engaged in the process of filamentary budding are frequently of a larger size. In these a densely packed coil of chromatin may be seen, and sometimes a rearrangement of the mitome in obscure karyokinetic figures. The author is of opinion that in such cells the nuclear matrix may swell before the nucleus divides, and the cell is thus converted into the so-called leukoblast. Though the splenic channels, endothelial or nonendothelial, were frequently crowded with red blood-cells of varying shape, very little evidence of pigmentary degeneration was found. The irregular distribution of these red blood-cells made it difficult to decide upon the nature of the endothelial channels—that is, as to whether they were or were not true capillary continuations of the blood-vessels of the spleen. The author holds they are. For purposes of comparison the spleens of a case of cardiac anemia and of progressive pernicious anemia have been examined. In neither of these have the filamentary figures been found. However, in the case of pernicious anemia the tissues were not fixed in osmic acid, and in the case of cardiac anemia, though the attempt was made to fix the tissues by means of osmic acid, the result was not quite successful, evidently on account of post-mortem changes. In the spleen of cardiac anemia the number of red blood-cells in the spleen-channels was very great. The endothelial cells showed no evidences of division. They were, however, more numerous and more globular

than in the case of leukemia, and projected farther into the endothelial channel. Sometimes they were very close together, leaving scarcely any space between them. The closer together they lay the more prominent and globular they appeared. In the case of pernicious anemia the endothelial nuclei were still more swollen and numerous than in the case of cardiac anemia. The capillary spaces are evidently dilated. In both the spleen and marrow distinct evidences of pigmentary degeneration of the red blood-cells were found.

As to the origin of the erythroblasts, the author holds that all the cells described may develop one from the other through a species of metaplasia, the starting-point of which is probably the lymphocyte. The erythroblast appears to originate in the shape of spheric fragments of chromatin that are thrown off from the nuclei of other cells, and the latter may again develop from the erythroblasts by a process of chromatolysis and swelling of the nuclear matrix. The author, however, admits that the opposite view which gives the erythroblasts a specific character and traces their origin to embryonal red blood-cells is also well supported. He has observed the process of filamentary budding of erythroblasts in the spleen of the rat and the rabbit after hemorrhage. He also noted peculiar bodies resembling sporoblasts in the marrow of the case of leukemia examined. The group consisted of 9 cyst-like bodies, vesicular in structure and having a rod-shaped body near the periphery of the vesicle. Concerning the nature of these bodies, whether they are vesicular degenerations of the nucleus, or red cells the walls of which have undergone some change, or whether they are something else, the author is unable to give a final opinion.

Delbet[1] has discovered a bacillus which he considers the cause of lymphadenoma. He gave a dog 14 injections. The first 3 produced small, rapidly healing abscesses. The animal wasted despite a large appetite, and developed cachexia. Delbet thought that the spleen and the visceral ganglia were enlarged, but could not determine positively. The interesting point was the existence of leukemia, the relation of white to red being as 1 to 60 or 70.

The Influence of Acute Infectious Diseases on Leukemia.—Thorsch[2] discusses this question on the basis of a personal observation. Since Eisenlohr first called attention to the recession of the lymphatic glands and spleen and retrograde changes in the blood of leukemia during the course of typhoid fever, a number of instances have been recorded by others (Heuck, Mincke, Stintzing, Müller, Kovács, and Fränkel). Only 1 case (Müller's) is on record in which an increase occurred, but even in this the increase took place in the multinuclear forms. The author's case was a carpenter aged 42, who had enlargement of liver and spleen, submaxillary, supraclavicular, axillary, and inguinal lymphatic glands. The blood showed on entrance hemoglobin 70%, red corpuscles 5,500,000, white corpuscles 80,000. The patient gradually grew worse; the hemoglobin fell to 30%, the red corpuscles to 4,500,000, the white increasing to 140,000. About 98% were uninuclear leukocytes (chiefly lymphocytes), 2% multinuclear; eosinophiles and nucleated red corpuscles were not found. On Oct. 9th the patient was seized with a chill,

[1] Bull. et Mém. Soc. Chir., 1895, xxi. [2] Wien. klin. Woch., May 14, 1896.

and afterward developed a migrating lobar pneumonia. During the height of the disease the lymphatic glands, liver, and spleen became greatly reduced in size, and the number of leukocytes sank by Oct. 13th to 43,000 (uninuclear 88.7, multinuclear 11.3). As the pneumonic infiltration extended the leucocytosis increased, and on the day of death reached 172,000. Various theories have been advanced to explain the influence which infections exercise on leukemia, but all are unsatisfactory. The author has no explanation to offer, but calls attention to the analogy between the observations in leukemia and the influence of erysipelas on malignant neoplasms, which seem to give support to the view of Barde and Gilbert, that leukemia is related to the true malignant tumors.

Henry[1] reports a case of **parasitic chyluria** with filaria nocturna in the blood. The patient was a woman, aged 29 years, a native of South Carolina. She had been in Philadelphia about a year. The chyluria came on after a normal labor.

DISEASES OF THE CIRCULATORY SYSTEM.

Tuberculosis of the Heart.—Leyden[2] states that there are three forms of cardiac tuberculosis—those affecting (*a*) the heart-muscle, (*b*) the endocardium, and (*c*) clots present in the auricle or ventricle. (*a*) Tuberculosis of the heart-muscle is rare. The presence of the bacillus in such foci has been demonstrated. Apart from the actual occurrence of the tuberculosis, the heart-muscle may undergo fatty degeneration in tuberculosis; fragmentation, as well as brown atrophy, has also been observed, but fibrosis is rare, and when present may have another cause. (*b*) The valves are not infrequently diseased, but as a rule the lesion antedates the tuberculosis. Occasionally the endocarditis is recent. In one such case the streptococcus alone was found. In 4 others examined bacteriologically by Michaelis tubercle-bacilli were found in the valves or endocardium. (*c*) In one of the author's cases Michaelis found tubercle-bacilli in an antemortem clot in the heart. Leyden draws attention to the presence of living bacilli within the cells, and the possibility of new foci arising from a transportation of such cells to other parts. The presence of bacilli in clots the author attributes to the wandering in of leukocytes containing bacilli. This, we believe, may sometimes happen in the exudate of croupous pneumonia, and thus a genuine pneumonia may pass into a caseating tuberculous pneumonia. Labbé[3] reports 2 cases of **tuberculous myocarditis**—one in a boy of 6, the other in a girl of 4 years.

Banti[4] has studied the anatomic **causes of loss of compensation in valvular heart-disease.** For purposes of study the cardiac lesions divide themselves into the aortic and mitral. In the former disturbances of compensation depend on sclerosis of the coronary arteries and their branches. The changes in the intramyocardial vessels lead to narrowing or obliteration of the

[1] Med. News, May 2, 1896.
[2] Deutsch. med. Woch., Jan. 9, 1896.

[4] Centralbl. f. Allg. Path. u. Pathol. Anat., Aug. 31, 1895.

smaller arteries, and this in turn to a simple or degenerative atrophy of the muscular structure, together with hyperplasia of the connective tissue. Small necrotic foci may form which are followed by true scars. The changes in the myocardium are then those of cirrhosis, which, in view of the origin of the fibrous hyperplasia, might be termed *arterial cirrhosis.*

In mitral lesions the mechanism of the disturbance of compensation is different. As a rule, defects of the mitral valve have a shorter course than aortic lesions. Patients with mitral lesions may die in different periods of the disease: 1. In the period of sufficient compensation, in consequence of intercurrent disease. 2. During an early attack of asystole, commonly attributed to fatigue of the heart, death resulting generally from complications, such as embolism, etc. 3. In a more or less advanced period of cardiac cachexia.

The author had opportunities to make autopsies in each of these classes of cases. In the first he found a pure hypertrophy of the myocardium, without microscopic lesion. In the second there was a marked dilatation of the coronary vein and its subepicardial branches; microscopically, the same change was found in the intramyocardial veins and in the capillary network surrounding the muscles. The fibers seemed to be separated by a granular substance soluble in acetic acid and in potassium hydrate. The connective-tissue cells were also the seat of cloudy swelling, and the muscle-fibers of vacuolar degeneration. These changes are evidently due to venous stasis and edema of intermuscular connective tissue and the muscle-fibers. In the cases that died in the period of cardiac cachexia the author found constantly, when the period had lasted sufficiently long, an enormous dilatation of the coronary vein; the walls of the vein and its subepicardial branches were more or less thickened and rigid, resembling walls of arteries. The muscle-cells in the tunica media were fewer than normal or had entirely disappeared. The veins themselves were surrounded by a broad ring of fibrous tissue. The intramyocardial veins were dilated and sclerosed. The muscle-fibrillæ were surrounded by connective-tissue rings, which were thicker and coarser than normal. The origin of this new formation of connective tissue seemed to be the small veins in the intermuscular spaces. The arteries presented no notable change. The muscular fibers were the seat of profound changes, consisting in simple atrophy, vacuolar degeneration, more rarely fatty metamorphosis. In the neighborhood of the veins from which bands of fibrous tissue sprang, the muscle-fibers were often totally destroyed; at some distance simple atrophy was found; vacuolar degeneration existed when the connective-tissue hyperplasia was less advanced. Small areas of hyaline necrosis were also found. The changes described are of a cirrhotic nature, the origin of the fibrous hyperplasia being the veins; it is therefore a *venous cirrhosis,* in contradistinction to the arterial cirrhosis of aortic disease. The development of this cirrhosis is due to disturbances in the circulation in the heart-muscle, which in turn are dependent on imperfect emptying of the coronary vein into the right auricle. The first change affects the muscle-fibers (vacuolar and fatty degeneration), and this facilitates disturbances of compensation. As the myocardial stasis increases, it finally leads to fibrous

hyperplasia, which may remain limited to the veins (phlebosclerosis) or may become a cirrhosis proper. The changes in the myocardium in mitral lesions are thus seen to be analogous to those in the other organs, and to depend on defective contractile power of the myocardium.

Thrombus-like Formations in the Heart.—Bostroem [1] describes 2 very interesting heart-specimens. The first was obtained from a child 3 weeks old, that 3 days before death had become cyanosed, and gradually sinking, had died in collapse. At the autopsy the right auricle was almost completely filled by a globular mass attached to the upper and outer wall of the inner surface of the auricle; its surface was entirely smooth, moist, shining, and grayish-white in color. The cavity of the auricle was reduced to a narrow slit. At first the mass was considered a myxosarcoma, but a careful study of the hardened specimen showed that the mass consisted almost entirely of blood with a surrounding connective-tissue membrane, which was continuous with the wall of the auricle. From this it might be inferred that the mass was a thrombus, but the author gives reasons against this view. At the point of attachment the muscular wall of the auricle was much thinner than normal, its limits very irregular, almost notched, looking as if torn, and the muscle-fibers were separated by a new granulation-tissue. The most striking feature, however, is that this altered muscular wall was in immediate contact with the large blood-spaces of the mass. There was, then, lacking here a part of the muscular wall, the subendocardial tissue, and the entire endocardium. Moreover, in the capsule of the growth, aside from an endothelial covering and subendothelial tissue, muscular fibers were demonstrable; wherefore the author concludes that the mass was the result of a hemorrhage into the muscular wall of the auricle. The cause of this is assumed to be a trauma.

A second communication concerns itself with varices of the auricles and their relation to stalked polypoid thrombi and ball-thrombi. In one of the cases reported a varix 5 cm. long and of the same thickness projected from the posterior lower edge of the open foramen ovale into the right auricle. The varix contained fluid blood and a phlebolith 2 mm. in diameter. Including another case of his own, the author collects 10 cases of varices of the auricles. Nearly all were situated on the posterior quadrant of the foramen ovale. In 9 cases the varix was situated in the right auricle. An additional specimen was found by the author in the collection of the University of Giessen. The mass measured 5.8 by 5.3 by 5.0 cm. (see Plate 7, Fig. 2).

Regarding the significance of these varicose veins, the author believes that they may give rise to polypoid thrombi—one case cited by him seems to confirm this—and also perhaps to a special variety of ball-thrombi. An important point in the diagnosis between a thrombus and a varix is that in the latter the enclosing membrane is separate, independent, and readily peeled off, while in the case of the former it is part of the organized thrombus. We reproduce the plate showing the auricular hemorrhage and the polypoid mass, which, for the reasons given, the author views as a very large varix.

Endocarditis as a Sequel of Gonorrhea.—Dauber and Borst[1] after a review of the relevant literature describe the case of a man who a few weeks after the acquisition of gonorrhea developed a malignant endocarditis of the aortic valve. This was found at autopsy, together with a nephritis. The microscopic examination of the valves, of the heart-blood, of a small abscess in the aortic valve, and of the splenic pulp revealed the abundant presence of a diplococcus which morphologically had all the characteristics of the gonococcus. All nutrient media save one—a serum-agar tube—remained sterile. On the latter minute punctiform, yellowish-brown, translucent colonies developed, which, the authors believe, did *not* consist of gonococci. [In a report on this paper Kolle[2] remarks that the diplococci found may have been gonococci, in favor of which, apart from the morphologic identity, is the fact that despite

FIG. 120.—Syphilitic aortitis (Deutsch. Arch. f. klin. Med., Mar. 13, 1895).

the abundance of organisms in the tissues so few developed on the cultures. This appears to us a pertinent point, but further studies of the endocarditis

[2] Centralbl. f. Bakt., Parasit. u. Infektionskrank., Feb. 21, 1896.

following gonorrhea are necessary, particularly culture-experiments by the recent methods.]

Syphilitic Aortitis.—Döhle[1] believes that there is a characteristic form of aortitis due to syphilis. This is characterized macroscopically by stellate cicatricial retractions and pit-like depressions of the inner surface of the aorta (see Fig. 120). A hyperplasia of the intima (chronic endarteritis) may exist in addition. The retractions are produced by diffuse and gummatous inflammations of the media and adventitia, which lead to the formation of cicatricial fibrous tissue. In places the media disappears entirely, and the intima and adventitia are joined by fibrous tissue. The presence of endarteritis alone is not significant of syphilis. In order justly to describe a disease-process as syphilitic, it is necessary to find the cicatricial changes produced by the inflammation of the media and adventitia. Giant-cells are frequently present. Though not characteristic, they are, apart from tuberculosis and syphilis, rarely found in chronic inflammations from other causes. The inflammatory changes in the media favor the formation of aneurysms.

Syphilitic Disease of the Cerebral Arteries.—Wendeler[2] brings

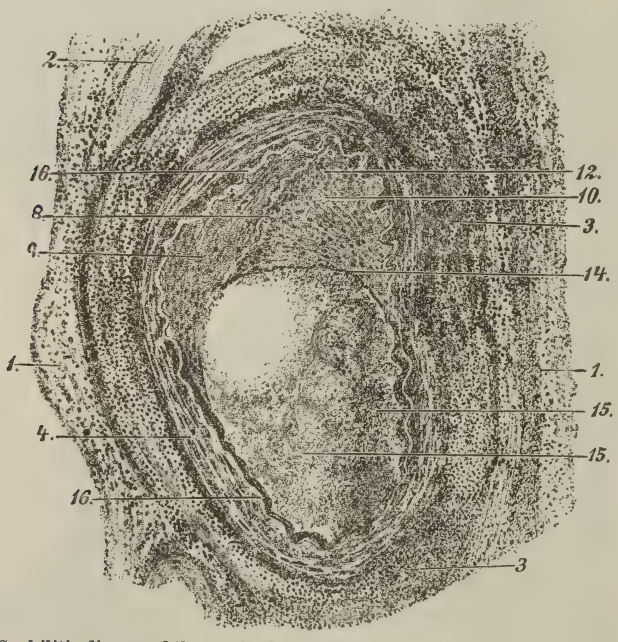

FIG. 121.—Syphilitic disease of the cerebral arteries (Deutsch. Arch. f. klin. Med., Mar. 13, 1895).

forth one important point—namely, that in syphilitic endarteritis there is found, as evidence of the "*schubweise*" proliferation, a new formation of fenestrated membranes. As he has never observed these in endarteritic processes of nonluetic origin, he concludes that the formation of new, well-characterized fenestrated membranes, which are separated by newly-formed

[1] Deutsch. Arch. f. klin. Med., Mar. 13, 1895. [2] Ibid.

tissue from the original one, and which are to be considered as an expression of the interrupted development of the syphilitic endarteritis obliterans, is

Explanation of Reference Numbers on Figs. 121–123.—1, Pia mater infiltrated with leukocytes; 2, fibrinous exudate between pia and adventitia of artery; 3, marked infiltration of adventitia; 4, normal media; 7, vascular formation in the endarteritic hyperplasia; 8, newly-formed fenestrated membrane placed between two foci of endarteritic hyperplasia; 9, 10, hyperplasia of intima formed at two periods; 12, leukocytic infiltration into the endarteritic hyperplasia; 14, newly-formed endothelial membrane; 15, fibrin-mass in vascular lumen; 16, normal fenestrated membrane; 17, endarteritic hyperplasia.

Syphilis and Atheroma.—Weber[1] in a paper on syphilis and the etiology of atheroma enunciates the following conclusions: 1. Atheroma of the aorta, though often preceded or accompanied by inflammation, is itself a merely

[1] Am. Jour. Med. Sci., May, 1896.

degenerative process; syphilitic or other inflammation may locally predispose to atheroma. 2. Aneurysm of the aorta is induced more often by the yielding of a portion of its wall affected by syphilitic or other inflammation than of a portion affected by simple atheroma.

THE NERVOUS SYSTEM.

Spinal-cord Changes in Carcinoma of the Stomach.—Lubarsch[1] found degenerative changes in the posterior columns and posterior roots of 6 cases of carcinoma of the stomach. He believes they are due to the absorption of decomposed stomach-contents.

Progressive Muscular Atrophy.—Cramer[2] publishes an excellent report on the pathologic anatomy of progressive muscular atrophy, from which we abstract the following conclusions: 1. There are muscular atrophies in which, with our present methods, changes cannot be found either in the central or the peripheral nervous system, even in cases of long duration. These atrophies clinically belong as a rule to the type which Erb has grouped together as dystrophy. 2. The muscular atrophies in which a spinal affection is demonstrable present a very variable clinical picture. With the same spinal lesion we may find the symptom-complex of a dystrophy, as also of a spinal muscular atrophy. Even an isolated lesion of the cells of the anterior horns may produce such different disease-pictures. We may, therefore, find in dystrophy a spinal lesion or an intact central and peripheral nervous system. 3. There are transitional cases between those without central and peripheral nervous lesion and those with spinal changes, as also between those of the so-called spinal muscular atrophy and the atrophies found in other diseases of the spinal cord. 4. The muscular changes in the atrophies with spinal lesion and in the myopathies without such lesion are in the main the same, and present nothing characteristic for the different forms. 5. The pathogenesis of the muscle-atrophy is still obscure, but it is probable that an embryonal tendency (*Anlage*), which is hereditarily transmissible, is the causative factor. Whether this supposed embryonal defect affects the nervous system or the musculature directly is undecided. 6. Cases of muscle-atrophy exist with isolated disease of the peripheral nerves, and they are characterized by a special type (neural form of Hoffmann). The muscular changes do not differ materially from those in the other two muscular atrophies. 7. A certain resemblance to those cases is presented by the muscular atrophy of tabes. 8. There are cases of muscle-atrophy of cerebral origin—chiefly cases of focal lesions in the region of the central convolutions. They may develop without any lesion of the pyramids or the cells of the anterior horns of the spinal cord.

Chronic Anterior Poliomyelitis in Diabetes.—Nonne[3] reports a case of atrophic palsy of the upper extremity in a diabetic woman aged 64.

[1] Berl. klin. Woch., Sept. 30, 1895.
[2] Centralbl. f. Allg. Path. u. Pathol. Anat., Aug. 31, 1895.
[3] Berl. klin. Woch., 1896, No. 10.

The palsy began in the arm 1½ years previously and spread to the lower extremities. The diabetes had lasted 4 years.

Multiple Sclerosis.—Redlich[1] discusses the pathology of multiple sclerosis, of which he has examined microscopically about 20 cases. There are three chronic forms: 1. The first form is characterized by dense sclerotic patches, seen especially in the posterior columns. These in transverse section of the cord are formed of granules or points, very delicate parallel fibrillæ, and neuroglia-cells, the processes of which are more numerous and more distinct than in normal cords. Many of the fibrillæ can be traced to these cells, but appear often merely to pass through them, as Weigert has described for the normal neuroglia. The granular appearance is due to transverse section of the fibrillæ. Scattered nerve-fibers more or less altered are found in the sclerotic areas; most of them show changes in the medullary sheath, which may even be absent. The axis-cylinder may be normal, but usually is altered, being swollen or reduced in size. 2. A second type consists of coarse neurogliar trabeculæ not forming distinct foci. They are formed by a thickening of the neuroglia—partly by division of the neuroglia-cells, but chiefly by increase of the neuroglia-fibers. It is impossible to decide whether all the fibrillæ are in connection with neuroglia-cells. The walls of the vessels are often much thickened, poor in cells, and have undergone hyaline degeneration. The neuroglia about the vessels is increased in amount. The sclerosed vessels are not regularly located within the foci, and the vascular change cannot be considered primary. 3. A third form consists of a loose network of slightly thickened trabeculæ, with neuroglia-cells at the points of intersection. Such foci stained with carmin appear light, and are usually near the dense sclerotic patches and close to the periphery of the cord. They are probably due to a relatively rapid destruction of nerve-fibers.

The patches in multiple sclerosis are often symmetric, and are frequently located on both sides of the anterior fissure, but do not correspond to the distribution of any vessel, and are less marked in the lower parts of the cord. The motor ganglion-cells are very resistant to the sclerotic process. In the subacute forms the changes are somewhat different. Fatty cells and acute degeneration of the myelin are noted; sometimes the trabeculæ are a little thickened. The vessels are distended, and their walls infiltrated with cells. Sclerotic foci are common in the pons, but rare in the mid- and interbrain, and are not uncommon in the medullary substance of the hemispheres. They have never been observed in the peripheral nerves. There is nothing histologically characteristic about them except their arrangement. The process is not truly inflammatory, as there are no extravasations or swelling of the tissues; it is more likely degenerative, and probably begins in the nervous elements.

Lapinsky[2] reports 2 cases which clinically presented themselves as spastic paraplegia, but which anatomically proved to be disseminated sclerosis.

[1] Arbeit. a. d. Institut f. Anat. u. Physiol. des Centralnervensystems, edited by Prof. H. Obersteiner, No. 4, 1896.

[2] Zeit. f. klin. Med., 1895, xxviii. p. 362.

The Origin of Tabic Amyotrophy.—Schaeffer[1] has examined the cord from an advanced case of tabes with arthropathy of the knee-joint by the method of Nissl to determine the origin of tabic amyotrophy. While some (Déjérine) consider the tabic amyotrophies due to lesions of the peripheral nerves, others (Charcot and Pierret, Leyden, Condoléon) consider them of central origin. Schaeffer found the cells of the anterior horns of the cervical cord practically normal, but those in the lumbar cord were greatly altered, due to changes in the distribution and arrangement of the chromatic substance. The anterior roots were intact. It is true that in nearly every case of tabic atrophy there is a peripheral neuritis, but this does not exclude a central affection, and does not mean that the peripheral affection is independent of that in the motor cells. The tabic atrophy may have its origin in the primary affections of the cells of the anterior horns. The altered trophic function of the cell is shown first at the most peripheral part of the nerve-fiber, and the intervening portion of the nerve may be intact. In tabes the changes in the ganglion-cells are of very slow development. Destruction of the reflex collaterals from the posterior roots removes much of the stimulus to the cells of the anterior horns, and this leads to structural changes.

Lepra-bacilli in the Spinal Cord of a Fatal Case of Syringomyelia.—Pestana and Bettencourt[2] report an interesting case which, while giving some support to the assertion of Zambaco Pacha as to the true nature of syringomyelia, in the end only proves, as the authors themselves state, that some cases of syringomyelia may be due to leprosy of the nervous system. Their case, a man of 46, presented the symptoms of syringomyelia. At the autopsy the disease was found chiefly in the cervical region. Gliomatous nodules were also found in the bulb. In the lower part of the latter the cavity began; at the same point began a sclerotic process, which grew more prominent lower down. The thickened pia sent in large fibrous trabeculæ into the bulb; there was new formation of blood-vessels and periarteritis. In the cord the changes were more marked, and on staining numerous groups of lepra-bacilli were found. An animal was inoculated with an emulsion of the contents of the syringomyelic cavity, but no disease-phenomena followed, and at the autopsy nothing abnormal was found. The authors conclude that the bacilli were lepra-bacilli and not tubercle-bacilli.

Landry's Paralysis.—Bailey and Ewing[3] found the following lesions in a case of Landry's paralysis in which the nervous system was stained by Nissl's method: Filling of the vessels of the cauda equina; axis-cylinder normal; in some of the nerve-roots perivascular infiltration of round cells; in the spinal cord extensive involvement of the gray matter; intense congestion of all the blood-vessels, especially the anterior branches of the spinal artery; nearly all the vessels showed perivascular infiltration of round cells. There was a diffuse cellular infiltration of the gray matter, at times extending slightly into the

[1] Rev. Neurol., No. 4, 1896.
[2] Centralbl. f. Bakt., Parasit. u. Infektionskrank., May 23, 1896.
[3] Jour. Nerv. and Ment. Dis., May, 1896.

white matter; the central canal was not specially affected. There was more or less complete absence of chromophilic masses in the cells. In the areas where the exudative inflammation was most pronounced, many shrunken cell-bodies without visible cell-nuclei were recognized with difficulty. The lesions were most pronounced in the cervical region. In the medulla the lesions were similar, being most marked in the nuclei of the 6th and 7th nerves. The basal ganglia showed perivascular lesions and foci of cellular infiltration. Throughout the cerebral cortex lesions similar to those in the cord were found. The authors hold that acute ascending paralysis is probably a toxemia, affecting chiefly the spinal cord or medulla, although the cortex and the peripheral nerves might become involved. Diller and Meyer [1] report a case of Landry's paralysis in which the spinal cord presented no macroscopic changes. On microscopic examination the crossed pyramidal tracts were distinctly outlined and more faintly stained than the anterior horns, due to a decrease of medullated fibers and the presence of an increased amount of neurogliar tissue with distended blood-vessels. Defects were also noticed in the posterior columns, but were probably due to postmortem change. Remlinger [2] reports a case of Landry's palsy in a young man, fatal in 11 days. There was no macroscopic lesion in the cord; bacteriologic examination gave pure cultures of the streptococcus.

Polyneuritis with Lesions of Reaction at a Distance in the Spinal Cord.—Marinesco [3] describes a case of polyneuritis in which degeneration was found in the peripheral nerves of the lower extremity; the sciatic nerve was much less involved; the anterior spinal roots were *perfectly* healthy; changes were found in the cord, but only in the lumbar swelling. Here the posterior external group of cells was found diseased when examined by the method of Nissl. As the anterior roots were intact, these changes were due to reaction at distance (*reaction à distance*), were secondary, and were not necessarily permanent. Primary lesions of the cord involve the trophoplasm (unstained portion) as well as the kinetoplasm (chromatophilic elements), and such lesions are irreparable.

The Vascular Changes in Tuberculous Meningitis.—Hektoen [4] in an elaborate article discusses the vascular changes of tuberculous meningitis, especially the tuberculous endarteritis. Nine cases were studied, serial sections being made of the arteries, particularly those in the Sylvian fissure. Extensive vascular changes were present in all of the 9 cases of tuberculous meningitis. From the changes found, together with the usual presence of multiple tuberculous processes in various organs, the inference is justified that the meningitis was of hematogenous origin. The arterial lesions found indicated that an invasion of the wall frequently occurred from within. While the wall in these cases also presents diffuse changes—changes that especially

[1] Am. Jour. Med. Sci., April, 1896.
[2] Compt. rend. de la Soc. de Biol., April 3, 1896.
[3] Ibid., May 16, 1896.
[4] Jour. of Exper. Med., Jan., 1896, vol. i. No. 1.

involve the adventitia, from which they may spread inward—there are also very extensive and important changes in which the intima plays the essential part. Tubercles in the intima may occur in association with more or less diffuse changes in the other coats, accompanied with an extensive endarteritis, or they may occur without any other changes of the arterial segment in the intima of which they are situated. Associated with these typical tuberculous changes is an endarteritis that may occur independently or be connected with infiltration in the media and the adventitia. The presence of this endarteritis without changes in the other layers of the wall, but being confined to the internal surface of an artery throughout its entire extent, shows conclusively that this form of intravascular lesion in tuberculous meningitis may be primary and due to inflammatory agents circulating in the blood. Bearing the fact in mind that such extensive and undoubtedly primary intimal lesions may be present in tuberculous meningitis, it will become exceedingly difficult, if not entirely impossible, to decide where the process may have had its point of origin in the case of more or less diffuse involvement of the arterial wall when associated with endarteritis. Invasion of the media and of the intima from without certainly occurs in tuberculous meningitis as well as elsewhere; as, for instance, in the lungs, and with great frequency. This is shown best by the presence of diffuse or circumscribed adventitial proliferation that gradually extends into the media and reaches the intima perhaps only at one point. In this way an endarteritis due to direct extension from without may arise and extend along in the intima. It seems, however, that an endarteritis distinctly traceable from without rarely reaches the extent of the primary endarteritis. Intimal tubercles with giant cells were not found upon the arteries, in which it could be shown with certainty that the process invaded the arterial wall from without. The tuberculous endarteritis that has been described as occurring primarily and independently of changes in the outer arterial coats demonstrates that tubercle-bacilli are implanted in the intima. The intact endothelium usually present shows that the bacilli must reach the subendothelial layer at once after passing through the endothelial lining. After detailing an experiment in which meningeal and cerebral miliary tuberculosis was produced in a rabbit by injecting bacilli into the carotid artery, and in which the tubercles were found to have developed in connection with the smaller arteries, the author sums up his results in the following conclusions: 1. In tuberculous meningitis there is a tuberculous endarteritis characterized by the formation of intimal tubercles and a diffuse subendothelial, intimal proliferation due to implantation of tubercle-bacilli from the blood. From the endarteritis the infiltration may spread into the muscular coat and the adventitia, and the whole wall may undergo caseous and hyaline degeneration. 2. Tuberculous proliferation in the adventitia may invade the media and the intima, and the whole wall of the arterial segment may undergo degeneration. 3. The veins are constantly the seat of more or less extensive infiltration, which always results from adjacent extravascular or arterial foci. 4. The epithelioid cells of the subendothelial, tuberculous, intimal proliferation

are most likely derived from the subendothelial layer of connective tissue, and not from the endothelial lining.

Cornil and Durante[1] found a pure growth of Pfeiffer's influenza-bacillus in the pus of the pia mater of a woman dead of meningitis, and consider this organism as the cause of the disease.

Hektoen[2] reports a case of **gumma of the hypophysis** in a woman aged 45 years.

Francis,[3] in conjunction with Starr and Van Gieson, reports a case of **neuroglioma of the corpus callosum** in a woman aged 45 years. The tumor measured $5 \times 5 \times 5\frac{1}{2}$ cm., and merged into the tissues of the hemispheres. Localizing signs were absent.

Taylor[4] reports a very interesting case of **secondary sarcoma of the brain** following a primary chondroadenosarcoma of the testicle. The brain-tumors were sarcomatous; in the lung some of the nodules were sarcomatous, others consisted of hyaline cartilage and of glands lined with cylindric epithelium and often dilated into small cysts. Councilman suggested that the secondary growths in the brain were metastatic from the nodules already developed in the lung.

The Action of Alcohol on the Cortical Nerve-cell.—Berkley[5] has studied the changes produced in the brains of rabbits fed for a long period on alcohol. The vascular changes were slight. Very marked departures from the normal were observed in the nerve-elements. In the specimens stained by Nissl's method the nuclei were much altered; the nucleolus appeared rough, spongy, or had elongated projections from the surface; the nucleus was roughened and enlarged. The specimens hardened in Müller's fluid and stained by the author's method (phosphomolybdate of silver in free nitrate of silver) presented the following changes: Tumefactions in the protoplasmic processes of the pyramidal cells of the cortex, and a loss of gemmulæ of the dendrites. The axis-cylinder and its collaterals were normal. The same changes were found in the Purkinje-cells of the cerebellum. The neuroglia in both cerebrum and cerebellum was normal. The author attributes the lesions to a direct action of the poison on the protoplasm of the nerve-cells.

[These investigations—and they have been confirmed with respect to other poisons—raise the interesting question why the prolonged use of alcohol produces interstitial changes in the liver and kidney, in man at least, and parenchymatous changes in the nervous system. As far as we know, no explanation has as yet been offered for this difference in response to the same morbific agent. Poisons acting acutely, as those of the infectious diseases, seem in the main to affect the parenchymatous structures of all organs, the liver and kidney as well as the nervous system.]

The Spinal Lesions caused by Tetanus-toxin.—Marinesco[6] exam-

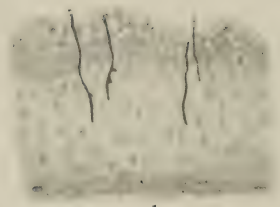
ined the spinal cords of 3 guinea-pigs that had been inoculated with tetanus-toxin. He found small diffuse hemorrhages in the gray substance, most numerous in the anterior horns; the chromophilic elements of the nerve-cells were smaller and altered in shape, in some places changed into granules scattered through the cell-body. In some preparations these elements had disappeared at the periphery of the cells, as has also been seen in hydrophobia and in anemia of the cord from compression of the abdominal aorta; in other preparations they had disappeared also at other parts. The protoplasmic processes presented lesions similar to those of the cell-body. The achromatic substance was deeper in color. In some preparations, where the configuration of the cell was preserved, the entire cell was deeply stained and the altered chromophilic elements could scarcely be seen. The changes were found in the cells of the posterior as well as those of the anterior horns. In the earlier stages the nuclei were not much affected, but in the later their contour was less distinct, the coloration more intense, and the nuclear network had disappeared. The neuroglia-cells were larger. In the later stages of the disease degenerative changes were found in the white substance, and were probably due to alteration in the column-cells.

THE DIGESTIVE TRACT.



Malignant Disease of the Peridental Membrane.—Smith[1] describes tumors springing from the peridental membrane. They are alveolar round-cell sarcomata, containing also many spindle-cells, and occur especially in the periosteum of the molar teeth, particularly the upper. The tumors vary in size from that of a split pea to a small nut, and have a smooth, convoluted, rarely ragged surface. They are firm and of a deep-red color, and seem to be most common in women at the period of the menopause. If the tooth is not removed, malignant disease of the jaw may follow.

Charrin[2] describes a **submaxillary abscess** due to the oidium albicans.

Thrush.—Heller[3] examined 25 bodies in which thrush had been found. In 18 cases in which the esophagus was examined, it was but once found free from the thrush-fungus; once the fungus involved only the epithelium, 7 times the connective tissue, 9 times the connective tissue and the blood-vessels; thrombosis of the affected vessels occurred in 6 cases; once spore-formation was found in a vessel; 3 times the fungus entered the mucous glands; 7 times ulceration was present, always with fungi in the connective tissue; once the threads penetrated into the muscularis. In 7 cases in which the larynx was affected the fungus was confined to the epithelium only twice; in 5 cases it had penetrated into the connective tissue. Similar observations were made on the pharynx and trachea. The lungs were examined in 4 cases: in 2 no fungus was found, in 1 a few threads in pneumonic areas, in 1 case large masses in a dilated bronchus. Fungi were also found in a chronic ulcer of the stomach. In a total of 38 organs examined, 5 were free from thrush;

FIG. 1.—Section of tracheal mucous membrane; threads of thrush-fungus wander through the apparently normal cylindric epithelium into the connective tissue. FIG. 2.—Numerous threads of the fungus in the apparently normal epithelium of a lingual papilla; several have penetrated into the connective tissue. FIG. 3.—Fungus growing through two blood-vessels of the esophagus. FIG. 4.—Cross-section of the esophagus of a child: concentric advancement of the fungus into the deeper parts; partial necrosis and exfoliation of the mucosa. FIG. 5.—Small portion of the same preparation more highly magnified. (Deutsch. Arch. f. klin. Med., Mar. 15, 1895.)

in 4 only the epithelium was affected; in 17 (51.6%), the fungus had penetrated into the connective tissue; in 12 (36.3%), into the blood-vessels, of which 6 were thrombosed; in 9 cases ulcers were present. The epithelium shows no special changes; the connective tissue presents a well-marked reactive inflammation. Metastasis was not observed, and is so far recorded in but 2 cases. The thrombosis of the vessels may explain its rare occurrence. Apart from the local changes produced by the fungus itself, which the author says are not rarely responsible for the serious turn of an otherwise mild disease, it may cause lesions through which bacteria may enter, and cites a case of purulent meningitis and sinus-thrombosis in which the only portal of entrance could have been a necrotic patch of thrush on the vocal cords. (See Plate 8.)

Stooss[1] publishes a series of studies on the etiology and pathology of angina, stomatitis aphthosa, and thrush. In 12 cases of aphthous stomatitis he found constantly a large diplococcus, the properties of which he describes. Less constantly the staphylococcus, "coccus conglomeratus," and other bacteria were found. The author believes that aphthæ are due to the large diplococcus, which is not found in the normal mouth nor in the ordinary anginas. In regard to thrush, he believes that cocci, by causing a stomatitis erythematosa, prepare the mouth for the action of the thrush-fungus.

Bacteriology of Nondiphtheric Angina.—Lemoine[2] has made a careful study of nondiphtheric anginas. Heretofore the organisms found at the diseased focus have been considered pathogenic, without regard to the possibility that as constant inhabitants of the mouth they might be present saprophytically. Lemoine escaped this error by taking the material for cultivation from the interior of the tonsil by means of a pipet, after a preliminary cauterization of the point of puncture. In this way, as well as in a number of instances by the old method, he examined 112 cases of scarlatinous angina, 74 of which presented a membrane, 29 nondiphtheric anginas with membrane, 14 ordinary anginas running a grave course, and a few other anginas, 3 of which were cases of hypertrophy of the tonsils. Excluding the last 3, there remained 165 anginas; in all the streptococcus pyogenes was found, and always in pure culture. When cases were examined without puncture of the tonsils, other bacteria were found, as well as the streptococcus. The 3 cases of hypertrophy of the tonsils showed a bacillus of the colon group. Clinically, there was no difference between the pure streptococcus-anginas and those in which other microorganisms were also present. The virulence of the streptococci toward animals was very variable. Lemoine classes all anginas (those nondiphtheric) as streptococcus-infections, and states that pure streptococcus-anginas (contrary to the usual teaching) may run as grave a course as a grave diphtheria due to the Klebs-Löffler bacillus.

Pepsin in Gastric Diseases.—Oppler[3] finds that pepsin is decreased

[1] Mittheil. aus klin. u. mediz. Institut. der Schweiz, iii. Reihe, H. 1, 1895; ref. in Centralbl. f. Bakt., Parasit. u. Infektionskrank., Feb. 21, 1896.

[2] Ann. de l'Instit. Pasteur, Dec., 1895. [3] Centralbl. f. innere Med., 1896, 5, p. 12.

in chronic gastritis, carcinoma, atony, and dilatation of the stomach; it is increased in ulcer, acid gastritis, chronic gastrorrhea, and sometimes in chlorosis. It seems to go hand in hand with the formation of hydrochloric acid.

Mycoticopeptic Ulcer of the Stomach.—Nauwerck[1] holds that many cases of gastric ulcer begin as hemorrhagic erosions, and that some of these erosions are mycotic in origin, the hemorrhage being in reality a secondary and subordinate phenomenon. Two cases are reported in support of this view. In the one, a youth of 16, who died of heart-disease following rheumatic polyarthritis, the edges of the ulcer showed masses of bacteria—streptococci and diplococci; small areas of necrosis were also present. In the second case, a girl of 7 years, dead of scarlet fever, the stomach showed punctiform hemorrhages, with slight defects of the mucosa, and in the lesser curvature a linear superficial ulcer without hemorrhagic infiltration. Microscopically, the lesions showed the presence of streptococci. This was, then, a septic ulcer. Other infections may produce the same result, as, *e. g.*, the rheumatic poison.

Development of Carcinoma in Gastric Ulcer.—Kelynack[2] records an undoubted case of the occurrence of a cancerous growth in a simple ulcer of the stomach.

Tumors of the Stomach.—Hansemann[3] at the Congress of German Physicians and Naturalists at Lübeck reported the following rare tumors of the stomach: A myoma, with metastasis to the liver and kidney; a myxomatous tumor, with a huge neoplasm of a different nature in the liver; a sarcoma, with hyaline degeneration and calcareous bodies on the outside of the stomach and adherent to the omentum; a submucous tumor, presenting microscopically a resemblance to the cortical substance of the suprarenal capsule. He is not prepared to class the last as related to suprarenal tissue.

False Diverticula of the Intestine.—Hansemann[4] discusses the origin of false diverticula of the intestine. Acquired intestinal diverticula are of two kinds: true diverticula—circumscribed dilatations of the intestines consisting of all the layers; and false diverticula—hernial protrusions of the mucous membrane through the muscular coat. The latter occur especially in the small intestine, on the concave side, and are usually described as being between the layers of the mesentery. Hansemann found in an old man, without history of intestinal trouble, about 400 diverticula, varying in size from that of a hempseed to that of a large pigeon-egg. A few were in the duodenum; in the jejunum and upper ileum they occurred in regular rows. The ascending colon contained none; in the descending colon and sigmoid flexure they were very numerous. Their origin was not in the mesentery, but just alongside of it. In the large intestine true diverticula were present on the convex side, some into the epiploic appendages. On the outside of the intestine small vessels were seen passing from the mesentery by the side of or upon the diverticula, and within the bowel various branches converged into them.

[1] Münch. med. Woch., Sept. 17, 1895. [2] Brit. Med. Jour., Jan. 18, 1896.
[3] Centralbl. f. Allg. Path. u. Pathol. Anat., Oct. 15, 1896.
[4] Virch. Arch., May, 1896, Bd. cxliv. p. 400.

The diverticula were herniæ of the mucous membrane into the sheath of veins, the muscular layer stopping at their edge, even in the case of the smallest. At this location there is a place of least resistance, as can be proved by distending the intestine with water, when similar protrusions occur temporarily.

Obliteration of the Appendix Vermiformis.—Piersol [1] has studied this question, to which attention has recently been given by Ribbert and Zuckerkandl. The appendix attains its fullest development from the tenth to the twentieth year. As the age advances changes take place in the mucosa and submucosa which lead to more or less complete obliteration of the lumen. The first evidence of retrogressive change is a diminution of the size, particularly of the height, of the lymphoid follicles; Lieberkühn's follicles also atrophy. Subsequently the mucosa suffers a general invasion by lymphoid cells. Following the disappearance of the atrophic glands, the opposed surfaces of the mucosa may become united, and the process may be so complete that all traces of the lumen and the mucosa become effaced. These changes must be regarded as phases of a process of involution. Ribbert found them in 99 out of 400 appendices (25%); Zuckerkandl, in 55 out of 232 (23.7%).

Perforation of Intestine by a Polyp.—Zahn [2] reports a case of perforation of the intestine by a rectal polyp.

Cholera Nostras.—Pottien [3] found in the stools of 3 cases of cholera nostras, one fatal, the bacillus fluorescens capsulatus.

Hematogenous Jaundice.—According to Auld [4] the view of Frerichs that jaundice might be caused by the absorption of bile from the intestine has been disproved. Kühne's theory of the origin of a hematogenous jaundice from destruction of the red corpuscles in the blood was overthrown by the experiments of Minkowski and Naunyn. These observers caused ducks and geese to inhale arseniuretted hydrogen, which induced a speedy development of bilirubinuria. On removing the liver from a duck presenting bilirubinuria, hemoglobinuria resulted, with a distinct fall in the bilirubin excreted. At death the urine was free from bilirubin, likewise also 35 c.c. of blood. Subjecting 2 geese, one of which had been deprived of its liver, the other for purposes of control, to the action of arseniuretted hydrogen, the latter had bilirubinuria, the liverless goose only hemoglobinuria.

The jaundice produced by toluylendiamin (Stadelmann, Afanasiew, Hunter) is not hematogenous, but hepatogenous. In many instances, indeed, it is truly obstructive, but in others the poison produces a disturbance in the liver by which a partial deflection of the bile occurs into the lymphatics, and thus into the blood. The author himself experimented with toluylhydrazin and metaphenylendiamin. When slowly introduced they produced a subacute poisoning characterized by jaundice and icteric urine. At the autopsy the spleen was greatly enlarged; the gall-bladder contained but little bile; there was no obvious catarrh of the ducts or duodenum. Microscopic-

[1] Univ. Med. Mag., Sept., 1895. [2] Virch. Arch., Jan., 1896, Bd. cxliii. p. 187.
[3] Zeit. f. Hyg. u. Infektionskrank., 1896, xxi. 1, p. 140.
[4] Brit. Med. Jour., Jan. 18, 1896.

ally, the spleen was found to be enormously charged with pigment of a golden-yellow color. In the liver the portal vein and the capillaries were highly colored by this pigment, carried over, the author holds, from the spleen, which is the organ of blood-destruction. The liver-cells were quite devoid of pigment; they were pale, and in a condition of fatty degeneration. The blood of the hepatic veins contained much pigment, and in the kidney pigment-granules were seen amongst the cells of the convoluted tubules and in the lumina of the straight tubules. It was indisputable that the granular pigment brought to the liver from the spleen was carried over in abundance into the general circulation, and there can be no doubt that pigment existing in soluble form in the blood-plasma was also carried over. Thus, while the liver is ordinarily most active in disposing of the products of blood-destruction, a further stage may be reached in which the liver apparently refuses any longer to deal adequately with those products, its cells undergoing degeneration. The result of this is that the pigments of reduced hemoglobin will be carried beyond the liver into the general circulation, stain the tissues, appear in the urine, and so bring about a true hematogenous jaundice. Two factors are necessary for the production of such a jaundice—an excessive destruction of blood in the spleen, and an inefficient or paralytic condition of the liver-cells. This hematogenous jaundice corresponds to the jaundice brought about by the absorption of the decomposition-products of a large extravasation of blood; the hematoidin of this is, as Virchow has shown, identical with bilirubin. [These are interesting facts, and on their face bear the stamp of probability. They seem to prove the long-disputed occurrence of hematogenous jaundice. They teach us that in yellow fever, pyemia, and other infectious fevers in which jaundice may be present the spleen should be examined as to its pigment-content. If the conclusions are verified by future experiments, we shall be compelled to hold that the liver has but little to do in actively elaborating the bile.]

The Pathology of Jaundice.—Hunter,[1] in researches on the action of toluylendiamin, comes to the same conclusions as Stadelmann, that the jaundice produced by it is in reality due to obstruction. The author believes that an irritative derivative of the poison is excreted in the bile, and induces catarrh of the bile-passages and duodenum. The involvement of the duodenum is secondary to that of the bile-passages, and only occurs in severe cases.

Chronic Perihepatitis (Zuckergussleber of Curschmann).—Rumpf,[2] after briefly describing Curschmann's original case of perihepatitis (Zuckergussleber) details the following instance: A married woman suffered for 15 years from ascites, for which she was tapped 301 times, the quantity of fluid removed varying from 10 to 20 liters. There was enlargement of the spleen; digestion was good; in fact, the functions of the gastrointestinal tract were performed normally throughout her long illness. The autopsy revealed

[1] Jour. of Path. and Bacteriol., Aug., 1895; Brit. Med. Jour., Nov. 16, 1895.

[2] Deutsch. Arch. f. klin. Med., Mar. 13, 1895.

diffuse, chronic hyperplastic perihepatitis, with very marked compression of the otherwise normal liver-tissue; ascites, chronic hyperplastic perisplenitis and parietal peritonitis, diffuse chronic hyperplastic pericarditis, with obliteration of the pericardial sac; right-sided chronic exudative hyperplastic pleuritis; relative insufficiency of the tricuspid valve; edema of the lungs. On section the liver nowhere presented a trace of hyperplasia of the interstitial tissue. The organ was reduced one-half in size, and was covered by a uniform white mass, looking as if congealed. The edges were rounded; the gall-bladder could not be found. The white layer on the liver had a thickness of from 8–14 mm., and was very firm. The kidneys were normal. A microscopic examination was not made. [The condition is very rare; only a few positive cases are recorded. Perihepatitis *with* cirrhosis of the liver is, however, not so infrequent. The diagnosis is difficult; we can only allude to the most important points in the differentiation from hepatic cirrhosis: the absence of signs and symptoms of stasis in the gastrointestinal tract and the long duration are the most important. It is difficult to find a good English equivalent for the German term—we would suggest "icing-liver." In a case studied by one of us recently—a case of cylindric carcinoma of the intestine—the liver was surrounded on its upper surface by a very much thickened capsule, and was partly adherent to the diaphragm. On microscopic examination it was found that the peritoneum was the seat of secondary carcinoma.]

Fussell and Kelly[1] report 2 cases of primary **carcinoma of the liver with cirrhosis.** In Case 1, an Italian aged 44 years, the liver was enlarged, granular, reddish-white, suggesting in appearance a huge carcinoma. Nowhere could a sign of new growth be discovered, the surface of section presenting a uniform lobulated character. Microscopic examination showed cirrhosis of the hypertrophic form; the intralobular biliary canaliculi were increased in number and size. The liver-cells were almost entirely replaced by epithelial cells in the form of tubular cylinders, which seemed to have their origin in the liver-cells themselves (trabecular epithelioma). There was no metastasis to other organs. In the second case, a girl of 16, the liver weighed $3\frac{1}{4}$ lb. and was not hard; the surface was glistening and granular. Small nodules, from the size of millet-seed to that of a pea, were scattered throughout the liver; a somewhat larger mass was found on the surface of the left lobe, and another in the depth of the right lobe. Microscopic examination showed an increase of the connective tissue of Glisson's capsule, and a marked increase in the intralobular biliary canaliculi. The liver-cells were enlarged and cloudy, and on the periphery of certain lobules a probable change from liver-cells into cancer-tissue could be seen. The authors hold the sequence of events in cases of cirrhotic cancer to be as follows: (1) Cirrhosis with hyperplasia of the liver-cells. (2) The embryonal connective tissue gradually becomes fibrous and the liver-cells are converted into cancer-cells. [Siegenbeck van Heukelom[2] holds that this form of carcinoma arises from a hyperplasia of the hepatic epithelium independent of the cirrhosis, although the latter may

[1] Univ. Med. Mag., Aug., 1895.

[2] Ziegler's Beiträge, Bd. xvi. H. 3.

favor the development of the carcinoma. Notthafft[1] looks upon the cirrhosis as secondary and as a defence of the organism against the cancer. While we agree with Notthafft's views as to the origin of carcinoma (see page 706), we must accord to the cirrhosis more than such a subordinate position, and believe that the view of Hanot and Gilbert, that the same irritant acts simultaneously upon the epithelium and the connective tissue, is the correct one.]

Carcinoma of Pancreas.—Miller[2] reports a case of primary carcinoma of the head of the pancreas, without metastasis to any organ. The patient was 53 years old, and had presented all the symptoms of pyloric stenosis, but, HCl being present and lactic acid absent, gastric carcinoma was excluded. At the autopsy an hour-glass contraction of the stomach was found. Sugar was not present in the urine in the few analyses made; the stools were not examined microscopically for fat.

Sarcoma of Pancreas.—Blind[3] presented to the Société anatomique a specimen of sarcoma of the tail of the pancreas, with metastasis to the liver and peritoneum, taken from a man aged 74 years.

Pathogenesis of Abdominal Fat-necrosis.—Ponfick[4] found a bacillus in almost pure culture. The bacillus was obtained from a hemorrhagic focus in the neighborhood of the second lumbar vertebra, and morphologically and culturally resembled the typhoid-bacillus, but gave the indol-reaction; from the colon-bacillus it differed in the mode of growth and in the smoothness, slimy character, and thickness of the colonies. The author believes that the organism probably belongs to the group of colon-bacilli. It is pathogenic for white mice and rabbits; guinea-pigs and dogs resist its action. In the susceptible animals it produces a local inflammation and, if the dose is sufficient, a general infection; necrotic changes were also noted, though only of microscopic character. The author is not prepared as yet to assert that the bacillus is the cause of fat-necrosis.

Gonorrheal Peritonitis.—Bröse, at a meeting of the Berliner medicinische Gesellschaft, Mar. 11, 1896, reported 2 cases of diffuse gonorrheal peritonitis. The disease came on after acute gonorrheal infection. The gonococcus could not be demonstrated.

THE RESPIRATORY TRACT.

The Etiology of Ozena.—Abel,[5] from a bacteriologic study of a large number of cases (100) of ozena, concludes that it is an infectious disease caused by a specific microorganism, termed by him *Bacillus mucosus ozænæ*. It is a rod-shaped organism, 1.25 μ wide and variable in length; it occurs in pairs or chains, has somewhat rounded ends, and is as a rule surrounded by a capsule. The bacteria are readily stained with the anilin dyes, but not by Gram's method. On gelatin-plates they produce, in 48 hours, small, microscopic, brownish-black or grayish-green, finely-striated colonies, which on the surface are ele-

[1] Deutsch. Arch. f. klin. Med., Aug. 29, 1895. [2] Med. Rec., N. Y., Aug. 31, 1895.
[3] Centralbl. f. Allg. Path. u. Pathol. Anat., Aug. 21, 1895.
[4] Berl. klin. Woch., April 27, 1896. [5] Zeit. f. Hyg. u. Infektionskrank., 1896, i. p. 89.

vated. In from 2 to 4 days they are visible with the naked eye. The gelatin is not liquefied. They grow readily on agar at body-temperature, producing, as in the other media, a slimy growth, whence the name; on potato they produce a luxuriant creamy growth; bouillon and peptone-water are rendered turbid. Milk is not altered; in it the bacterium often forms a capsule. The bacillus is nonmotile, contains no spores, and has no flagella. The capsule-formation disappears after one or two generations, except in milk-cultures. Gas-production is slight or entirely absent. The bacillus is pathogenic for white mice, the bacteria being found in all of the organs. Rats and guinea-pigs proved refractory to subcutaneous inoculation; a local process developed after infection into the abdominal cavity or lung. Rabbits are immune. The bacillus mucosus ozænæ closely resembles Friedländer's bacillus, and, while probably distinct, belongs to the same group of pneumobacilli. The bacillus causes small foci of a peculiar secretion which quickly dries to crusts; the accessory cavities of the nose, the middle ear, larynx, and trachea may be affected as well as the nose. In one case the disease was experimentally inoculated into a healthy nose. The fetid odor is not due to the ozena-bacillus, but to other bacteria which find a favorable nidus in the areas attacked by the former.

Oestreich [1] reports 3 new cases of primary **carcinoma of the trachea.**

Bacteriology of Whooping-cough.—Cohn and Neumann [2] found most frequently cocci, among them regular diplococci usually not arranged in chains. Rod-shaped forms were but rarely observed. In cultures streptococci, the nearly constant attendants of respiratory diseases, were almost invariably found; also, but not constantly, diplococci; therefore, it is not possible to look upon these as causative. The bacillus of Afanasiew and the diplococcus of Ritter were seen so seldom that they too cannot be considered the etiologic factors. Kurloff,[3] subjecting the sputum to microscopic examination in the fresh state, found two bodies which he considers parasitic: (*a*) a unicellular ciliated body varying in size from half the diameter of a red corpuscle to a diameter greater than that of the largest white corpuscle; (*b*) a peculiar ameba. The latter is the more important, and is considered by the author the cause of pertussis.

Membranous Bronchitis.—Magniaux [4] reports a case of fibrinous bronchitis in a boy of $11\frac{1}{2}$ years. The formation of the membrane was due to an inflammatory process, the cause being the streptobacillus of Friedländer.

Atypical Croupous Pneumonia, especially Streptococcus-pneumonia.—Harbitz [5] describes 5 cases of atypical, nonpneumococcic pneumonia. The disease began insidiously, with signs of grave general infection, marked cerebral symptoms, and irregular, pyemic fever; all the cases terminated in

[5] Festskrift i anledning af Prof. Hjalmar Heibergs 25 aars jubilaeum, Christiania, p. 249; ref. in Centralbl. f. Bakt. und Parasit., Nov. 15, 1895, p. 593.

death. The lungs presented more or less well-marked lobar infiltrations, generally soft and without granular surface of section; in other cases, bronchopneumonic foci in the one lung, with lobar infiltration of the other. The appearance was very variable, and suggested phlegmonous or erysipelatous processes. In 4 cases only streptococcus pyogenes was found; in 1 case, with notably atypical course, complicated with otitis media, the lungs contained staphylococcus, B. coli communis, and B. pyocyaneus, but no streptococci or pneumococci. The pus from the ear contained staphylococcus and B. pyocyaneus.

The Arthropathies of Croupous Pneumonia.—Vogelius[1] found the diplococcus of Fränkel in the pus of the joint-lesions that had developed in 2 cases of croupous pneumonia. This makes a total of 11 cases in which bacteriologic examination showed the presence of this organism in the arthritic lesions complicating croupous pneumonia.

Primary Actinomycosis of Lung.—Heusser[2] describes a case of primary actinomycosis of the lung in a woman of 50 years, which presented itself with the symptoms of a tuberculosis with cavity-formation, secondary to an exudative pleurisy.

Aspergillosis of Lung.—Renon[3] reports the occurrence of aspergillar tuberculosis in husband and wife, who were engaged in carding hair obtained from rag-pickers.

Etiology and Pathologic Anatomy of Lobular Pneumonia, especially of Aspiration-pneumonia.—Kreibich,[4] after reviewing the literature of the subject, propounds the following questions: (1) What bacteria are found in lobular pneumonias, especially in those due to aspiration? (2) Which of those found are concerned in the production of the inflammation? (3) Is the character of the exudate dependent on the species of bacteria found? He examined 27 lobular pneumonias (20 due to aspiration) and 1 lobar pneumonia. The diplococcus pneumoniæ was found in 23 cases—11 times alone, 5 times with the bacillus coli, 4 times with the staphylococcus aureus, once each with the streptococcus, bacillus pneumoniæ, and an unknown bacillus. The streptococcus was found twice in pure culture. The bacillus coli was found 7 times; in pure culture in the case of lobar pneumonia. In reply to the second question the author states that aspiration-pneumonia is usually caused by the diplococcus of pneumonia, although the bacillus coli is capable of producing lobar pneumonia and of taking part in the production of lobular pneumonia. The colon-pneumonias are the result of hematogenous infection from the intestinal or urogenital tract. In regard to the third question the answer is not definite. The author divides his cases into those terminating in suppuration, in gangrene, and in induration. The termination seems to a large extent to depend on associated bacteria.

Empyema due to Friedländer's Capsule-bacillus.—Wolf[5] reports

[1] Arch. de Méd. expér. et d'Anat. path., Mar., 1896.
[2] Berl. klin. Woch., 1895, No. 47. [3] Jour. des Conn. méd., 1895, No. 44.
[4] Monograph, Wilhelm Braumüller, Vienna, 1896. [5] Berl. klin. Woch., Mar. 23, 1896.

a case of right-sided pneumonia with limited pleurisy, followed, after an atypical course, by interlobar empyema rupturing into the lung. The cause was Friedländer's diplobacillus.

Empyema due to Proteus Vulgaris.—Charrin[1] in an empyema occurring in a puerperal woman found pure cultures of proteus vulgaris.

Etiology of Pleuritis.—Thue[2] has studied bacteriologically 35 serous pleurisies and 23 empyemas. Of the first, 1 was tuberculous, 1 cancerous, a third developed during an attack of acute articular rheumatism; the others presented the symptoms of simple pleuritis without a lung affection. A subsequent examination showed that 60% of all the patients died within a relatively short time of tuberculosis. From the fluid of the pleurisies the author made cultures and inoculated animals, and made cover-glass preparations from the sediment. Examinatiou was negative in 18 out of 30 cases; in the remaining 12 the tubercle-bacillus was found once, the streptococcus once, cocci of unknown species twice, staphylococcus pyogenes aureus and albus once, staphylococcus pyogenes albus alone 3 times. In the 23 empyemas the pneumococcus was found 14 times, streptococcus twice, streptococcus and saprophytic organisms twice, streptococcus and staphylococcus once, staphylococcus albus once, tubercle-bacillus once; no bacteria in 2 cases (pyemic and tuberculous). [These are interesting studies, particularly with regard to empyema, showing the great preponderance of the pneumococcus over the ordinary pyogenic organisms. The pneumococcus was also found in 3 cases of serous pleurisy which, however, soon became purulent.]

Pleurisy in the Course of Gonorrhea.—Bertrand[3] states that the pleurisy following gonorrhea may be dry or effusive, is usually mild, and short in duration. Gonococci have been found in the effusion by Chaiso, Isnardi, and the author, and on cultivation by Mazza.

THE URINARY TRACT.

Albumosuria.—Harris,[4] after stating the characteristic reactions of albumose as given by Munk, describes his method of qualitatively determining the presence of albumose in small quantities. He rejects the term peptonuria, since the substance upon which this name is based is really an albumose. The urine was examined in a great variety of states. The diagnostic value of albumosuria, as far as suppuration is concerned, is stated as follows: Given a patient with a probable circumscribed inflammatory condition, in which the infective diseases can be excluded, the presence of albumose in the urine is quite positive evidence that the condition is inflammatory, and that suppuration has taken place.

The final conclusions are: 1. True peptone being very rarely, if ever, found

[1] Mercredi méd., June 19, 1895.

[4] Am. Jour. Med. Sci., May, 1896.

in the urine, the term peptonuria should be replaced by the term albumosuria. 2. The albumoses are produced by the digestive or peptonizing action of microbes on the albumins of the body. 3. This digestive action is one common to all living organisms. 4. The albumoses are produced in quantities much in excess of what are appropriated by the microbes for their growth and development. 5. The albumoses being readily diffusible, the excess in production is quickly absorbed by the blood, from which, being toxic and acting as foreign bodies, they are eliminated by the kidneys and appear in the urine. 6. Albumosuria may be present in any condition or disease due to the action of microorganisms within the body, and is thus simply indicative of an infective state.

Krehl and Matthes[1] found an **albumose in the urine** of febrile patients which produced fever when injected into guinea-pigs.

Relation of Uric-acid Elimination to Leukocytosis.—Kühnau[2] found that an increase in the number of leukocytes (as in leukemia, croupous pneumonia, sepsis, malignant neoplasms) was always followed by an increased elimination of uric acid. The increase was not dependent on the fever alone.

Rumpf[3] found an increase in the excretion of **ammonia in the urine of cases** suffering from croupous pneumonia, typhoid fever, influenza, rheumatic arthritis, and bronchitis with arthritis. He believes that the increase depends, in general, on the augmented metabolism.

Carcinoma of Ureter.—Hektoen[4] reports a case of primary carcinoma of the ureter in a woman of 50 years.

The Action of Poisons on the Epithelial Cells of the Convoluted Tubules of the Kidney.—Vandervelde[5] has examined the kidney in Asiatic cholera, cholera nostras, acute tuberculosis, and diphtheria, and in various forms of poisoning (chromic acid, lead) experimentally produced in animals, and has reviewed the observations of others on pneumonia, influenza, poisoning by zinc oxid, phosphorus, and mercuric chlorid, and finds that in all of these a toxic substance brought to the kidney by the blood exercises a harmful influence on the cells of the convoluted tubules. The lesions produced are cloudy swelling, fatty degeneration, and coagulation-necrosis. The protoplasm is chiefly affected; the nuclear changes appear much later.

Changes in the Kidneys of Atrophic Infants.—Simmonds[6] in 60 autopsies on infants that had died of pedatrophy, found lesions of the renal epithelium of greater or less degree in all cases, varying from mild cloudy swelling to fatty degeneration, with small exudates into the capsule of Bowman. In many cases the tubules contained casts. Regarding the cause of these renal changes, the author excludes gastrointestinal catarrh, since no case presenting such a condition is included in the series of 60 cases; the influence of drugs, of rickets, of catarrhal pneumonia is also excluded, and no other

complication remains except middle-ear disease. This was noted in 28 out of the 60 cases; however, in only 29 was the condition looked for. In 5 only out of another series of 133 infants on which autopsies were made was otitis media absent. Cultures of the contents of the middle ear, whether these were purulent or not, gave immense numbers of bacteria, among them Fränkel's diplococcus, Friedländer's pneumobacillus, the streptococcus pyogenes, the staphylococcus, the bacillus pyocyaneus, and others. Cultures from the kidneys (5 positive cases) showed the bacillus pyocyaneus 4 times. The author agrees with Kossel that this organism is far more virulent for infants than for adults. In cases where organisms could not be demonstrated in the kidney, the lesions may have been produced by toxins. The author's conclusions are that the renal lesions of atrophic infants in the majority of cases depend on middle-ear disease, and that this, with the consecutive degeneration of the kidneys, is one of the most frequent causes of death of such infants. (See Plate 9.)

The Etiology of Suppurative Nephritis.—Wunscheim[1] publishes an exhaustive study on this subject made in Chiari's laboratory, of which we give the conclusions: 1. Suppurative pyelonephritis in the great majority of instances is caused by the bacillus coli communis, in the minority by proteus vulgaris or the common pyogenic cocci; 2. In those cases in which the ordinary pyogenic organisms are the cause, a consecutive pyemia is usually developed; 3. The pyelonephritis produced by the staphylococcus and streptococcus differs not only by reason of the usually associated pyemia, but also microscopically by a more marked destruction of tissue and the absence of the local hyperplasia, from that excited by the bacillus coli communis; 4. It is not probable that the typical picture of ascending pyelonephritis can be produced by "descension"—*i. e.* by elimination of microorganisms that have entered the blood-stream from the bladder.

On Kidney-tumors derived from Suprarenal "Rests."—McWeeney[2] describes 2 renal tumors which on microscopic examination were found to present the features of suprarenal tissue. The presence of large fat-globules in many of the cells, coupled with the absence of indication of degenerative change—this being a normal condition in the adult suprarenal—strengthened the diagnosis.

The author discusses the nature of these growths—are they sarcomata, carcinomata, adenomata, teratomata? The following characters seem to point to carcinoma: 1. The cells are obviously epithelial; 2. The stroma does not penetrate between them, but divides the cell-groups into elongated or circular alveoli. However, considering the mesoblastic origin of the suprarenal—from the celomic epithelium—the tumors might, according to the views of Waldeyer and Thiersch, be considered sarcomata. For the present the author prefers to call them kidney-tumors derived from suprarenal "rests," instead of carcinomata or sarcomata. Lubarsch[3] collected 30 cases, which are summarized as follows: *Sex.*—Out of 29 cases cited by Lubarsch, 20 were those of males.

[1] Zeit. f. Heilk., xv. p. 287. [2] Brit. Med. Jour., Feb. 8, 1896.
[3] Virch. Arch., Bd. cxxxv. p. 104.

Both of the author's patients were females. *Age.*—Out of 29 cases, 21 were between 40 and 79; 8 between 2½ and 39. One of the author's cases was 53, the other 38. *Side.*—The right kidney was affected 12 times, the left 11. In both of the author's cases the left was the seat of the disease. *Duration.*—This is usually long, 2, 6, and even 10 years elapsing from the time of appearance of the first clinical symptoms. Askanazy's patient felt the tumor when very young; it disappeared for a time, and returned fatally when he was 53. The tumors grow slowly at first, and then seem suddenly to produce cachexia and prove fatal. *State of Urine.*—This seldom yields positive evidence of the existence of the tumor. It did so, however, in Grawitz' first case, though the indications were susceptible of misinterpretation. *Metastases.*—These were found 20 times out of 29, a fact which proves the malignant tendency of these suprarenal neoplasms. One of the author's cases recovered; on the other necropsy was refused. [Regarding the nomenclature of tumors derived from mesoblastic epithelium, it appears to us that Waldeyer's and Thiersch's views cannot be strictly followed. If the tumor presents the histologic features of a carcinoma, it should be called so. After all, the mesoblast is a derivative of the hypoblast, and forms epithelial-like cells—as, *e. g.*, in the kidneys—that bear more resemblance to hypoblastic epithelium than they do to mesoblastic cells, as represented by the connective and lymphoid structures. We cannot see why mesoblastic epithelium, using the term epithelium in the morphologic sense, cannot form adenomata and carcinomata just as any other secreting epithelium. Every one accepts the occurrence of carcinoma of the uterus, and yet this organ is mesoblastic in origin.]

THE DUCTLESS GLANDS.

Graves' Disease.—Farner[1] has examined the goiter in 10 cases of Graves' disease. Of these 8 were diffuse and 2 nodular goiters. The diffuse were divisible into three groups. In the first the alveoli were large and filled with colloid material, and were distinguished from those of normal thyroids only by the presence of colloid in the lymph- and blood-vessels and between the fibers of the stroma. In the second group the follicles were smaller, and usually only partly filled with colloid, which was not so shining as in the first group. The septa contained less colloid in the connective tissue and lymphatics, but just as much in the veins. The epithelium showed a tendency to form papillæ. The thyroids of the third group contained many solid cell-masses, of which some were follicles filled with desquamated epithelium, others lobules and groups of lobules made up of narrow cell-strands. In the nodular goiter some lobules attained a diameter of ½ to 3 cm.; others were compressed to a diameter of $\frac{1}{10}$ mm. Many nodules were made up of solid cell-strands, containing in numerous places balls of colloid matter. Other nodules consisted of small solid cell-masses; still others resembled the ordinary colloid goiter. The first group of diffuse hyperplastic goiters showed hypersecretion; the second, an increase of function associated with an alteration in

[1] Virch. Arch., Mar., 1896, Bd. cxliii.

the secreted matter, allowing more ready absorption; while in the third group the increased activity of the gland manifested itself partly in hypersecretion, partly in the formation of solid cell-masses.

Lubarsch [1] at the Congress of German Physicians and Naturalists at Lübeck described the changes found by him in the thyroid gland in cases of Graves' disease. Glandular follicles were rarely found, but chiefly cystically dilated spaces lined by epithelial cells, with more or less marked papillary formation; the spaces contained little or no colloid, but a fluid of mucoid nature. Regarding the pathogenesis of Graves' disease, Lubarsch is of opinion that the thyroid changes cannot be considered secondary to primary alterations in the sympathetic or medulla oblongata; on the other hand, it is not possible to explain the whole symptom-complex by the thyroid changes. Hypersecretion of colloid cannot be the cause of the disease, since in the enlarged gland in morbus Basedowii almost no colloid is secreted. Probably we are dealing with a common factor which produces both the changes in the nervous system and those in the thyroid gland.

Diplococcus-strumitis.—Heddaeus [2] reports a case of acute strumitis produced by the diplococcus of Fränkel-Weichselbaum, and followed by a secondary metastatic croupous pneumonia. [By strumitis is understood an inflammation of a goitrous thyroid gland. It seems that inflammation of a normal thyroid is rare; we have seen a case in which malarial infection was possibly the causative agent.]

The Importance of the Spleen in Infectious Diseases.—This subject has been investigated by a number of scientists, whose conclusions, however, are not in accord. Metschnikoff and his school hold that the cells of the Malpighian bodies act as phagocytes and destroy bacteria. Nikiforow denies this relation of the spleen to immunity, at least as far as relapsing fever is concerned, upon which Metschnikoff based his studies. Tiktin comes to similar conclusions after experiments on monkeys. Tizzoni and Cattani in their recent studies found no noteworthy difference between splenectomized and nonsplenectomized rabbits, although earlier experiments had led them to form an opposite opinion. Bardach (tetanus, Schweinerothlauf, and ricin) and Kanthack (bacillus pyocyaneus) could not demonstrate any influence of the spleen. Montuori found that the blood of splenectomized rabbits for a time loses its bactericidal properties, but that these subsequently return. Hence he considers the spleen as one source of the bactericidal element of the blood. Kurlow, using rabbits, found that the removal of bacteria from the blood was not a specific function of the spleen, and believes that it is brought about by the physical peculiarities in structure of all organs possessing a fine and abundant capillary network. The subject has now been studied, with careful attention to the flaws of previous experiments, by Melkinow-Raswedenkow,[3] who also used rabbits in his investigations. His conclusion is that splenectomy is a weakening factor in the immunization of animals, but the spleen itself does

[1] Centralbl. f. Allg. Path. u. Pathol. Anat., Oct. 15, 1895.

[2] Münch. med. Woch., May 26, 1896. [3] Zeit. f. Hyg. u. Infectionskrank., 1896, xxi. 3.

not play the role in the battle against the microorganisms assigned to it by the adherents of the phagocytic theory.

Experimental Addison's Disease in the Sewer-rat.—Boinet[1] removed both suprarenal capsules in 109 rats, ligated them in 20, and used various irritants in another series to produce inflammatory changes in them. In half of these animals a black pigment was found in considerable quantity in the blood, similar to that found in the tissues of 2 cases of Addison's disease; in one-fourth of the cases it existed in less quantity; and in the remainder it was not found. The subcutaneous cellular tissues, the mucous and serous membranes, and the lymphatic glands were considerably infiltrated with pigment in certain rats examined some months after the operation; and this infiltration was most pronounced in 3 rats that had been subjected to the exhaustion of constantly-repeated electric shocks. The rats sometimes exhibited symptoms of asthenia and paresis. In one case the gland exhibited the typical cheesy degenerative change of Addison's disease. The extract of the muscles of the Addisonian rats was very poisonous, causing death in a normal rat in 3 days, and a much smaller quantity killing a rat, the adrenals of which had been removed 4 days previously, in a few hours. This toxicity is increased by producing a state of exhaustion in the animals.

TUMORS.

Israel[2] found **two primary cancers in the same individual**—a cylindric carcinoma of the gall-bladder and a "cancroid" of the pancreas. According to Schimmelbusch, there are 3 forms of primary multiple cancer: 1. Multiple carcinoma in the same system, especially in the skin; 2. The supposed primary cancers of symmetric organs; 3. The rare occurrence of primary cancers in different organs, as in this case. [In the absence of illustrations and minute description we cannot state the exact nature of the pancreatic "cancroid."]

Heller[3] describes **bile-forming cancer-nodules in the lung** secondary to carcinoma of the liver.

Intrathoracic Tumors.—Pepper and Stengel,[4] from a careful examination of the literature and their own experience in 9 cases, are led to the conclusion that the majority of intrathoracic tumors are sarcomata, and that the most frequent point of origin is the anterior mediastinum, in particular the remnant of the thymus gland.

Endothelioma.—Hansemann[5] maintains that the term endothelioma comprises, morphologically, more than a single class of tumors. One group comprises tumors having a distinct alveolar architecture, which were formerly described as carcinomata; another group are sarcomata; a third consists of combinations of the previous two; a fourth comprises various tumors, all charac-

[3] Centralbl. f. Allg. Path. u. Pathol. Anat., Oct. 15, 1896.
[4] Internat. Med. Mag., vol. iv., Nov., 1895.
[5] Deutsch. med. Woch., 1896, No. 4.

terized by prominent changes in the stroma; a fifth group represents tumors resembling the adenomata. The clinical course of all of these is variable: the second and third are malignant; the first are like true carcinomas; those of the fourth group are generally benign, but at times present local malignancy, and the adenomatous forms are similar. In conclusion Hansemann proposes the following classification: 1. Carcinoma endotheliale; 2. Sarcoma endotheliale; 3. Carcinoma sarcomatodes endotheliale; 4. Endothelial tumors with specific development of the stroma (cylindroma or siphonoma; myxoma; chondroma; scirrhus; mixed forms approaching sarcoma or carcinoma); 5. Adenoma endotheliale. [In the whole chapter of tumors the group termed endotheliomata stands in the greatest need of clarification. While the foregoing paper does not completely elucidate the question, we think Hansemann has taken a step in the right direction. In many respects endothelium resembles epithelium, and it would be better, it appears to us, for the purposes of the pathologist to consider it more closely related to epithelial than to connective tissue. Adopting this view, we can see how it—*i. e.* endothelium—could produce carcinomatous growths, and even adenomas, although we have not seen anything like that. This would explain then the reported occurrence of primary cancer of the pleura and the peritoneum.]

Dermoid Cysts and Teratomata.—From an elaborate monographic article on this subject by Wilms[1] we abstract the following conclusions: 1. The dermoid cysts of the head, thorax, and a part of the cysts of the retroperitoneal and retrorectal tissues are produced by misplacement of tissue in invagination of glandular structure or coalescence of fetal clefts; 2. A part of the teratomata at the base of the skull and in the abdominal cavity are to be considered as double monsters and as analogues to the fetal enclosures; 3. Excepting those originating in the ovary, all dermoid cysts are either pure dermal cysts or contain in addition such tissues as occur in the neighborhood; 4. The ovarian cysts must be separated, both in view of their structure and origin, from the other dermoid cysts; 5. The dermoid cysts of the ovary originate from a three-layered germinal mass which strives to develop in accordance with the development of the human fetus, and permits us to recognize, even in the arrangement and position of the organs, a similarity to the latter; 6. In consequence of the hindrance to growth produced by mechanic pressure the tissues and parts first differentiated reach a fuller development and choke the others. This accounts for the prevalence of the ectoderm and the cephalic region; 7. Apart from this law of earlier differentiation there is in the development of certain organs another important factor—the difference in the energy of growth of various species of cells; 8. Both in the structure and form of the individual tissues and organs the malformation develops, in case mechanic interference does not disturb, in complete accordance with normal conditions; 9. The circulation of blood in the ovarial parasite is regulated by the maternal organism, but the malformation may in part supply its vascular system, and may participate, under certain conditions, in the formation of the

[1] Deutsch. Arch. f. klin. Med., Mar. 13, 1895.

blood; 10. Since with the circulation the nutrition and the elimination of waste-products are controlled by the mother, we have probably accounted for the constant absence of certain organs, as liver and kidney; 11. The dermoid cysts of the ovary are, therefore, parasitic fetuses, which are best classed in a separate group under the name of *rudimentary ovarial parasites.*

Amyloid Degeneration in Tumors.—Lubarsch [1] describes the occurrence of amyloid degeneration in certain tumors, generally endothelial growths.

Etiology of Tumors; Protozoa and Blastomycetes.—Ribbert [2] brings further evidence in support of his theory of the origin of carcinoma. According to him, the primary lesion of cancer is an active, inflammatory proliferation of the subepithelial connective tissue. The consequent lengthening of the papillæ is followed by an overgrowth of the epithelium covering them. This is, however, unimportant and secondary. Connective tissue now grows into the lengthened glands, and gradually parts of them are separated and isolated. Now begins the characteristic feature of cancer-formation: freed from the restraining power the organism exerts by means of mechanic and biologic influences, and by which the growth of cells is kept in check, the groups of isolated cells grow with an activity that the other tissues cannot withstand, pressing into the spaces of the connective tissue, and including some of its fibers and cells to form the alveoli.

A separation of tissue-elements from their proper relation, either in intrauterine or extrauterine life, Ribbert believes to be the cause of all tumors. In support of this theory he cites the following: 1. The site of an incipient cancer is always raised above the surrounding surface; this is caused by a subepithelial connective tissue rich in cells; 2. While in this way the papillæ may be lengthened to two or three times the normal size, requiring a local hypertrophy of the epithelium to cover them, it can be shown that the deepest points of the glands do not project below their normal position. The epithelial cells appear stretched and the arrangement of the vessels of the papillæ is normal; 3. That at this point the epithelium should suddenly take on an active growth, overcoming the resistance of the connective tissue, and growing in direction opposite to the normal, is unnatural and requires a special explanation. It is more in accordance with biologic principles to assume that the previous connective-tissue growth continues, and, as in other conditions we find phagocytes and lymphocytes in epithelium, so here the connective tissue grows in between the cells.

Notthafft,[3] in a well-written article, attacks Ribbert's theory of **the origin of carcinoma** set forth above, on the basis of a careful study of 3 incipient carcinomata. Nothing was seen indicating an advance of the connective tissue into the epithelium; on the contrary, the impression was that the tumor pushed the closed layers of the connective tissue in front of it and compressed them. In regard to Ribbert's view that many carcinomata originate on the base of tuberculous lesions through which the subepithelial hyperplasia is produced,

[1] Centralbl. f. Allg. Path. und Pathol. Anat., Oct. 15, 1895.

[2] Virch. Arch., cxli. p. 153, July, 1895. [3] Deutsch. Arch. f. klin. Med., Aug. 29, 1895.

the author holds that tuberculosis may favor the later development of carcinoma, perhaps by creating a predisposition, but there is no proof of the separation of epithelial by connective-tissue cells in the sense of Ribbert. The author finally concludes with the statement that carcinoma can arise without previous changes in the subepithelial or submucous tissue, though it may also develop secondarily to a primary connective-tissue hyperplasia.

Kahane[1] in a lengthy theoretic paper discusses the origin of carcinoma from the biologic standpoint, which, he believes, is the only one through which a correct understanding of the subject can be attained. On examining living tumor-particles he found both in carcinoma and sarcoma the blastomyces described by Busse and by Sanfelice, as also motile sporozoa. The blood of persons suffering from malignant growths presents marked degenerative phenomena, and also "paracytic" elements probably identical with the motile sporozoa of the tumor. The cells of the tumor are seen to take up red and white corpuscles in large numbers (*cytophagy*). The chief characteristics of tumor-cells are—(1) *lymphotropy*, and (2) regenerative tension (*regenerativ Spannung*). Lymphotropy is a peculiar attractive energy which the cells possess toward the lymph, which explains softness of tumors according to their malignancy; the consistency does not depend on the blood, which, on account of the imperfect vascularization, is not sufficient to nourish the cells; the latter receive their nutriment from the lymph. The increased metabolism thereby rendered possible produces a greater proliferation of the cells. As regenerative tension Kahane designates the tendency of cells to regenerate rapidly. If a chronic irritation increases this regenerative tendency within the cells, the transition to tumor-growth is given; perhaps a slight trauma or a displacement of the epithelium is sufficient. [It cannot be said that these considerations materially serve to clear the obscure question of the pathogenesis of malignant tumors. Kahane, moreover, does not state what part the parasite plays in the matter.]

The Parasitism of Carcinoma.—Schwarz[2] presents us with a careful critical discussion of this question, based on a thorough knowledge of the literature and a personal study of a large number of carcinomata. After showing that most of the bodies designated as carcinoma-parasites are really products of degeneration, he states that the bodies described by Steinhaus, Siegenbeck, Stroebe, Thoma, Sjöbring, and especially by Ruffer, Walker, and Foa, cannot be included in the same class and must be studied apart. His own researches revealed similar cell-enclosures, which he divides into three groups: the plasmoid, the cytoid, and the cystoid. Using a stain composed of gentian-violet and safranin, the enclosures of the first group appear as minute, pale-blue, oval or round particles. They are situated in a vacuole of the cell. The cytoid enclosures have a nucleus and a nucleolus, and are situated eccentrically in the cells. The cystoid enclosures are the most complicated, and consist of several bodies united together to form one enclosure.

[1] Centralbl. f. Allg. Path. u. Pathol. Anat., vi. 17, 1895.

[2] Beiträge z. klin. Med. u. Chir., 1895, H. 12.

The enclosures described were found only in carcinomas of glandular origin, not in squamous epithelioma. They were also present in the metastatic growths. The author then proceeds to sketch a cycle of development of the parasite, consisting of four stages. But after minutely describing these stages and comparing certain phases to gregarines, the author, by a *reductio ad absurdum*, which comes like an unexpected dénouement in a novel, points out that what he describes are really not stages in the life-history of a protozoan, but that a part of the enclosures are altered leukocytes. This breaks the chain of evidence, and the whole hypothesis falls. Some of the plasmoid enclosures are degenerative products of Altmann's granules; the cytoid and cystoid formations are probably enclosed cancer-cells.

A Protozoan in Lipoma.—Vedeler[1] believes that the origin and growth of lipoma and the development of the enclosing capsule can only be explained on the assumption of the existence of some irritant. This he claims to have found. The piece of tumor was fixed in 5% sublimate solution, the fat extracted with ether, the tissue stained with hematoxylin and eosin, and imbedded in paraffin. Two classes of bodies are described: an opaque one, up to 16 μ in diameter, and a brighter one, with clearly defined capsule, a vesicular nucleus, and granular protoplasm. They are supposed to be stages in the life of the protozoan of lipoma. The bodies are found nearest the capsule. [It is needless to say that we cannot follow the author in conclusions based on such a limited investigation.]

The Blastomycetes.—Kahane,[2] who was one of the first to describe the presence of blastomycetes in malignant tumors, in his last communication states that the blastomyces which he has constantly found in malignant growths is nothing more than the common yeast, Saccharomyces cerevisiæ, and he defines, tentatively, epithelioma (on which his statistics have chiefly been made) as the expression of a peculiar symbiosis of epithelial cells, leukocytes, and saccharomycetes.

Roncali[3] studied 5 sarcomata, in all of which he found blastomycetes that resembled each other very much and were similar to those described by Sanfelice, and by the author as occurring in adenocarcinoma of the ovary. They take the specific stain of blastomycetes, and resist the action of acids and alkalies like those found in the adenocarcinomas of the ovary. The parasites may be found within and without the cells, exceptionally also in the nucleus; they multiply by budding, and may in the early stages—*i. e.* when without membrane—possess an abundant chromatic protoplasm, or in the adult stage—*i. e.* with membrane—may have but little chromatic protoplasm or a protoplasm that has entirely lost the power of staining with the anilin dyes.

Sanfelice[4] has made inoculations into guinea-pigs of a yeast which he terms Saccharomyces ellipsoideus neoformans. Animals that had received an

[1] Centralbl. f. Bakt., Parasit. u. Infektionskrank., Feb. 28, 1896.
[2] Centralbl. f. Allg. Path. und Pathol. Anat., June 15, 1896.
[3] Centralbl. f. Bakt. und Parasit., Oct. 26, 1895.
[4] Zeit. f. Hyg. und Infektionskrank., 1896, i. p. 32.

inoculation into the subcutaneous tissue died on an average in 30 days. The inoculation was in a few days followed by a local swelling, which might or might not break down. The lymphatic glands of the groin and axilla also became enlarged. At the autopsy the tumor in the subcutaneous tissue was soft, not firmly adherent to the skin, and presented an appearance like that of the flesh of fish; the lymphatic glands had the same characters. The spleen was enlarged and was studded with elevated whitish nodules; the liver was but slightly increased in size, and rarely showed the whitish spots seen in the spleen. In the kidneys the nodules were more common than in the liver. The intestinal follicles and lymphatic glands were enlarged. The lungs were also enlarged and contained whitish areas. Brain, heart, and adrenals showed no macroscopic change. Guinea-pigs that were inoculated into the testicle died in the course of about 25 days. Testis and epididymis were enlarged and contained fish-flesh-like masses. Inoculation into the liver was followed by the development of tumors, single or multiple, in that organ. The changes were most marked after intraabdominal inoculations. A severe peritonitis, which the author terms a neoplastic one, was always noted. The viscera also presented nodules as previously described. The nodules contained enormous masses of blastomycetes. Many leukocytes containing blastomycetes were seen. Histologically the tumors consist of a network of young connective tissue in the meshes of which a variable number of cells resembling lymph-corpuscles is seen. Parasites are so abundant as to constitute the greater part of the nodules. The majority of parasites lie free, and vary in their tingibility. The enlargement of the lymph-glands depends more on the immense number of parasites present than on a proliferation of the cellular elements. The parasites could be demonstrated in nearly all the organs, but produced no reactive inflammation. The absence of epithelial hyperplasia in guinea-pigs is explained on the ground that death occurs too soon for it to take place.

The author then proceeds to point out the striking similarity between the appearance of the blastomyces in the tissues and the so-called coccidia described by many writers as occurring in the malignant tumors of man, and comes to the conclusion that the latter bodies are not protozoa, but blastomycetes—a view that had been already advanced by Russell. [While we do not wish to deny the validity of Sanfelice's conclusions, we feel that they are based on insufficient premises. We cannot see, for instance, why cultures which have so often been made from the malignant tumors were devoid of results, seeing that the blastomyces grow readily on all media. That some of the yeasts are pathogenic cannot longer be doubted, but the nature of the lesions produced is still far from clear. Rabinovitsch in no case was able to find tumor-like masses in the experimental animals such as Sanfelice describes. Nor did Busse find what could properly be called tumors. Further studies are needed to show that blastomycetes are the true cause of cancer.]

Sanfelice[1] describes another pathogenic blastomyces which was obtained from the lymphatic glands of an ox that had died of primary carcinoma of the liver,

[1] Centralbl. f. Bakt. u. Parasit., xviii. 17, 18, Nov. 9, 1895.

with metastasis to all the lymphatic structures of the body. The peculiar character of the parasites consisted in the presence of a calcareous, glassy degeneration. The parasite grows on artificial media, especially near the surface, and closely resembles the Saccharomyces neoformans previously described by the author. Guinea-pigs inoculated subcutaneously or intraperitoneally with cultures of the parasite died in about 2 months. The lymphatic glands were found to be enlarged, and the great omentum contained a number of hempseed-sized nodules; a few were also found on the spleen and lungs, and, microscopically, in liver and kidney. The new parasite responded to Sanfelice's special stain in the same manner as Saccharomyces neoformans. It therefore resembles the latter in every way, except that it is accompanied by a peculiar hyaline degeneration. Hence the author terms it *Saccharomyces litogenes* [lithogenes?]. The parasite is found in large numbers in the lymphatic glands, but yet not so abundantly as is the Saccharomyces neoformans in animals inoculated with it. The reaction of the tissues is marked, but the new cells resemble the fixed elements, and there is no inflammatory reaction. The degenerated blastomycetes are soluble in the mineral acids, without the escape of gas except in the case of nitric acid. The alkalies produce no changes. The parasite is also pathogenic for white rats, rabbits, sheep, cattle, etc.

In an extended communication on the same subject,[1] the author deals more exhaustively with the development of the study of pathogenic blastomycetes and with his experiments on Saccharomyces litogenes. In reference to the latter, the histologic changes produced in the organs of experimental animals are described, though not with great clearness. In the guinea-pig the nodules produced in the kidney, which organ is most affected, have not an inflammatory character, since the nuclei of the cells of which they are composed do not present the appearance of emigrated leukocytes. The cells of the straight and the convoluted tubules present no degenerative changes. Nodules are abundant in the lung, and here consist chiefly of proliferated cells derived from the interstitial tissue. This hyperplasia of the connective tissue brings about an almost total disappearance of the alveoli. In the liver the nodules consist of a connective-tissue stroma, containing many giant-cells and uninuclear cells resembling in part hepatic, in part lymphoid, cells. In several places in the newly-formed fibrous tissue many new bile-ducts are seen. In the midst of the new tissue calcareous masses are found, some of which still permit one to recognize the original elements. The longer the animal lived after inoculation the smaller was the number of blastomycetes found and the greater the reaction of the tissues. Mice die in about 8 days after inoculation. The deposit of lime-salts (probably the phosphates) is ascribed not to the parasite, but to the body-cells, which in that way seek to protect themselves against the blastomyces. In conclusion, the author remarks that it is not only important to study how a blastomyces normally behaves in the tissues, but also in what manner it degenerates, as otherwise it is easy to confound the stages of degeneration of blastomyces with those occurring in the surrounding tissues. It is

[1] Zeit. f. Hyg. u. Infektionskrank., xxi. 3, 1896.

obvious that those investigators who look upon all elements described as carcinoma-parasites as degeneration-products, are on the wrong track. A bibliography concludes the paper.

Sanfelice,[1] in another paper, presents the results of animal-inoculations with **Saccharomyces neoformans.** In 2 out of 30 dogs inoculation made into the posterior mammary glands was followed by the formation of a tumor in situ and multiple metastases in the internal organs. Of 8 roosters, 3 presented neoplasms.

Busse[2] makes a further report on the **pathogenic yeast** discovered by him. Inoculation in white mice is invariably fatal, death occurring in from 17 to 33 days. (This is much later than was the case originally, probably on account of a reduction in virulence through transplantation.) The invasion of the tissues produces chiefly degenerative changes, while inflammatory processes, although they occur, are slight. The presence of immense numbers of yeasts can produce enlargements simulating tumors. The yeasts from different organs of the same animal vary considerably morphologically. While admitting the possibility that the cell-enclosures in carcinoma and sarcoma are yeasts, the author cautions against haste in forming conclusions, as only cultivation can tell whether the enclosures are parasites and, if so, to what group of beings they belong.

Braithwaite,[3] by treating sections of carcinoma and sarcoma with liquor potassæ and mounting in Farrant's solution, found what he considers **a fungus** passing through four stages: 1. Spores; 2. Zygospores; 3. Spore-masses and spore-bags; 4. Mycelium emitted from the ruptured spore-bags. [The fact that a fungus was also found in fibrous and mucous polyps and in diabetes, renders it probable that the author, who is modest enough not to assert categorically that he has found the cause of malignant disease, is himself deceived.]

BACTERIOLOGY.

The Specificity of Bacteria.—Hansemann[4] attacks the almost universally accepted theory of the specificity of some of the best-known microorganisms, among others the Klebs-Löffler, the cholera-, and the tubercle-bacillus, which he considers as *nosoparasites* (Liebreich)—*i. e.* as organisms that are found in conjunction with a disease-process, which they are capable of modifying, but not of causing. He also denies that the diphtheria-serum is specific, on the ground that the Klebs-Löffler bacillus is not the cause of diphtheria. [We have not space to discuss this subject, but we believe that Hansemann, like Hypatia, is defending, with brilliant skill, a hopeless faith.]

Motility of Bacteria.—Hill,[5] in a series of experiments undertaken to determine the relation between the possession of motility by bacteria and their ability to penetrate wet cotton, obtained the following results: 1. Motile bacteria readily penetrate wet cotton in any direction, the rate of passage varying

[1] Zeit. f. Hyg. u. Infektionskrank., 1896, xxii. 1, p. 171.
[2] Virch. Arch., cxliv. p. 360.
[3] Lancet, June 29, 1895.
[4] Berl. klin. Woch., July 29, Aug. 5, 1895.
[5] Canad. Pract., July, 1895.

for different species with the relative activity of their motility; 2. Nonmotile bacteria pass *downward* through wet cotton readily; 3. Nonmotile forms *may* pass *upward* through wet cotton, but such passage is very slow—requiring from a few days to 2 or 3 weeks; 4. Aerobic forms which are also motile, may utilize their motility to resist gravitation, remaining thus at or near the surface of a liquid medium exposed to oxygen. The experiments were made with U-shaped tubes. It was also found that the method employed apparently afforded a means of separating the motile typhoid from the nonmotile colon-bacilli.

The Influence of the Electric Current on Bacteria.—Friedenthal[1] in a critical review of this subject comes to the conclusion that only by the aid of heat and the formation of antiseptic decomposition-products is the electric current capable of destroying bacteria. Whether the electric current exerts an influence when heat and electrolysis are excluded, is still questionable.

The Effect of the *X*-rays on Bacteria.—Mink[2] exposed agar-plates planted with typhoid-bacilli to the action of *x*-rays from a Hittorf's tube, the exposure lasting from 2 to 8 hours, but found that the exposed plates showed no noticeable difference in development from control plates. [As far as these experiments go, the Röntgen-rays seem to possess neither a germicidal nor an inhibitory action on bacteria.]

Concerning the Penetrability of the Intestinal Wall for Bacteria.—Neisser,[3] from experimental studies concludes, contrary to Nocard, Porcher, and Desoubry, that the chyle is normally perfectly sterile, and also proves that normally bacteria do not penetrate the intestinal wall; even the presence of grave intestinal lesions does not suffice for the passage of saprophytic or of pathogenic bacteria. The occurrence of general infection by way of the intestines must be looked upon as rare, and as dependent on special bacteria and peculiar conditions. The body is, therefore, not threatened by a greater danger from the intestines than from the skin or other mucous membranes.

Bacteria in Fluids and Organs of Healthy Individuals.—Ferranini[4] confirms the observations of Chauveau, Daslie, Galippe, and others to the effect that the blood and internal organs of healthy individuals may contain microorganisms. Ferranini assumes the existence of a sort of symbiosis between the body and the microbes, which remains physiologic as long as the latter do no damage to the former.

Bacteria on Money.—Vincent[5] made cultures from the surface of various pieces of money by rubbing the surface off with moist sterile cotton pledgets, and then transferring the latter to nutrient bouillon. When the coins were laid directly into the bouillon the latter remained usually perfectly sterile, even if the pieces of money were very dirty. From the bouillon gelatin-plates were made, also animal inoculations. The number of bacteria was greatest on the copper coins, least on those of silver. Bacillus subtilis

[5] Rev. d'Hyg., 1895, No. 8, ref. Centralb. f. Bakt. u. Infektionskrank., Dec. 10, 1895.

and B. megatherium were common, less so proteus vulgaris. Staphylococci and streptococci were also found. Tetanus-bacilli and tubercle-bacilli, as well as the bacillus of malignant edema, were observed in a few instances only. The comparatively small number of bacteria on coins is ascribed by the author to a strong bactericidal action of the metal.

The Fate of Microorganisms in Inspired Air.—Thomson and Hewlett[1] have calculated that 1400 organisms are inhaled into the nose every hour; in a London atmosphere, however, as many as 14,000 may pass into the nasal cavities during one hour's tranquil respiration. The fate of the thousands of microorganisms which thus enter the human body is a question of great pathologic interest, and this increases when it is remembered that the expired air is practically quite free from germs. The interior of the great majority of normal nasal cavities is perfectly aseptic. On the other hand, the vestibules of the nose, the vibrissæ lining them, and all crusts formed there are generally swarming with bacteria. This seems to demonstrate that the vibrissæ act as a filter. Not only does this arrangement arrest the ingress of germs, but those which have penetrated into the nose are rapidly ejected by the action of the ciliated epithelium. The nasal mucus, though not found bactericidal by the authors, distinctly inhibits the growth of germs. By means of a skilful device they succeeded in proving that practically all or nearly all the microorganisms of the air are arrested before reaching the nasopharynx; probably a majority are stopped by the vibrissæ at the very entrance of the nose, and those that do penetrate as far as the mucous membrane are rapidly eliminated. The nasal mucus is an unsuitable soil for the growth of organisms, and hence is an important factor in that it does not further their multiplication. The removal of the intruding organisms from the Schneiderian membrane is probably in the main due to the action of the ciliated epithelium, assisted by the trickling of mucus and the lacrimal secretion. Phagocytosis may share in the work of removal, though to a small extent, for the authors only once found phagocytic cells containing bacteria.

Suppuration With and Without Microorganisms.—Poliakoff,[2] after reviewing the relevant literature, according to which it appears still in doubt whether suppuration can be produced without microorganisms, details his own experiments, which had for their object the determination—1. Whether the introduction of substances such as turpentine and croton oil into dogs and rabbits, performed with strict antiseptic precautions, could produce suppuration; 2. How different species of animals behaved toward the same amount of such substances; 3. In what respects bacterial and nonbacterial suppuration differed; 4. How it was possible to produce for substances such as turpentine conditions of effect on the tissues resembling those obtaining in the elimination of toxins by bacteria. Regarding the first question, the results proved that substances such as turpentine and croton-oil, if introduced in sufficient quantity, can in rabbits produce suppuration; otherwise other forms of inflammation are produced. With respect to the third question, writers have heretofore held that

[1] Lancet, Jan. 11, 1896.

[2] Centralb. f. Bakt. u. Parasit., July 27, 1895.

bacterial suppuration possesses the following characteristics: (1) it tends to spread; (2) the pus consists of multinuclear cells; (3) the pus contains peptone. Nonbacterial suppuration has no tendency to spread; the pus consists of uninuclear elements, and contains no peptone. The author points out that, as far as the first characteristic is concerned, it is well known that bacterial suppuration does not always spread. As for the second, he found that the pus produced by chemic irritants contains both uninuclear and multinuclear cells; the pus obtained in dogs with turpentine consists almost exclusively of multinuclear elements. Finally, chemic tests to determine the third point showed the presence of peptone in both bacterial and nonbacterial pus. The fourth question was investigated by the following experiment: Capsules of celloidin, which are pervious, were prepared, filled with turpentine, sealed, and then dipped in turpentine. Into one rabbit the author introduced 5 drops of turpentine with a Pasteur pipet, into another a celloidin-capsule containing the same amount of turpentine. The second animal developed an abscess the size of a walnut, and containing free the celloidin-capsule, in which some turpentine still remained. The other animal only showed an infiltration, but no pus. In dogs a celloidin-capsule with 4 or 5 drops of turpentine produced a large abscess containing pus, blood, and shreds of tissue; peptone was also present in the pus. What is the cause why the same quantity of a substance in the one case (injection) produces merely inflammation, in the other (celloidin-capsule) suppuration? It can depend only on the constant elimination of minimal amounts of turpentine into the tissues in the latter case. Experiments with dead cultures of staphylococcus pyogenes aureus were made. One rabbit received 2 c.cm. of the culture by injection, another 6 or 7 drops in a celloidin-capsule. The second developed an abscess, the first presented no effects. The pus was sterile. From these experiments it follows that the constant and slow elimination of toxins into the tissues, as it occurs in nature, and as may be imitated by experiments, produces the reaction of the tissues which we term suppuration.

Chauffard and Ramond[1] report 2 fatal cases of **tetragenus-septicemia.**

Bulloch[2] gives an exhaustive resume of the literature bearing on the role of the **streptococcus pyogenes** in human pathology.

Yellow Fever.—Finlay[3] reports experimental studies on the tetracoccus versatilis, which he considers the cause of yellow fever.

Bacillus of Foot-and-mouth Disease.—Siegel,[4] whose researches on foot-and-mouth disease are well known, has been able to isolate the bacillus described by him as the cause of the disease from the intestinal contents of persons and animals affected. An inoculation-experiment with a pure culture into a hog seems to have been successful.

A Pathogenic Anaerobic Bacillus of the Intestine.—Klein,[5] from

[1] Arch. de Méd. expér. et d'Anat. path., May, 1896.

[2] Lancet, Apr. 11, 1896. [3] Edinb. Med. Jour., Dec., 1895.

[4] Arch. f. Laryng., Bd. iii., ref. in Centralbl. f. Bakt., Parasit. und Infektionskrank., May 23, 1896. [5] Centralbl. f. Bakt. u. Parasit., 1895, Dec. 23, No. 24.

the fecal discharges of persons attacked by an epidemic diarrhea that had suddenly broken out in St. Bartholomew's Hospital, London, isolated by means of anaerobic cultures a bacillus to which he applies the name bacillus enteritidis sporogenes. The bacillus is pathogenic for guinea-pigs, killing them in from 18 to 48 hours. The milk having been suspected as the cause of the epidemic, cultures were made by the author, and the same peculiar bacillus obtained as from the fecal discharges. Morphologically and culturally, the bacillus resembles the bacillus butyricus of Botkin, but the latter is nonpathogenic. The lesions produced in animals are similar to those caused by the bacillus of malignant edema.

New Capsule-bacillus.—Wright and Mallory[1] found at the autopsy on a man aged 40 a new capsule-bacillus in the pus of a bronchopneumonic focus. It differs from Friedländer's pneumobacillus, and is perhaps identical with one of the numerous capsule-bacilli already described. Hertfeld and Herrmann[2] describe a capsule-bacillus isolated from the pus of an alveolar abscess. It is actively motile, grows well on all media, is not pathogenic for animals, and is peculiarly sensitive to temperature, already ceasing to grow at 38° C.; it grows well at 30° C. The authors term it Bacillus capsulatus misothermus.

Chiari[3] describes a case of pyemia in which he found a capsule-bacillus differing from the hitherto known species. The patient, who had died after a short illness, presented a large series of lesions: suppurative nephritis, prostatitis and cystitis, endocarditis, splenic infarcts, otitis media, and meningitis. In all of these foci the same bacillus was present, the biologic features of which we can only briefly state: Pathogenic for all laboratory-animals, not staining by Gram's method, and forming gas in sugar-glycerol-agar. It differs in a number of points from the pneumobacillus of Friedländer. The primary lesion, the author believes, was in the urogenital apparatus, the cystitis being the first phenomenon.

Bacillus of Hemorrhagic Purpura.—Finkelstein[4] reports a case of hemorrhagic diathesis in a boy aged 8 days. In the organs he found a specific bacillus which kills mice by septicemia, and in rabbits, when introduced intraperitoneally, produces invariably a typical hemorrhagic diathesis, and thus deserves to be considered the cause of the disease in the boy. The organism, a plump, short bacillus with rounded ends, corresponds in its pathogenic behavior toward mice and rabbits with the bacillus hæmorrhagicus of Kolb, which the latter considers the cause of idiopathic purpura.

Microorganism in Chancroid.—Ducrey[5] believes that the streptobacillus observed by him is the cause of chancroid, although he has not yet succeeded in cultivating it artificially. By means of a series of inoculations he finally obtained an ulcer in which the streptobacillus was the only organism present. He looks upon this as a pure culture in the living tissues.

[5] Monatsh. f. Prakt. Dermat., Bd. xxi. No. 2.

Organism resembling the Bacillus of Glanders.—Kutscher[1] isolated a microorganism closely resembling the bacillus of glanders from the body of a guinea-pig inoculated with the nasal secretion of a horse suspected to be glandered. This bacillus produces a white growth on potato, and stains by Gram's method. Injected into the peritoneal cavity of guinea-pigs, it causes Straus's glanders-reaction,[2] and thus renders this reaction valueless as a specific differential sign of the glanders-bacillus. Kutscher classes the bacillus with the group producing pseudotuberculosis.

TUBERCULOSIS.

Tubercle-bacilli in the Blood of New-born Infants.—Bar and Renon[3] injected into animals the blood from the placental end of the umbilical vein of 5 children, the mothers of which were tuberculous, and obtained positive results in 2.

Effect of Sunlight on the Tubercle-bacillus.—Migneco[4] placed tuberculous sputum on pieces of linen and other material and exposed them to the direct sunlight. He found that the tubercle-bacilli were killed in from 24 to 30 hours, their virulence being reduced in from 10 to 15 hours.

Tuberculosis of the Alveolar Processes.—Zaudy[5] in an exhaustive article on this subject states that the bacilli enter between the gum and the tooth; caries acts as a predisposing cause. The disease is most common between 15 and 50, and is more frequent in the male sex (23 men in 37 cases).

Tuberculous Cervical Glands and Carious Teeth.—Starck[6] found in 113 children having enlarged glands 41 % with carious teeth, the glandular enlargement corresponding nearly always with the position of the carious teeth. In 3 children with tuberculous glands carious teeth were found, but tubercle-bacilli could not be demonstrated in them. In a youth of 18 with tuberculous glands on both sides of the neck, tubercle-bacilli were found in two molar teeth of the left lower jaw. As, however, the grandular tuberculosis was bilateral, and as pulmonary tuberculosis was present, the case is somewhat equivocal. In a young girl of 14, otherwise healthy, the author found in a molar tooth with a carious cavity a tuberculous granulation-tissue at the bottom, and glandular tuberculosis on the same side only. This observation seems to point to a connection between the glandular tuberculosis and the carious tooth, with the reservation that an actual tuberculous process existed at the point of entrance of the bacilli. [The care of the teeth and other hygienic measures, to which the author also refers, take on renewed importance from these studies, especially when we consider the researches of Zaudy on tuberculosis of the alveolar processes. They should inculcate upon dentists the importance of the thorough sterilization of their instruments.]

Tuberculosis of Mammary Gland.—Gaudier and Péraire[1] report 3 new cases of tuberculosis of the mammary gland.

Goldmann[2] reports a case, the first of its kind, of primary **tuberculosis of the tunica vaginalis testis.**

Tuberculosis in Early Childhood.—Kossel[3] reports 22 cases of tuberculosis in children, ranging from 2 months to 5 years, studied antemortem and postmortem; tuberculous foci were also found in 14 children that had died of other diseases—10 times in the bronchial and 4 times in the mesenteric glands. In none of the 14 had the tuberculous lesions caused any symptoms. The lesions in the whole series were most marked in the respiratory tract and the lymphatic glands belonging to it, secondly in the digestive tract. In one case only was the lesion confined to the intestinal tract of a child 8 months old, presenting an ulcer in the ileum and tuberculosis of the mesenteric glands. General or partial disseminated tuberculosis of the lung was the most frequent lesion. In the more chronic cases lobular and more extensive caseous pneumonias were added. In the hepatized portions it was always possible to demonstrate the presence of other microorganisms, especially streptococci and influenza-bacilli, the former occurring especially in cases of gelatinous infiltration, the latter in those in which the bronchopneumonia was associated with a purulent bronchitis and bronchiolitis. In one instance the influenza-bacillus had caused a fibrinous bronchitis. In one case the tuberculous process assumed the form of a cheesy tumor occupying the upper and middle lobes of one lung. The bronchial glands were affected in the majority of cases, in all but 2 apparently before the lung. In 9 cases the mesenteric glands were affected. The intestine was involved but twice. In 15 cases there was a general dissemination of the tuberculosis over the entire body. This tendency in children to general miliary tuberculosis is probably the reason why one rarely observes such extensive local destruction in the lung as in adults. The author, despite careful scrutiny, was not able to find the point of entrance of the bacilli into the circulation. Taking up the question how infants of but a few months of age become infected with tuberculosis, Kossel admits the possibility of hereditary transmission, which cannot be doubted since Birch-Hirschfeld's case, but believes that the vast majority of cases are infected after birth from contact with tuberculous persons.

Regarding the diagnosis, we may add, in this place, that the author succeeded in several instances in finding the tubercle-bacillus in the feces. [We would point out the overwhelming preponderance of the lesions of the respiratory tract in view of the widespread belief that the lungs are not as frequently affected in children as in adults. There can be no doubt that the view of the postnatal origin of tuberculosis is the correct one, though the possibility of a direct hereditary transmission is undeniable. As soon as we recognize the contagiousness of tuberculosis, as we sooner or later must, the ways of limiting its ravages become clear.]

[2] Beit. z. klin. Chir., xiii. H. 2.

[3] Zeit. f. Hyg. u. Infektionskrank., 1896, i. p. 59.

Typhoid Fever.—Elsner[1] found that the addition of **potassium iodid** to an acid culture-medium was one of the most valuable **means of separating the typhoid-bacillus from the bacillus coli communis.** The medium is prepared by boiling gelatin with a potato-infusion (0.5 K. to 1 liter water), and then obtaining a proper degree of acidity, as recommended by Holz,[2] filtering, and sterilizing. The gelatin is placed into Erlenmeyer's flasks and receives 1% of potassium iodid. The culture is then inoculated and poured into plates. On this medium practically only the bacillus coli and the typhoid-bacillus will grow, but—and this is the important advantage of the method—the two organisms present different appearances. The typhoid-bacilli, namely, remain far behind the others in growth, being after 24 hours scarcely or not at all visible under a low magnification, while the colon-bacilli are fully grown at this time. After 48 hours the typhoid colonies appear as small, shining, very finely-granular colonies, resembling drops of water, the colon colonies being larger, more coarsely granular, and brown. On the dilution-plates a confounding of the two is impossible. The method also proves useful in isolating typhoid-bacillus from drinking water and feces. Even when the dilution was 1 : 8000 millions the bacilli could yet be demonstrated. In feces the bacilli were found as early as the 7th day and as late as the 6th week. [If further investigations prove what Elsner with apparently good reason claims for this method, the diagnosis of typhoid fever can be made in an early period of the disease, and, should a practically useful antitoxin be obtained, the treatment at once instituted.]

Bacteriologic Examinations of the Blood in Typhoid Fever.—Thiemich,[3] after reviewing the literature of this subject, details his studies made on 7 cases (6 of his own). The blood was taken in part from the rose-red spots, in part by means of a Pravaz syringe from a vein at the elbow, and transferred to fluid agar. In 3 cases the typhoid-bacillus was found in the spots, and once in the blood from the vein. In one case bacteria were absent; in the others, staphylococci resembling staphylococcus pyogenes albus were found. These, however, were not virulent, and may have been only epiphytes, although similar organisms were found in 2 fatal cases in the mesenteric glands, and once in the spleen. The author also tried to determine whether the bactericidal effect of the blood on the typhoid-bacillus is so prompt as to lessen the value of bacteriologic examination. He found, however, that the blood of a healthy man has no appreciable influence within 2 minutes, which is a greater time than usually was consumed from the withdrawal of the blood to its inoculation on nutrient agar.

Teissier[4] found typhoid-bacilli in the blood obtained from a vein of the

[1] Zeit. f. Hyg. u. Infektionskrank., 1896, H. 1, p. 25.

[2] Zeit. f. Path., 1889, Bd. xiii. To neutralize 10 c.c. gelatin, 2.5–3.0 c.c. of a decinormal sodium hydrate solution are required. Litmus-tincture serves as indicator. Sufficient alkali is added before filtration that the liquid reacts only slightly acid. During the sterilization the acidity increases. The reaction should always be tested after sterilizing.

[3] Deutsch. med. Woch., 1895, No. 34.

[4] Arch. de Méd. expér. et d'Anat. path., Sept. 1, 1895.

forearm in a case of typhoid fever on the sixteenth day of the disease. The bacilli were demonstrable only by cultures, not on cover-slips. The author believes that the presence of the bacillus in the blood may to a certain extent explain the determination of the arteritis or phlebitis usually considered secondary infections or due to the toxins of the typhoid-bacillus.

Septicopyæmia Typhosa.—Kühnau[1] reports the case of a pregnant woman, aged 32, whose illness began with malaise, fever setting in a few days later; labor occurred without complication. The patient, however, developed tympanites, diarrhea, roseola, enlargement of spleen, hypoleukocytosis, and albuminuria, and finally facial erysipelas. Decubitus and erysipelas of lumbar and gluteal regions preceded death. In the blood, during life, the author found typhoid-bacilli. At the autopsy the intestinal tract was found perfectly normal; the mesenteric glands were enlarged and in part necrotic; the kidneys contained minute abscesses; the right spermatic vein was thrombosed and presented, under the microscope, periphlebitic changes. From the mesenteric glands, the renal abscesses, the thrombi of the left spermatic vein, and the spleen the author succeeded in isolating the typhoid-bacillus. The case is one of typhoid septicopyemia. Whether the bacilli entered through the endometrium or through the intestines without producing there the primary lesion, as in the cases reported by Banti, Chantemesse, Adénot, Balp, Fernet, and others, the author is unable to decide. [The fact that the patient felt ill 6 days before her labor, and had some fever, would point to another place of entrance of the disease than the uterus. The enlargement of the mesenteric glands, as the author says, cannot be taken as positive evidence of intestinal infection, yet its presence strengthens the latter theory.]

Typhoid-bacilli in the Urine.—Wright and Semple[2] found typhoid bacilli in the urine in 6 out of 7 cases of typhoid fever. They agree with Wathelet and Sanarelli that typhoid fever is originally a blood-infection, and in view of the recent investigations (see *Year-Book* for 1896, p. 996) proving the absence of the bacilli from the feces, hold that while the latter may be disinfected as a precautionary measure, special attention should be bestowed on the disinfection of the urine. In every doubtful case, also, the bacteriologic examination of the urine should not be neglected.

Singer[3] found typhoid-bacilli in the urine of a case of typhoid fever.

Colon-bacillus in the Urine of a Typhoid-fever Patient.—Ljubomudroff[4] reports a case of typhoid fever in which blood and pure cultures of the colon-bacillus were excreted in the urine.

The Lymphoid Nodules of the Liver in Typhoid Fever.—Reed[5] discusses the nature of the so-called lymphoid nodules of the liver in typhoid fever. His conclusions, in part based on experiments on rabbits, are as follows: 1. The term "lymphoid nodule," by which these localized lesions of

[1] Berl. klin. Woch., July 27, 1896.
[2] Lancet, July 27, 1895.
[3] Wien. klin. Woch., 1896, May 14.
[4] Centralbl. f. Bakt. u. Parasit., 1895, Dec. 23, No. 24.
[5] Am. Jour. Med. Sci., Nov., 1895.

the liver in typhoid fever have been heretofore generally designated, is an improper one, since it expresses an erroneous idea as to the origin of these peculiar formations; 2. These so-called lymphomata are not composed of lymphoid cells which have wandered in from the portal vessels, but represent well-defined areas of cell-death; 3. In the earlier stages of the necrosis the nuclei which are found in such abundance in these areas are not the nuclei of lymphoid cells, nor do they arise from the multiplication of the nuclei of the hepatic cells, but owe their origin in small part to the disintegration of the nuclei of the liver-cells involved, and in greater part to the presence of multinuclear leukocytes which have wandered into the necrotic area; 4. At a later stage of the process, when the liver-cells have become quite broken down into granular detritus, the numerous nuclei which are observed along the margins of the area or are seen to have penetrated into its center are those derived from the connective-tissue stroma of the organ; 5. Thus it is probable that the areas of necrosis are replaced by well-defined areas of localized connective tissue; 6. Necrotic areas, resembling in all respects those found in the human liver in typhoid fever, can be reproduced experimentally in the rabbit's liver by the injection into the mesenteric vein of a pure culture of the typhoid-bacillus; 7. Although these areas of necrosis in the liver owe their origin to the action of the typhoid-bacillus, it has not been possible more definitely to determine in what way this cell-death is brought about; that is to say, whether it is due to the immediate presence of the bacilli within the areas of necrosis,

FIG. 124.—A necrotic area of the human liver in typhoid fever. The area of necrosis entirely surrounds the central vein of the lobule; the cells have lost their nuclei, but still retain their continuity with the healthy cells (Am. Jour. Med. Sci., Nov., 1895).

or is caused by the action of the so-called toxalbumins assumed to be present in the general circulation. The latter explanation would seem the more probable, since it is possible to produce well-defined areas of necrosis in the liver of guinea-pigs by the injection of toxalbumins alone, as has been done in

diphtheria, and by minute injections of ricin and abrin. [The sections were stained with Löffler's methylene-blue and eosin; the latter has a selective affinity for the degenerated areas. The illustrations (Figs. 124, 125) show well the microscopic appearances.]

FIG. 125.—Later stage or necrotic area of human liver in typhoid fever. The cells have entirely lost their shape; many small round nuclei within area *a*, and here and there a few spindle-cells (*b*) (Am. Jour. Med. Sci., Nov., 1895).

The Colon-bacillus.—Theobald Smith[1] calls attention to the behavior of bacillus coli and related forms in fermentation-tubes containing sugar-bouillon as a means of differentiation. The following points should be taken into consideration: 1. The evolution of gas, as to (*a*) total quantity, (*b*) rate of accumulation, (*c*) approximate composition, (*d*) temperature most favorable; 2. Formation of acids; 3. Behavior toward different carbohydrates. In the application of the test with bouillon containing carbohydrates other than the most easily attacked glucose or dextrose a difficulty arises. Most beef (and the flesh of other animals as well) contains a fermentescible substance acting like dextrose. In testing with dextrose this does not interfere. When, however, other sugars are to be employed, only that bouillon should be used in which gas does not appear during the multiplication of some gas-producing bacterium. The dextrose-free beef the author encountered in about one-fifth of the beef purchased. Recently he found the flesh from cattle in advanced stages of tuberculosis, those that show signs of emaciation, free from sugar. Such bouillon should be set aside and used only with saccharose, lactose, or other sugars, excluding dextrose. Beef placed in boiling water immediately after slaughter has also been found free from fermentescible substances.

The author then discusses the characters of the colon-group of bacilli, the presence of which in water he considers a valuable indication of pollution. He also points out the fundamental difference between B. coli on the one hand and the large hog-cholera group (including B. enteriditis and B. typhi murium) and the typhoid-bacillus on the other.

[1] Am. Jour. Med. Sci., Sept., 1895.

In another section the author discusses the methods of isolating B. coli from water. The two adopted by him are based on that by Rodet and G. Roux, and by Vincent: To flasks of bouillon containing about 100 c.cm. 50 c.cm. of water were added, the mixture quickly warmed and placed at 37° C. After 16 to 24 hours gelatin-plates were made, and rarely more than one species found. When membranes appeared on the bouillon the flask was tilted and the fluid for the plates taken from the deeper layers. By this precaution B. subtilis and other liquefying bacilli were avoided. Phenol was not added to the bouillon. The other similar process consisted in adding a small quantity of water to each one of a series of fermentation-tubes containing glucose-bouillon and placing them in the thermostat. The amount of water added depended on the probable amount of pollution, and varied from 0.1 to 1, or even more, c.cm. If after 2 or 3 days any tube indicated the presence of B. coli by the quantity of gas formed and the rate of evolution, plates were made from the deposit. Usually but one species, B. coli, appeared; sometimes two were found on the plates.

Grimberg[1] found the **colon-bacillus in the mouths of healthy persons.** It was found in 45% of the cases examined, and chiefly on the tonsils. Next in frequency was the staphylococcus aureus.

DIPHTHERIA.

Ascitic Fluid as a Culture-medium for the Diphtheria-bacillus.—V. Dungern[2] has found that the addition of ascitic fluid to the culture-medium increases the virulence of the diphtheria-bacillus.

Tenacity of Diphtheria-bacillus.—Aaser[3] found that disinfection of the room of the barracks occupied by a diphtheria-patient, together with sterilization of the clothing by means of steam at 110° C., did not check the spread of the disease. A bacteriologic examination of the throats of the soldiers in the barracks (89) was made: 17 tubes presented a growth of virulent diphtheria-bacilli. This discovery gave the clue to the spread of the disease. The 17 suspected cases were isolated: 1 developed diphtheria, 2 had a throat affection resembling lacunar angina; the others remained well, but the mucous membrane of the fauces was much reddened, and this did not disappear until the Klebs-Löffler bacilli could no longer be detected on culture of the mucus from the tonsils. In the same hospital in which the soldiers were isolated diphtheria developed in a convalescent patient in the scarlet-fever ward. Cultures from the throats of all the children showed that 20% harbored virulent diphtheria-bacilli in their throats. One of the children, in which the bacilli had been found on Oct. 6 and again on Oct. 31, no membranes having developed in the mean time, was sent home Nov. 2, with very few bacilli in the mucus of the tonsils. On Nov. 6 two younger sisters of the child were brought to the hospital with diphtheria, and no other mode of

[1] La Progrès méd., 1895, No. 43, p. 263.
[2] Centralbl. f. Bakt., Parasit. u. Infektionskrank., Feb. 5, 1896.
[3] Deutsch. med. Woch., 1895, No. 22, p. 357.

infection than the child dismissed Nov. 2 could be traced. From these observations the author concludes that the germs of the disease were transported by persons, and not by clothes or other articles. Another interesting fact is that one of the isolated cavalrymen, who had no membrane in the throat, developed a well-marked, diphtheric paralysis of accommodation, which, the author believes, was due to the production of a certain amount of toxin which was absorbed. [These observations show the importance of isolating a patient convalescent from diphtheria as long as the presence of bacilli can be demonstrated by culture. In some cases, as we ourselves have experienced, it may become difficult to resist the demands of the parents, who, seeing no longer any membrane in the throat, press the physician to have the quarantine removed. But there can be no doubt either of the duty or the wisdom to continue isolation until the culture-test is negative.]

Bacteriologic Examination of Fatal Cases treated with Antitoxin.—Stokes[1] bacteriologically examined 9 fatal cases of diphtheria in which antitoxin had been used. The following are the results: In all of the cases the bacillus diphtheriæ was found postmortem in cultures from the respiratory tract. In 8 of the 9 cases there was a well-marked invasion of the blood by pyogenic cocci. In 5 cases the streptococcus was found in the liver, spleen, kidney, and blood of the heart; in 1 case in the kidney and blood of the heart, and in 1 case in the spleen. The pneumococcus was found in 2 cases in the kidney, in one of which the streptococcus was also found in the spleen. In the cultures from 1 case the only organism present was the bacillus coli communis. In the lungs of all these cases the bacillus diphtheriæ, streptococci, pneumococci, and the staphylococcus pyogenes aureus were found, either alone or in various combinations. The presence of mixed infection probably explains the fatal issue in spite of the use of antitoxin, for this cannot act against other organisms than the bacillus of diphtheria. As to the occurrence of the latter in the internal organs in these 9 cases, it was found in the kidney in 4 cases, and once in the heart and spleen respectively.

Influenza.—Nasstiukoff[2] accepts Pfeiffer's bacillus as the cause of influenza, and proposes a stain which is better than Löffler's solution or dilute carbol-fushsin recommended by Pfeiffer. The stain is prepared by adding to a saturated solution of the anilin dye (in absolute alcohol) a sublimate solution instead of distilled water. The author mixes 1 : 2000 sublimate solution (containing, for better solution of the $HgCl_2$, a little ammonium chlorid) with a few drops of anilin oil, and after agitation filters. The clear filtrate is added to the alcoholic solution of the dye. This mixture stains in a few seconds. Although not stained by Gram's method, they are not decolorized by Lugol's solution after having been stained by this mixture.

Pfeiffer had not succeeded in making plate-cultures of the influenza-bacillus. As blood is the best medium for the organism, the author believed that egg-

[1] Boston M. and S. Jour., Dec. 12, 1895.

[2] Etiology and Clinical Bacteriology of Influenza, Inaug. Dissert., St. Petersburg, 1894 (Russian); ref. in Centralbl. f. Bakt., Parasit. u. Infektionskrank., Apr. 8, 1896.

yolk, which chemically (in its animal constituents) closely resembles blood, might be serviceable. The yolk was dissolved in a 10% solution of NaCl, in which solution the vitellin is insoluble. A 2% agar-solution was then prepared. If the two are mixed at 50° C., the coagulation of the albumin can be prevented. The mixture must be at once poured into test-tubes, which are sterilized by Tyndal's method. On this medium the author succeeded in making plate-cultures of the bacillus and obtaining it pure.

In his clinical studies the author came to the conclusion that the bacteriologic examination of the sputum was sufficient for purposes of diagnosis. Inoculations of pure cultures into animals proved that the bacillus is pathogenic; healthy animals recovered; those weakened by other diseases succumbed sooner or later, which confirms the clinical observations in man.

CHOLERA.

Differential Diagnosis between Cholera-vibrios and other Vibrios.—Dunbar[1] has carefully applied Pfeiffer's reaction to various vibrios obtained from intestinal discharges and drinking-water. In order that the reaction be specific the following postulates must be fulfilled: 1. All vibrios recognized as true cholera-vibrios must react positively to the serum; 2. A given culture must react to a given serum at all times in the same manner; 3. The serum of animals immunized against cholera-vibrios, no matter what their origin, must always act upon true cholera-cultures, while it should not influence other cultures. Conversely, a serum obtained through cultures that did not react against true cholera-serum should not act upon true cholera-cultures; and 4. The cholera-cultures used for the experiments should be virulent or easily rendered so. From experiments based on these postulates the author concludes that Pfeiffer's reaction is to be considered specific, although caution should be exercised in positively pronouncing as cholera-vibrios all vibrios reacting to the cholera-serum. This is particularly true when the serum of immunized goats is used, for the latter seems to possess both a specific and a nonspecific bactericidal power, and transforms certain phosphorescent bacteria into granules, while the serum of guinea-pigs immunized to cholera does not do so.

Wiener[2] has succeeded in producing a general **infection of young cats by the administration of cholera-vibrios** by the mouth. The reaction of the gastric contents was in all animals strongly acid; sometimes also that of the upper portion of the intestines.

The same author[3] has repeated the experiments of Metschnikoff on the **influence of various species of bacteria on the cholera-vibrio.** Metschnikoff had shown that B. coli and some other organisms favored, and B. pyocyaneus retarded, the growth of the cholera-vibrio on gelatin-plates; furthermore, young animals inoculated by the mouth with cholera-vibrio and

[1] Zeit. f. Hyg. u. Infektionskrank., 1896, ii. p. 295.
[2] Centralbl. f. Bakt., Parasit. u. Infektionskrank., Feb. 21, 1896.
[3] Ibid., May 8, 1896.

B. coli died more promptly than those receiving the vibrio alone. The author's results seem to confirm those of Metschnikoff. The addition of B. pyocyaneus to the cholera-cultures lessened the virulence of the latter.

The Gonococcus.—Steinschneider and Schaefer[1] draw the following conclusions from an experimental study of the biologic properties of the gonococcus: 1. The best medium is blood-serum or serous fluid of man, but the serum of the ox, sheep, dog, or rabbit may be substituted; these media are indispensable. 2. Urine-agar has not proved a reliable medium in their experience. 3. In Wertheim's plate method a sterile camel's-hair brush may be profitably substituted for the platinum-loop in spreading the pus over the surface of the serum-agar plates. 4. Exposure to a temperature of 40° C. for 12 hours or more not only inhibits the growth, but destroys the vitality of the organism. 5. When exposed to room-temperature for not too long a period, growth is inhibited, but not destroyed. 6. When gonorrheal pus is mixed with water or urine, gonococci may retain their vitality for from 1 to 2 hours, under favorable conditions even longer. 7. When introduced into the subcutaneous connective tissue the gonococci do not produce suppuration. Chadwick[2] could not confirm Turro's investigations (see *Year-Book* for 1896, p. 1000), and concludes (1) that the gonococcus does not grow on acid media; (2) that the gonococcus of Neisser undoubtedly causes true gonorrhea, but to make a certain diagnosis of this organism it must be found in considerable numbers and arranged in groups within the leukocytes. It must also decolorize very readily by Gram's method of staining. Hammer[3] employs albuminous urine for the cultivation of the gonococcus.

The Gonococcus as Cause of Pyemic Abscesses.—Bujwid[4] describes the case of a man, aged 32 years, suffering from gonorrhea, who 2 days after catheterization was seized with a chill, which repeated itself several times in the next 10 days. Four abscesses formed, all intramuscular, in various parts of the body, from the pus of which gonococci were cultivated on serum-agar. This proves that the gonococcus can cause pyemic processes.

Studies in Pathogenic Yeasts.—The class of hyphomycetes having been proved to possess pathogenic species, it was to be expected that disease-producing saccharomycetes should exist. Busse[5] isolated a species of yeast from a human subject suffering from a disease resembling chronic pyemia and characterized by suppurative changes in the skin, cornea, bones, spleen, and kidneys. Pure cultures injected into animals produced usually only local suppuration, but were fatal to white mice, in the blood of which the organism could be demonstrated. Colpe and Sanfelice have also found pathogenic saccharomyces, the former in a case of chronic cervical endometritis. Rabinowitsch[6] made a careful study of 50 varieties of wild yeasts, and found 7 that were pathogenic to lower animals. Experiments with cultivated yeasts were

negative. All of the pathogenic forms were harmless to guinea-pigs, but invariably fatal to mice, and at times also to rabbits. As they were, as a rule, demonstrable in large numbers in the blood and internal organs, it may be assumed that they acted through infection and not through intoxication. Tumors were never produced in the experimental animals. Yeasts could readily be found in the tissues, usually between the cells, sometimes within them. The yeast-cells are easily stained with all anilin dyes, a weak Ziehl's or methylene-blue solution being especially useful. Very clear pictures are given by Gram's method.

Immunity; Toxins and Antitoxins.—Gruber and Durham[1] have made a series of valuable observations bearing on the question of immunity, of which we give the conclusions: 1. Guinea-pigs can be rendered immune for a long period of time by the intraperitoneal introduction of dead or nearly nonpoisonous cultures of cholera-, typhoid-, or colon-bacillus. The bacterial bodies are not in themselves poisonous; the immunizing constituents of the bodies of bacteria are different from the bacterial poisons; 2. The immunity thus produced is a true immunity against infection, not against the toxins. This does not exclude the possibility of the production of an immunity against the latter in some other way; 3. The destruction of bacteria in the immunized animal is produced, as Pfeiffer has shown, under the influence of the body-juices. The multinuclear phagocytes play only an unimportant role in the phenomenon; 4. The "antibodies" are contained in the blood and fluids of immunized animals in active form; 5. They act in the actively and passively immunized animal exactly as they act upon the bacteria outside the animal body; 6. The "antibodies," the characteristic constituents of the blood and tissue-juices of the immune animal, have directly nothing to do with the killing of the bacteria; 7. The death of the bacteria is brought about by the alexins of Buchner, which are always present in the body-fluids and are not specific; 8. The chief effect of the antibodies is to cause a swelling of the envelopes surrounding the bacterial bodies. This is shown by the bacteria becoming glabrous, by a tendency on their part to unite in large globular masses, and by a loss of motility. On account of this fundamental action of the antibodies, Gruber terms them *glabrificins;* 9. By causing the bacteria to swell, the glabrificins render them amenable to the action of the alexins, through which their death is brought about; 10. In this process the glabrificins are used up; 11. Active and passive immunity are in their nature identical; both depend on the presence of glabrificins in the body-fluids; 12. There is no active immunity without the presence of glabrificins in the body-fluids; 13. The discovery that active immunity persists even after the antibodies have entirely disappeared from the body-fluids together with the power to confer passive immunity, depends on the fact that in the course of time the glabrificins lose their concentration to such a degree that the quantity contained in the dose of serum employed for conferring passive immunity is insufficient; 14. The presence of glabrificins in immunized animals could be demonstrated

[1] Münch. med. Woch., 1896, p. 206.

as late as 13 months after the last immunization; 15. The glabrificins are specifically different; every species of bacteria corresponds to a specific glabrificin; 16. Their action, however, is not specifically limited, but only differs in degree, every glabrificin acting most powerfully against its own species of bacteria; on other bacteria the action is the more marked the more related the bacterium is to the species; 18. The glabrificins are undoubtedly derivatives of the bacterial bodies (of specific proteins?), but are only formed in the immunized animal by some modification (combination with constituents of the infected organism?). The place of their formation is probably the macrophages, which eventually englobe the multinuclear leukocytes that are laden with bacterial products; 19. All the facts given apply only to cholera, typhoid, and related processes. In diphtheria- and tetanus-immunity the conditions seem to be materially different.

Heredity of Acquired Immunity.—Vaillard[1] from an experimental study comes to these conclusions: (1) The mother alone is capable of transmitting immunity to the descendants; (2) the father never transmits it; (3) the immunity received is of short duration, and disappears during the first months of life. The immunity of the offspring depends upon the action of the maternal plasma upon the fetal tissues.

Alkalinity and Immunity.—Calabrese[2] from a study of the influence of the alkalinity of the blood on immunity concludes that the alkalinity of the blood is a most powerful and constant means of defence of the immunized organism.

Protective Substances in the Blood of New-born Infants.—Fischl and v. Wunschheim[3] from an experimental study of the protective power of the blood of infants against infectious diseases conclude as follows: 1. The blood-serum of the new-born infant exerts no bactericidal influence upon the diphtheria-bacillus; 2. The blood-serum of the new-born infant does not attenuate the virulence of diphtheria-bacilli; 3. The blood-serum of the new-born is capable of preventing, in the great majority of cases, death from diphtheria in susceptible animals receiving separate injections of diphtheria-cultures and the serum in corresponding doses; 4. The blood-serum of the new-born is also capable of protecting, by separate injections of proper doses, guinea-pigs against the diphtheria-toxin; 5. By ascending doses of serum the percentage of recoveries from the effects of infection and intoxication is increased and convalescence shortened in time; 6. The injection of a mixture of toxin and serum under the skin of the abdomen of guinea-pigs produces no symptoms of disease in some cases, but in the greater number the animals die with typical appearances of intoxication; 7. Whether the result just described depends upon the irregularity of action of mixtures of the serum and toxin, or upon other accidental or unknown conditions, future experiments must show; 8. The greatest protective strength of the blood-serum of the new-born infant is the same as Wassermann found for the adult (one-twentieth

[1] Ann. de l'Inst. Pasteur, Feb., 1896.

[2] Il Policlinico, Feb. 15, 1896.

[3] Zeit. f. Heilk., 1895, Bd. xvi. p. 429; Prag. med. Woch., 1895, Nos. 45–51.

normal unit per c.c.), and the frequency of the occurrence of protective substances in the blood of the new-born is in the same ratio as that found by Wassermann for the adult; 9. That the protection manifested by the serum is not a *general peculiarity* of the serum is shown by the negative experiments in which the same quantities of serum were used; 10. In what manner the activity of the serum manifests itself in the animal body cannot be explained with our present knowledge.

Heating the serum to 55° C. did not destroy the protective bodies; hence these cannot be alexins, but resemble in their resistance to heat the specific antitoxins. As far as the age of the mother influenced the immunity of the child, it seemed that the best conditions prevailed between 21 and 25. The second and third births presented the highest percentage of protective bodies.

The Specific Immunity-reaction of the Typhoid-bacillus.—Pfeiffer and Kolle[1] from a carefully conducted series of experiments which it is not necessary to give in this place draw the following conclusions: 1. The serum of patients convalescent from typhoid fever contains substances which in minute doses are bactericidal against living typhoid-bacilli in the body of the guinea-pig, and dissolve them. The bactericidal action of the serum cannot be explained by the presence in it of a preformed bactericidal substance, but it is to be assumed that the introduction of serum into the guinea-pig produces a reaction in the animal's organism whereby the inactive "antibodies" present in the serum are transformed into an active specifically bactericidal modification. 2. Antitoxic substances are not demonstrable in the serum of convalescents from typhoid fever. 3. The serum of normal individuals, as well as that of persons suffering from a variety of diseases, possesses a certain influence against the intraperitoneal typhoid infection of guinea-pigs, but there is both a quantitative and a qualitative difference between normal serum and serum of convalescents from typhoid fever. The quantitative difference consists in that from 20 to 100 times the amount of normal serum is necessary to produce the same result; the qualitative, in that the normal serum possesses no specific action. 4. The action of the bactericidal substance of the serum of convalescents from typhoid fever is, on the other hand, a specific one—*i. e.* it is limited to the bacillus typhosus, and does not extend to bacteria resembling it. It can therefore be employed for the differentiation of the true typhoid-bacillus and its congeners. Moreover, the specific blood-changes can be used for the late diagnosis of a past typhoid process in convalescents. 5. The demonstration of specific bactericidal substances in the serum of convalescents from typhoid fever proves anew the sole etiologic role of the typhoid-bacillus in human typhoid fever and its specificity. 6. In the serum of goats immunized with ascending doses of living or dead typhoid-bacilli the same specific bactericidal substances are present as in the serum of convalescents from typhoid, but the quantity is too small to be therapeutically useful. 7. Antitoxic substances could not be found in the serum of immunized goats.

Specific Protective Bodies in the Blood of Animals Immune to

[1] Zeit. f. Hyg. u. Infektionskrank., 1896, ii. p. 203.

the Typhoid-bacillus and the Colon-bacillus.—Löffler and Abel[1] have sought to determine whether the serum of animals immune against the typhoid-bacillus had any protective action against the bacillus coli, and vice versa. The results of their studies are given in the following summary: 1. By treating dogs with increasing doses of virulent cultures of typhoid-bacilli or bacillus coli communis bodies are generated in their blood which possess a specific protective power only against that species of bacterium to which they owe their origin. 2. Ordinary serum of untreated animals exerts a protective action not only against the simple fatal dose of typhoid- or colon-bacillus, but also against low multiples of this dose. The size of the dose bears some relation to the quantity of serum previously introduced. 3. The specific protective power of the bodies in question is also clearly revealed when mixtures of serum and bacteria are injected. 4. Typhoid-serum protects against a somewhat larger dose of colon-bacilli than normal serum, and, conversely, the colon-serum likewise against a somewhat larger dose of typhoid-bacilli than normal serum. In this somewhat heightened protective power the relationship of the two bacteria is to a certain extent made evident. 5. The specific sera do not protect against the substances contained in the bodies of bacilli in a greater degree than ordinary serum. 6. By the injection of normal serum into the peritoneal cavity of guinea-pigs, and 24 hours later of double the fatal dose of dead bacilli, guinea-pigs can be rendered immune to the 100-times fatal dose of typhoid-bacilli within 2 weeks. 7. In case of intraperitoneal inoculation of typhoid-bacilli, guinea-pigs bear within 48 hours the 100-times fatal dose if in the beginning a nonfatal dose is injected, and this is followed by ascending multiples of the fatal dose—*forced immunization.* 8. By the injection of 0.5 to 1 c.c. of a highly protective typhoid-serum animals that have been inoculated intraperitoneally with double the fatal dose can be saved 8 hours after an infection that in nontreated animals is fatal in 20 hours. 9. The author's experiments confirm the results of R. Pfeiffer with regard to cholera-serum.

Pfeiffer[2] sums up his recent observations on the specific **"antibodies" of cholera and typhoid fever** as follows: 1. The cholera-vibrios destroy when growing in bouillon-dilutions of cholera-serum the specific "antibodies" of cholera. Other vibrios, however, grow in this serum-bouillon mixture without directly attacking the antibodies. A partial destruction only occurs secondarily when, *e. g.*, by reason of the formation of metabolic products, the alkalinity or acidity of the medium reaches a harmful degree. 2. The specific antibodies affect in the test-tube the virulent cultures much less than the non-virulent. 3. In this easily determined difference we possess a measure of the virulence of a cholera- or typhoid-culture, since, *ceteris paribus*, the culture influenced by the greater dilutions of serum possesses a lesser virulence in the animal experiments. 3. When virulent cholera-cultures are used, it will be found, as previously pointed out by the author, that the inhibitory action of

[1] Centralbl. f. Bakt., Parasit. u. Infektionskrank., Jan. 23, 1896.

[2] Ibid., May 8, 1896.

the cholera-serum *in vitro* becomes unnoticeable when the dilution approaches the lower limit of activity in the animal body. In such cases the vibrios are dissolved in the animal body, yet in the test-tube the phenomenon of agglomeration, upon which so much stress is laid by Gruber, does not occur. 5. The normal serum of several animal species contains bodies of a nonspecific nature which in the animal can cause the dissolution of cholera- and typhoid-bacilli. These normal serums possess also *in vitro* a noticeable inhibitory, but not specific, action on cholera- and typhoid-bacilli. Here, too, the less virulent culture is more markedly influenced than the more virulent, though the differences are not as striking as in the case of the immune serum. 6. The strict specificity of the cholera and typhoid antibodies is not in the least put in question by these observations.

The Specific Substances in the Blood-serum of Animals Immunized against Cholera.—Pfeiffer and Proskauer[1] have made a careful chemic study of the serum of animals immunized against cholera, in order to determine whether the specific substances which dissolve the cholera-vibrios belong to the group of albumins normally present or not. By means of Pfeiffer's reaction it is possible to test the substances isolated, both qualitatively and quantitatively. Without going into the minutiæ of their laborious and patiently-performed experiments, it will suffice to state that the specific "antibodies" belong neither to the globulins nor to the serum-albumins; they are also not extractives, nucleoalbumins, nucleins, peptones, or albumoses, nor are the nitrogenous and nonnitrogenous substances of the blood the cause of the specific action of the serum. The question to what group of bodies the protective substances belong is thus not answered, though it is materially elucidated. The authors believe that their experiments, as well as analogy, permit them to consider the protective bodies as enzymes.

Active Immunization against Cholera in Man.—Kolle[2] has immunized 15 persons, himself included, against cholera by the injection of dead cultures of the vibrio, his method being similar to Haffkine's. The first dose was $\frac{1}{12}$ of a 24-hour agar-culture, injected into the back; in 5 days the same dose of a living, very virulent culture was injected, and in 5 days $\frac{1}{8}$ of such a culture. The serum of the persons was tested before immunization, and was found to protect a guinea-pig in doses of from 0.6 to 0.75 c.c. against 10 times the minimal lethal dose. After the injections 0.003 c.c. were sufficient. This is especially interesting when it is remembered that Pfeiffer found the serum of cholera-convalescents to have a lowest active limit at 0.01 c.c. (against 0.003 in artificially produced immunity). It was also found by Kolle that a single injection of a somewhat larger dose ($\frac{1}{5}$ culture) produced the same effect as the repeated smaller doses. The high bactericidal value of the serum after the injection of such a small dose would seem to disprove Buchner's theory, that the immunizing substances of the serum are derived from the bacterial substances. It is more reasonable to con-

[1] Centralbl. f. Bakt., Parasit. u. Infektionskrank., Feb. 21, 1896.
[2] Ibid., Feb. 5, 1896.

sider the cholera-antibodies as produced by an active reaction of the organism against the poisonous action of the bacteria. The protective action of the serum of persons vaccinated against cholera is strictly specific. The protection does not appear immediately after the inoculation, but only after a few days—not before the fifth day. As far as ascertained, the protective power of the vaccination lasts about a year. [On account of the rarity of epidemics vaccination against cholera will not be of such value in Europe and America as in India, but in case the disease should visit either continent measures could promptly be taken for the vaccination of exposed communities. Physicians, especially, could have themselves immunized. We would suggest that the bacteriologic laboratories of our seaports maintain cultures of virulent cholera-vibrios, so as to be able on short notice to furnish abundant vaccine.]

Haffkine's Cholera-immunization in India.—Kolle[1] reviews the work done by Haffkine in India, from which the conclusion is justified that the inoculation in man protects against cholera.

Serum-therapy in Tuberculosis.—Maffucci and Di Vestea[2] have tested the serum of "tuberculinized" sheep. (The adjective is applied to sheep treated with dead or living cultures of the tubercle-bacillus.) The guinea-pig, whether healthy or tuberculous, tolerates large doses of the serum; the rabbit, however, dies with symptoms of hemoglobinuria when injected with a dose of 0.4–0.5% to the body-weight. When a mixture of tubercle-virus and serum was injected into guinea-pigs, the animals died of tuberculosis at the end of a much longer period than the control animals. The serum did not possess a certain action, whether prophylactic or curative, on the experimental tuberculosis of guinea-pigs, but nevertheless produced (1) a longer duration of life; (2) a modification of the morbid process in its anatomico-pathologic character. In concluding the authors are of opinion that the serum possesses properties that are strongly analogous to those of tuberculin, and consider judgment in regard to sero-therapy in tuberculosis as premature.

Niemann,[3] in a series of experiments made for the purpose of obtaining a tubercle-antitoxin, found that an artificial immunity against infection with the tubercle-bacillus could be produced by subcutaneous injection of tuberculin or its active principles in dogs, goats, guinea-pigs, white rats, and hedgehogs. The immunity thus produced disappeared in from 4 to 7 weeks after the termination of the tuberculin-treatment. In the normal serum of the animals mentioned an antitoxic substance against tuberculin could not be found. The formation of antituberculin in the blood of the animals named (hedgehog not considered) can be achieved in one of two ways: (*a*) By the injection of mitigated tubercle-bacilli. (*b*) By treatment with tuberculin or its active principles. The simultaneous introduction of dead tubercle-bacilli seems to influence favorably the production of antitoxin. Goats from 1 to 2 years old are best adapted for the preparation of antitoxin. As the use of large quantities

[1] Centralbl. f. Bakt., Parasit., u. Infektionskrank., Feb. 21, 1896.
[2] Ibid. [3] Ibid.

of tuberculin produces hemoglobinuria in consequence of glycerol-poisoning, the author now employs the toxin obtained by precipitation with alcohol. The antitoxic value of the serum in immunized animals is illustrated by two tables, from which we glean that the serum greatly prolongs the life of tuberculous guinea-pigs receiving a mixture of tuberculin and serum.

Babes and Proca[1] have been led to the following conclusions by their experiments with tuberculosis-serum: 1. The dead bacteria remain active, even after the careful extraction of the tuberculin, and produce lesions analogous to those caused by the living bacilli. 2. The effect of the serum differs in several points from that of tuberculin: (*a*) The antituberculosis-serum, even if injected in large quantities, produces no deleterious effects; (*b*) even in large quantities it causes only a slight rise in temperature; (*c*) if the serum is mixed with tuberculin, it paralyzes the action of the latter, but only when this is present in small quantities. 3. The serum prevents the local lesions produced by dead bacilli, and has a healing influence upon them when they exist. 4. When animals are injected simultaneously with tubercle-bacilli and serum, tuberculosis does not develop. 5. Tuberculosis may be cured if serum-injections are begun within a few days after infection. 6. The cure of the infected animals can be produced by relatively large doses of serum; smaller doses are ineffectual, and seem to increase the disease. In animals cured by this method no tuberculous lesions were found at autopsy performed several months later. 7. Media favorable to the growth of tubercle-bacilli become unfavorable when exposed for a time to the action of the serum. 8. Tubercle-bacilli mixed with antituberculosis-serum *in vitro* lose their virulence toward rabbits.

Johannessen,[2] in order to determine whether the **incidental effects of the diphtheria antitoxic serum** were due to the horse-serum *per se*, injected 22 persons (21 children, 1 adult) with serum from horses that had not been immunized against diphtheria. He is led to conclude from the experiments that the untoward effects of the serum-treatment are chiefly the result of the introduction of foreign serum, and advises that the antitoxin should be as concentrated as possible in order to lessen the quantity of serum injected, and also to be cautious in the use of the serum when diphtheria does not exist.

Loos[3] has investigated the **behavior of the blood-serum** of healthy and diphtheric children **to diphtheria-toxin.** 1. He endeavored to determine whether it was possible to demonstrate in the blood the presence of antitoxin that had been injected. A child of 3, whose blood had been found to possess but slight antitoxic properties, received 2000 antitoxin-units. The serum obtained by a second venesection 14 hours afterward presented indubitable antitoxic qualities. Attempts to find the antitoxin in the urine did not give positive results. 2. It was not possible to demonstrate a change in the blood-serum of children that had received a prophylactic injection (150 A. U.). 3. The third series of experiments was made for the purpose of determining

[1] La Méd. moderne, 1896, p. 37. [2] Deutsch. med. Woch., 1895, No. 51.
[3] Wien. klin. Woch., May 28, 1896.

whether after recovery from diphtheria the blood contained antitoxic substances. A 3-year-old child had been in the hospital for some time; its blood had been examined and was found almost devoid of antitoxic properties. The girl developed diphtheria. Fifteen days after convalescence, and also in 60 days, the author was able to demonstrate the existence of well-marked antitoxic properties in the blood-serum. 4. The author found antitoxic substances in the blood of 2 convalescent cases in whose blood they were not present during the course of the disease. 5. In the mouths of 2 healthy children highly virulent diphtheria-bacilli had been found at Prof. Escherich's clinic. The assumption that these children owed their immunity to antitoxic properties of their blood-serum was proved correct by experiment. 6. In one case of diphtheria the author succeeded in demonstrating the presence of toxin in the blood during life. 7. The question as to whether the antitoxic properties of normal blood-serum—*i. e.* of the serum of individuals that had not suffered from diphtheria—were permanent or not was settled in the affirmative. Any change, therefore, produced by diphtheria or by injections of antitoxins must be due to that cause.

Pawlowsky and Maksutow[1] describe **a new method of immunizing horses** for the purpose of obtaining a strong diphtheria-antitoxin. They first inject a considerable quantity of antitoxin under the skin, and then in 2 or 3 days the toxin, beginning with a large dose.

Treatment of Diphtheria with Artificially-prepared Antitoxin.—Smirnow[2] says if a diptheria-bouillon or serum-culture is subjected to electrolysis, the fluid at the positive pole becomes strongly alkaline, that at the negative pole strongly acid. If the two fluids are separated and neutralized with HCl and NaOH respectively, they not only lose their toxicity, but even acquire an immunizing power. Veal-bouillon was found to yield the strongest, horse-flesh bouillon the weakest toxin. The reaction of the medium is also an important factor. While the action of the artificial antitoxin is similar to that of the antitoxin obtained from immunized animals, it is noteworthy that, differing from the latter, an excess is distinctly injurious and must be carefully avoided. Experiments on guinea-pigs have shown that the antitoxin itself is not innocuous. It is, therefore, evident that the antitoxin obtained by electrolysis is nothing more than an attenuated toxin, the toxicity of which is diminished proportionately to the duration of the electrolysis.

Vissman[3] produced cloudy swelling in the kidneys of rabbits by the injection of diphtheria-antitoxin, and thinks that the use of **antitoxin** has increased the **death-rate** from diphtheria. [Despite these observations, overwhelming statistics by observers in all civilized countries testify to the value of antitoxin in diphtheria.]

Treatment of Typhoid Fever with Antitoxic Serum.—Börger[4]

[1] Zeit. f. Hyg. u. Infektionskrank., 1896, xxi. 3.
[2] Berl. klin. Woch., Nos. 30 and 31, July 29 and August 5, 1895.
[3] N. Y. Polyclinic, Nov. 15, 1895.
[4] Ref. in Centralbl. f. Bakt., Parasit. u. Infektionskrank., May 8, 1896.

employed antitoxic sheep-serum prepared by Beumer and Peiper, but could not observe any noteworthy influence on the course of the disease. The fact that cases of typhoid fever rarely come under treatment before the tenth day may have something to do with the negative results.

Chantemesse[1] has **immunized horses to the typhoid-fever bacillus.** The serum possesses such protective power that $\frac{1}{3}$ drop injected into a rabbit protects against the fatal dose introduced 24 hours later. The serum was used in 3 typhoid patients; all were perfectly well in 7 days from the first injection.

Antistreptococcic Serum.—Marmorek,[2] in order to procure a strong serum, first prepares a very virulent culture of streptococci by passage of the germs through a series of animals, and maintains the attained virulence by the use of a proper culture-medium, the best being a mixture of human blood-serum (2 parts) and 1% peptone-bouillon (1 part). Ascitic fluid may be used in the proportion of 1 part to 2 parts meat-bouillon. Ass's serum or mule's serum (2 parts to 1 of bouillon) and horse's serum (in the same proportion) may be employed, but are not so good. By growing the streptococci alternately in this medium and in the bodies of rabbits he has obtained cultures of almost incredible virulence. Horses and asses were immunized by the subcutaneous inoculation of cultures (not of toxins, since they were not obtained of great strength), and after a period of 6 months the serum of these animals was found to possess immunizing and, to a less extent, curative powers. Marmorek considers all pathogenic streptococci as belonging to the same species, the lesions depending on the degree of virulence and the point of entrance of the germs. An attempt was made to immunize horses that had already been immunized against diphtheria, and thus to obtain a serum that could be used in cases in which both the diphtheria-bacillus and the streptococcus are present in a pseudomembrane. Curiously enough, the horses showed almost no reaction after injections of virulent cultures of streptococci.

Therapeutic application of the serum has been made in erysipelas and other streptococcus-infections, but the cases treated are yet too few in number for trustworthy conclusions.

Antistaphylococcic Serum.—Kose[3] has been able partially to immunize a goat against staphylococcus. The serum of such an animal possesses antitoxic (but no bactericidal) properties.

Antianthrax Serum.—Marchoux[4] has obtained an antitoxic serum by the graduated inoculation of bouillon-cultures of anthrax-bacilli.

Sclavo,[5] by the injection of increasing doses of virulent anthrax-bacilli, the treatment having been begun with Pasteur's vaccine, was able to render sheep immune, and found that their blood possessed an antitoxic value. The author

[5] Centralbl. f. Bakt. u. Parasit., Dec. 23, 1895, No. 24.

hopes that it may be possible to treat anthrax in man and in animals by means of serum-therapy.

Erysipelas-toxins in Malignant Disease.—Czerny[1] does not think that cases of malignant disease are much benefited by injections of the combined toxins of erysipelas and micrococcus prodigiosus, yet believes that in inoperable cases the treatment deserves trial. In 2 cases—one a sarcoma of the parotid, the other a carcinoma of the upper jaw—he observed softening of the tumors and material improvement.

Serum-therapy in Carcinoma.—Salvati and Gaetano[2] injected 5 cases of carcinoma with the serum of a horse previously treated with intratracheal injections of the juice from a sarcoma. The lancinating pains disappeared for a time, but later returned. Hemorrhage from the ulcerated surfaces was a frequent sequel of the injection. No arrest of growth of the tumor took place.

Boureau[3] treated 7 cases with the serum of an ass injected according to the method of Richet and Héricourt. The animal received 55 c.cm. of a liquid obtained from an epithelioma of the breast and a carcinoma. The injections produced a prompt rise of temperature of 3° C., which was followed by a fall that was rapid after the first, but slower after the later injections; 2 bleedings, practised 6 days and 14 days respectively after the injections, yielded the serum which was injected into the patients. The author's conclusions are—1. That the serum of animals that have received inoculations from cancerous tumors produces a rapid amelioration (6 cases in 7) as regards pain, congestion, and suppuration. 2. That in the majority of cases this amelioration persists, but does not impede the course of the cancerous disease. 3. That although the method is not curative of cancer in the strict sense of the word, it nevertheless constitutes a form of treatment superior to any employed at present.

Héricourt and Richet, at the same meeting of the Société de Biologie, stated that the immediate effect of their method is without exception the production of a striking improvement.

Antitoxins and Toxins; their Preparation in the Dry State.—Brieger and Boer[4] have made a series of experiments to find a method by means of which the antitoxin could be obtained pure from blood-serum. The best precipitant was sodium chlorid combined with potassium chlorid, or at times with potassium iodid, acting at temperatures of from 30 to 37° C. The antitoxin could be completely isolated in this way, the strength of the serum not playing any part. Ten c.c. of diphtheria-serum yield 0.4 gr. of dried precipitate, which was soluble in about an equal quantity of water, but contained yet some albumin and salts. The salts were removed by dialysis. It was more difficult to remove the albumin. To a certain extent this could be accomplished by treating the antitoxin with magnesium sulphate in the incubator. The residue, which contained all the antitoxin, weighed 0.2 gr. By the same method of concentration the authors were able to extract all the anti-

[1] Münch. med. Woch., Sept. 3, 1895. [2] Rif. med., Aug. 12 and 20, 1895.
[3] Comp. rend. de Soc. de Biol., 10th Series, t. ii. No. 27, Aug. 2, 1895.
[4] Zeit. f. Hyg. u. Infektionskrank., 1896, ii. p. 259.

toxin from the milk of goats immunized against tetanus. A liter of milk having an immunizing value of 30,000 yielded 1 gr. of a very soluble powder representing the original antitoxin-strength. An effort was made to isolate the toxins; mercuric chlorid, zinc sulphate, or, best of all, zinc chlorid, precipitates quantitatively the tetanus-toxin and diphtheria-toxin. The zinc-toxin compound does not contain a trace of albumin; hence diphtheria-toxins and tetanus-toxins cannot be considered albumins in the ordinary acceptation of the term. A liter of the toxic bouillon yields about 3.0 gr. of the dried zinc compound, of which 0.3 gr. are organic substances and represent the total amount of toxin. [It was natural to expect epoch-making work of this kind from the man who has done so much to advance our knowledge of bacterial poisons. From the practical point of view these investigations are of the greatest value, and lead us to hope that we shall soon be able to obtain the antitoxins in a solid, readily soluble, and nonperishable state. It is not out of the reach of possibility that we may yet be able to carry the curative substances in the hypodermic case.]

D'Arsonval and Charrin[1] have succeeded in **attenuating toxins** by passing constant or interrupted currents through them. By varying the strength of the current the toxins could be so altered as to serve as vaccines.

Antivenene.—Fraser[2] has continued his researches on antivenene, and comes to the conclusion that the latter is a chemic antidote to venom. The reasons for this conclusion are, in the first place, that a very much smaller quantity of the antivenene is required to neutralize the venom when the two are mixed in a test-tube than when they are separately but simultaneously injected. It was also found that when mixed in a certain proportion with the venom *in vitro* antivenene was able to prevent death from almost any dose of venom, however large it might be. Large doses of venom introduced into the stomach of animals failed to cause death, but seemed to produce a certain degree of immunity. This, together with the fact that the greater the quantity of venom introduced into the body the greater the quantity of antivenene produced, leads Fraser to conjecture that antivenene may be a constituent part of the venom itself. He does not believe that phagocytosis plays any part in the immunity, which he considers to be due to the chemical neutralization of the venom by the antivenene. At present the immunizing and curative value of the antivenene-serum is such that very large doses are required to produce results in the case of snake-bite in man, but the author hopes that it may become possible to separate the antivenomous principles from the inert constituents of the blood-serum with which they are mixed.

Technic—Pathologic and Bacteriologic.—Kanthack and Stephens[3] recommend the use of **serous fluid** (ascitic, pleuritic, hydrocele) for the preparation of a culture-medium for the diphtheria-bacillus.

McCann[4] suggests the use of **fluid from ovarian cysts as a culture-medium** for the gonococcus and other microorganisms.

[1] La Sem. méd., Feb. 5, 1896.
[2] Brit. Med. Jour., Apr. 18, 1896.
[3] Lancet, Mar. 28, 1896.
[4] Ibid., May 30, 1896.

Piorkowski[1] uses **urine culture-media** for differentiation of the bacillus coli and the typhoid-bacillus. The latter grows more slowly, and produces, on plates or in stab-cultures, a delicate, transparent growth, as if it had been breathed in (*eingehaucht*).

The Preservation of Virulent Cultures of the Streptococcus.—Petruschky[2] has found that by growing the streptococcus in gelatin for 2 days, and then placing the cultures in the ice-chest, the vitality and virulence of the organism are preserved for months.

Tochtermann[3] recommends the following **culture-medium** for the rapid cultivation of the diphtheria-bacillus. A 2% watery agar-solution, containing 1% peptone, 0.5% salt, and from 0.3 to 0.5% glucose, is boiled for from $\frac{1}{4}$ to $\frac{1}{2}$ hour with an equal part, or in the proportion of 2 to 3, of sheep's blood-serum. The filtrate is placed in test-tubes and sterilized in the usual way (for from 1–1$\frac{1}{2}$ hours on 3 successive days). The blood need not be received under antiseptic precautions; the serum is decanted after 24 hours. The presence of a few red corpuscles is not significant, as after boiling the filtrate becomes clear. If the medium, after remelting, is poured into Petri dishes and allowed to congeal, and is then inoculated with the diphtheric material, diphtheria-colonies may be seen with the microscope in 12 hours; in several cases they were found as early as 8 hours. [This medium would be very valuable if it would enable such an early diagnosis.]

Staining of Diphtheria-bacilli.—Crouch[4] states that if a cover-glass, prepared in the usual way from a serum-culture not older than 24 hours, is treated for a few seconds only with a 1% solution of methyl-green and then immediately rinsed and examined in water, very often the following will be observed: The majority of the bacilli are stained faintly green, and contain at both ends a well-defined round body much more deeply stained and of a distinctly reddish color. This is particularly striking in cultures containing mainly the shorter and uncharacteristic forms. The effect may be still further increased by the addition of other colors to the methyl-green for the purpose of contrast and increased penetration. Thus a combination of dahlia with the methyl-green is very effective. The following mixture has been found most suitable by the author: 5 parts of a fresh 1% solution of methyl-green, 1 part of a fresh 1% solution of dahlia, and 4 parts of water. The mixture improves with age. The peculiar staining reaction is claimed to be characteristic. The nature of these bodies is not known; they are different from the disks and striations of the ordinary preparations. The author considers them, with Ernst, nuclear in character. They stain with hematoxylin. After staining with dahlia-methyl-green, the bacilli may be stained faintly with Bismarck-brown; this gives very clear pictures.

Pittfield[5] recommends a **method for staining flagella** consisting in

[1] Centralbl. f. Bakt., Parasit. u. Infektionskrank., May 23, 1896.
[2] Ibid., xviii. No. 16, Oct. 31, 1895.
[3] Centralbl. f. innere Med., 1895, No. 40.
[4] N. Y. Med. Jour., Oct. 5, 1895.
[5] Med. News, Sept., 7, 1895.

the use of but a single solution, which is at once mordant and stain. The solution should be made in 2 parts, which are filtered and mixed:

A. Saturated aqueous solution of alum . . . . . 10 c.cm.,
Saturated alcoholic solution of gentian-violet . . . . . , 1 c.cm.
B. Tannic acid . . . . . 1 g.,
Distilled water . . . . . 10 c.c.

The solutions should be made with cold water, and immediately after mixing the stain is ready for use. The cover-slip is to be carefully cleaned, the grease burned off in a flame, and after the slip has cooled the bacteria are spread upon it, well diluted in water, care being taken to exclude culture-medium. After the preparation has been thoroughly dried in the air it should be held over the flame with the fingers, as Löffler has directed. Afterward the stain is gradually poured on the slip and heated gently, bringing the fluid almost to a boil; the slip covered with the hot stain should then be laid aside for 1 minute, then washed in water, and mounted. The flagella are clearly stained. If the mixture is filtered, the preparation will be cleaner, but the flagella will not be stained as distinctly.

Hamilton[1] has devised a new **apparatus for the cultivation of anaerobic bacteria,** for a description of which we refer to the original.

The Cultivation of Amebæ.—Beyerinck[2] has succeeded in growing 2 species of ameba on solid media. The first, *Amœba nitrophila*, occurs associated with the nitrite-ferment; and the second, *Amœba zymophila*, which is perhaps identical with the amœba coli of Lösch, is found in some forms of alcoholic fermentation. (Concerning the preparation of the media see the original.) Schardinger[3] uses hay-infusion agar as a culture-medium for amebæ, and succeeded in growing a species, obtained from the stool of a patient suspected to be suffering from typhoid fever, which seemed to be identical with ameba coli. The medium is simply prepared: 30–40 g. of hay or straw are boiled with 1 liter of water; to the filtrate 1–1.5 % agar is added; the mixture is boiled until the agar is dissolved, and Na_2CO_3 is added to an alkaline reaction. The material is placed in test-tubes without filtration. Celli[4] makes public a method for the cultivation of amebæ, which he and Fiocca described at a meeting of an Italian society in Nov., 1895. The best medium is made from fuscus crispus, which is prepared with 5 % water, with or without bouillon, and is strongly alkalinized. It is almost impossible to obtain cultures of amebæ free from bacteria. The authors succeeded in cultivating a large number of amebæ, among them amœba coli. Regarding the etiologic relation of the latter to dysentery, they consider that it is not proved.

Jores,[5] noting that in the **conservation of tissue with formalin** the color of the blood was usually not perfectly preserved, found that the use of

[1] Brit. Med. Jour., Jan. 4, 1896.
[2] Centralbl. f. Bakt., Parasit. u. Infektionskrank., Feb. 28, 1896.
[3] Ibid., Apr. 25, 1896. [4] Ibid.
[5] Centralbl. f. Allg. Path. u. Pathol. Anat., 1896, No. 4.

salt-solution instead of water for diluting the formalin produced better results. At the same time, the tissues so treated are better adapted for microscopic study. He uses the following: Salt, 1 part; magnesium sulphate, 2 parts; sodium sulphate, 2 parts; water, 100 parts. Organs placed in the solution change color and assume a dirty hue, but when transferred to 95% alcohol the color gradually returns. The pieces may be kept in the alcohol until permeated, and afterward may be placed in an indifferent preserving fluid, a mixture of glycerol and water, in which the color assumes its natural tint.

Cullen's[1] method of **staining frozen sections** is as follows: (*a*) Place the frozen section in 5% aqueous solution of formalin for 3 to 5 minutes. (*b*) Leave in 50% alcohol 3 minutes. (*c*) In absolute alcohol 1 minute. (*d*) Wash out in water. (*e*) Stain in hematoxylin for 2 minutes. (*f*) Decolorize in acid alcohol. (*g*) Rinse in water. (*h*) Stain with eosin. (*i*) Transfer to 95% alcohol. (*j*) Pass through absolute alcohol, then through either creosote or oil of cloves, and mount in Canada balsam. By fixing the specimen in formalin before it is frozen the blood may be preserved. This process requires at least 2 hours. A small piece of the tissue is placed in a 10% solution of formalin and allowed to remain for 2 or 3 hours. It is then put on the freezing microtome and cut into thin sections. The great advantage of this method is the prevention of the contraction of the tissues, such as takes place when frozen sections are passed through alcohol.

Plenge[2] describes a **method of preparing frozen sections** hardened in formalin, which resembles that of Cullen. He uses a 4% solution of formaldehyd.

A Method of Reproducing the Naked-eye Appearance of a Microscopic Section.—Hamburger[3] describes the following process: The section is obtained and mounted in balsam in the customary manner. A piece of sensitized paper (3 of diagram below) is taken, and with its sensitive side is laid on the cover-glass (4), the section being on a glass slide (5); a piece of

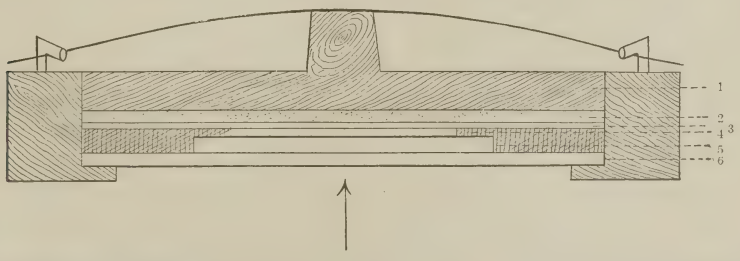

FIG. 126.—Method of reproducing the naked-eye appearance of a microscopic section (Rev. de Méd., Dec. 10, 1895).

rubber (2) covers the paper, and upon the rubber a plate of wood (1) is laid. The whole rests on the glass-slide (6). After having pressed the different layers together, the preparation is exposed to diffuse light. The time required

[1] Johns Hopkins Hosp. Bull., Apr., 1895. [2] Münch. med. Woch., Jan. 28, 1896.
[3] Rev. de Méd., Dec. 10, 1895.

is a matter of practice. The subsequent development is like that in ordinary photography. The balsam should always be hard before the preparation is photographed. All manipulations except, of course, the exposure are conducted in a darkened room (see Fig. 126).

MISCELLANEOUS.

The Diagnosis of New Growths by Microscopic Examination of Transudates.—Rieder[1] calls attention to the value of microscopic examination of peritoneal and pleural fluids in obscure cases in which malignant disease of the respective serous membrane is suspected. In a case in the care of Von Ziemssen the author found, in the fluid obtained by paracentesis abdominis et thoracis, cells occurring in masses and presenting atypical and irregular mitoses, and the diagnosis of malignant disease, probably carcinoma, was made. At the autopsy sarcoma of the peritoneum and pleura, omentum, and diaphragm was found, probably originating in the ovaries. In reference to the nature of cells found in transudates the diagnosis must be made between endothelial and cancer-cells. The latter are said by Quincke to give the glycogen-reaction [the assumption of a mahogany-brown color on the addition of a solution of iodin in glycerol]; they are of large size, occur in masses, and present atypical mitoses. An interesting feature in the author's case is the development of a new growth at the point of puncture in the abdominal wall. [The author terms the growth found by him on section of a peritoneal nodule a combination of sarcoma and carcinoma—sarcoma carcinomatodes. This can hardly be the proper conception of the tumor; it was either an alveolar sarcoma or that peculiar form of sarcoma termed endothelioma.]

On the Passage of Particulate Elements through the Diaphragm.—Sulzer[2] injected into dogs wheat-grits rubbed up in sterile salt-solution, in order to determine to what extent particulate elements in the abdominal cavity were absorbed by the diaphragm by entering the stomata directly, rather than by being carried into the lymphatics by means of leukocytes. The particles injected were, on a average, 20μ in diameter. The peritoneal surface of the diaphragm was found to be studded with little masses of the granules at points corresponding with the mouths of stomata which communicated with lymphatic spaces. The latter do not communicate with each other, but by fine branches with the rich lymphatic network on the thoracic side of the diaphragm. Both the spaces and the thoracic lymphatics were rich in granules. In the muscular portion of the diaphragm granules unenclosed in leukocytes were found. Particles four or five times the size of a red corpuscle can directly enter the stomata, and this is probably the primary mode, since absorption is well advanced in from 5 to 10 minutes. Later, particles enclosed in leukocytes are more numerous.

[2] Virch. Arch., Jan., 1896, Bd. cxliii. p. 99.

The Fibrinoid Degeneration of Connective Tissue in Inflammation.—Neumann[1] believes that the fibrin-patches on the surface of serous membranes are not caused by an exudate, but by a fibrinoid degeneration of the superficial connective tissue, by which a modified albuminoid substance is formed, just as in amyloid degeneration. In favor of this is the localization of the patches, as over a tuberculous ulcer of the intestine or over a patch of inflamed lung, which, he maintains, would not occur if the material were exuded in a fluid state, as the rubbing of the pleuræ or the peristaltic motion of the intestine would tend to dislodge or to spread it. He was able to find islands of epithelium covering the patches, and at the edges of the patches the epithelium goes over and not under the fibrin. Fibrinous masses were found below the level of the surrounding epithelium, in the midst of connective tissue, and the fibers of the connective tissue were directly continued into the mass. Similar findings in the walls of tuberculous cavities, in the vegetations of verrucose endocarditis, and in inflammation of synovial membranes lead the author to ascribe these fibrinous formations to the same fibrinoid degeneration of connective tissue. [It is difficult to understand how the process described by Neumann could account for the thick fibrinous masses seen, *e. g.*, in fibrinous pericarditis, or for the stout bands that pass between the parietal and visceral layers of the pericardium in that disease. We doubt not that there is a coagulation-necrosis of the superficial tissues leading to the formation of a fibrinous substance, but an additional source is needed to account for the immense quantities of fibrin often found in serous membranes, and it is plausible to seek this in an exudation of a coagulable material.]

The Lesions produced by Lightning-stroke and other Electric Discharges.—Dürck,[2] from a study of a case in which lightning had caused instantaneous death, and from a review of the cases reported in literature, concludes that the electric current of sufficient tension, whether it be in the form of lightning or of a discharge from an electric machine, is capable of injuring or destroying the body by transient or permanent arrest of the respiratory or cardiac centers. The anatomic changes are: 1. Retarded or absent coagulability of the blood; 2. Usually circumscribed or extensive laceration of vessels in the track of the current; 3. At times disorganization of specially-affected parts; 4. The presence of superficial or deep wounds, resembling burns, at the points of entrance and exit of the current. Regarding the nature of the so-called lightning-figures (*Blitzfiguren*) further observations are necessary. Decomposition appears to be no more rapid than in other conditions.

The Importance of Granulation-tissue in Infection with Pathogenic Microorganisms.—Afanasieff[3] established wounds in various animals, and after 3 or 4 days inoculated pathogenic bacteria (anthrax, vibrio Metschnikowi) at the site of the wounds, and found that the animals survived. Granulation-tissue, he concludes, offers a sure protection against the entrance of virulent bacteria into the organism. The destruction of the bacteria planted

[1] Virch. Arch., May, 1896, Bd. cxliv. p. 201. [2] Münch. med. Woch., July 30, 1895.
[3] Centralbl. f. Allg. Path. u. Pathol. Anat., June 15, 1896.

upon the granulation-tissue begins with the action of the tissue-juices upon them; phagocytosis is observed later. Animals can be immunized by infection of a granulating wound with virulent cultures. The cultures obtained from granulation-tissue are attenuated. These researches indicate a new, simple, and certain method for the immunization of animals against various infectious diseases. At the same time it offers a prompt method of obtaining attenuated cultures that can serve as vaccines. [These studies are interesting, but whether the method is applicable to man is questionable. We shall look forward to the author's promised thesis with great interest.]

Surgical Infectious Diseases.—Kocher and Tavel[1] discuss this subject—Kocher from the clinical, Tavel from the bacteriologic standpoint. Of interest to us is the terminology proposed by the authors. Tavel distinguishes sharply between infection and intoxication. There are two chief classes of infections—that from the outside, *exogenous*, and that from the blood, *hematogenous*, infection. If bacteria develop at a distance from the point of introduction, the mode is termed *resorption-infection*. The latter may be exogenous or hematogenous. The word septicemia the author would drop entirely, and would differentiate between blood-infection—*bacteremia*, and blood-intoxication—*toxinemia*. The term "mixed infection" should also be discarded, and *polymicrobic* infection used instead. The latter is *homologous* when all foci are produced by the same association of bacteria; a *heterologous* infection may be a monoinfection when the same species of bacteria is not found in all foci, but in every focus only one exists. Inflammation and suppuration are considered as healing processes in the sense of Metschnikoff, in which phagocytosis is the most active factor. A chapter is devoted to *staphylomycosis*. The authors would drop the term pyemia and designate the conditions produced by invasion of staphylococci as *staphylomycosis circumscripta acuta* and *chronica*, *staphylomycosis multiplex* and *metastatica*, and *staphylohemia*.

Toxicity of the Aqueous Part of the Breath.—Livierato[2] investigated the toxicity of the aqueous vapor expired by healthy and by sick persons. Expired air was received and the aqueous vapor condensed in suitable apparatus; the fluid obtained was then injected into rabbits with the following results: 1. Aqueous vapor from persons suffering from diseases of the respiratory tract, with fever, injected into rabbits, produced a fever which lasted from 3 to 6 days, general torpor, and diminution of reflexes. 2. These effects were less accentuated in the case of patients who had no fever. 3. The aqueous vapor of febrile patients having no respiratory trouble caused no fever or only very slight fever in rabbits. 4. The vapor of healthy individuals had no appreciable effect. 5. Identical results were obtained when the liquid was sterilized.

The Pathology of Talalgia.—Brousses and Berthier[3] contribute an interesting study of a case of this disease. The pathologic condition—the symp-

[3] Rev. de Chir., Aug., 1895.

toms having been an almost unbearable pain on resting the foot upon the heel—consisted in an interstitial neuritis of an anomalous nerve curving through the bursa normal to the heel.

Flagellate Protozoa in the Intestinal Canal of Man.—Schürmayer[1] found flagellate protozoa, evidently a form of trichomonas, in the intestinal canal of a child 1 year old, suffering with symptoms resembling summer-complaint. The organisms were spindle- and club-shaped, possessed two flagella at the enlarged end, and contained bodies (contractile vacuoles) the exact nature of which was not entirely clear. It was found impossible to secure cultures of the protozoa free from bacteria. Schmidt[2] found **protozoa** (trichomonas pulmonalis) **in the sputum** of 3 patients—2 with aspiration-pneumonia, 1 with gangrene of the lung. In all cases the parasites were found in the Dittrich's plugs.

Trichomonas as a Parasite of Man.—Dock[3] adds the third case of trichomonas in urine to those already known (Marchand, Miura). The patient, a man of 27 years, had difficulty in urination and periodic hematuria. The author describes exhaustively the morphologic and biologic properties of the trichomonas, to which he attributes pathogenic power, which in the case reported manifested itself in the production of hematuria and pyuria.

PEDIATRICS.

By LOUIS STARR, M. D., and THOMPSON S. WESTCOTT, M. D.,

of Philadelphia.

The Year's Work.—While the work in our department during the year has been more diversified than in the preceding twelvemonth, as a result of the gradual subsidence of the excitement over the diphtheria antitoxin, there is little of novelty to record, though good earnest work along all lines is to be noted. Diphtheria is still actively under discussion. Concerning the new treatment the verdict of the profession, as gathered from the literature, is becoming gradually more and more emphatic that antitoxin surpasses in value all other remedies, and as the importance of early injection is being realized the results are correspondingly better. Touching the subject of scarlatina some suggestive claims have been advanced. Experiments with Marmorek's antistreptococcic serum have in general been disappointing, and this agent seems to have little or no effect in preventing the usual streptococcic complications of the disease. Whether the streptococcus found in scarlatinal complications (for its presence in the uncomplicated disease is now questioned) possesses properties differing from those of the erysipelatous germ, as is likewise claimed, remains for future demonstration.

The very exceptional occurrence of typhoid fever in children under the age of two years seems now fairly proved. Varicella is gradually assuming a position among infectious diseases entitling it to greater respect than has previously been accorded it, what with the possibilities of complicating nephritis, as shown last year, and of suffocative laryngitis, as demonstrated by Marfan and Hallé's interesting observations referred to in the present volume. In the treatment of pertussis phenocoll hydrochlorate seems to be the latest claimant for specific honors, and vaccination is again brought forward. Kossel's plan of making cultures from the stools of children with tuberculous pulmonary lesions with the view of detecting the bacillus in swallowed sputa is worthy of more extended trial. The importance of what may be termed the maternal factor in the etiology of rickets is emphasized by Garrod and Fletcher. Quincke's operation of lumbar puncture seems to be destined to take rank with exploratory celiotomy as a method of direct diagnosis. Many instances of its positive results have been recorded during the year, and it is generally agreed that the operation is harmless if properly done, though alarming symptoms are recorded in 1 case under the care of American observers.

PHYSIOLOGY.

The Increase in Weight of Premature Infants.—Potel devotes his thesis [1] to a consideration of the increase in the weight of premature infants, basing it upon a study of 173 infants born at periods from $6\frac{1}{2}$ to 8 months of intrauterine life, who survived the dangerous period and were discharged from the maternity after a sojourn of an average of 82 days for the $6\frac{1}{2}$-months' children and of 28 days for those of 8 months. At $6\frac{1}{2}$ months there was a survival of 19.6%. The average increase in weight per day for one of these children was 9.4 gm. At 7 months the survival was 41.9%; the mean daily increase of weight was 11.5 gm. At $7\frac{1}{2}$ months the survival was 69% and the increase of weight 13.8 gm. At 8 months 64.5% survived and the daily increase averaged 22.8 gm. The average weights at birth were as follows: At $6\frac{1}{2}$ months, 1408 gm.; at 7 months, 1700 gm.; at $7\frac{1}{2}$ months, 1900 gm.; and at 8 months, 2150 gm. The loss of weight of the first 3 days in the premature is not more marked than in infants at term, but its consequences are more grave, since the recovery of the initial weight takes longer; it is also during this period of loss or stationary weight that the mortality is highest, those infants exempt from hereditary taint being the most resistant.

Hemihypertrophy.—A case of congenital unilateral asymmetry, very similar to that reported by Adams (see *Year-Book* for 1896), has come under the notice of Kopal.[2] In this case there was increase of size of the face, limbs, neck, thorax, abdomen, pelvis, and scrotum upon the right side of the body, together with bilateral enlargement of the tongue—a feature not observed in Adams's case. A portion of the enlarged tongue was removed, showing no abnormality except an increased thickness of the muscular fibers.

Chemistry of Bile.—Baginsky and Sommerfeld[3] present a new analysis of the bile in childhood, based upon specimens taken from the dead bodies of 115 children whose livers were in a healthy condition. The ages varied from 3 months and younger (55 cases) to between 2 and $2\frac{3}{4}$ years (18 cases). Comparing their results with Jacubowitsch's [4] well-known analysis of the bile of new-born babies and sucklings, we find that as regards water, mucin, salts, and cholesterin the two analyses are practically the same. The new analysis, however, shows the presence of glykocholic acid, which did not appear in Jacubowitsch's results, and also of leucin, which, like lecithin, was found in unexpectedly large proportion.

INFANT-FEEDING.

A New Sanitary Nursing Device.—Decker[5] describes an improvement upon the usual form of nursing-bottle and nipple. The bottle is a graduated glass cylinder with an uncontracted outlet. The nipple is formed like a woman's breast, consisting of a broad elastic diaphragm fitting over a flange on the top of the bottle, with a short nipple projecting from its center.

[1] Paris, 1895.
[2] Prager med. Woch., No. 33, 1895.
[3] Archiv f. Kinderheilk., Bd. xix. S. 321.
[4] Jahrb. f. Kinderheilk., Bd. xxiv. S. 373.
[5] N. Y. Med. Times, Nov., 1895.

The fluid is thus discharged into the front of the mouth instead of directly down the throat, and its flow is much slower than that from the common nursing-bottle. This breast-nipple is reversible and easily cleansed.

Bottle-cleansing.—For cleansing nursing-bottles Seibert[1] recommends Heubner's use of green soap and warm water, but has been able to increase the germicidal action of this soap by letting the bottles stand for hours filled to the very top with the soap-water, and later, instead of a bristle bottle-brush, using plugs of absorbent cotton wound around the end of a strong wire to wipe away all remaining particles of milk, a fresh plug to be used for each bottle. Whenever possible, two sets of bottles are used.

Analysis of Condensed Milks.—A significant commentary on the use of condensed milk as a regular diet for infants is found in the report of the English Commission recently appointed to examine into the milk-supply of London: 17 brands of condensed milk were examined, and of this number 14 were found to be prepared from skimmed milk and showed an average of 0.72% of fat; 3 brands prepared partly from skimmed milk showed an average of 3.14% of fat. When it is considered that genuine condensed milk prepared from whole milk contains from 10 to 12% of fat, the food-value of most of the preparations on the market can readily be judged.

Analyses of Cow's Milk.—Heubner[2] brings additional testimony to the support of his analyses,[3] showing a low percentage of albuminoids in human milk, against the criticisms of Pfeiffer,[4] Biedert,[5] and Camerer,[6] who contend for a higher proportion. He criticises the precipitation-method of Ritthausen, employed by Pfeiffer, as being more liable to error than the method of Kjeldahl, which estimates the nitrogen and from this calculates the albuminoids. He refers to the analysis of Johannessen (see *Year-Book* for 1896, p. 526), which gives an albuminoid percentage of 1.104, and shows that if Wroblewski's factor 6.7 be used instead of the usual 6.25, or 6.37 which Johannessen used, a result of 1.16 is obtained, only .04 less than Forster's figures. In a later note[7] Heubner calls attention to a paper by Munk,[8] who in 13 analyses obtained a maximum percentage of only 1.55% and an average of 1.21%, which is almost identical with Forster's figures. A very complete review of the literature for the past few years on the subject of cow's milk in infant feeding will be found in a paper by Sommerfeld.[9]

Sterilization.—Troitzky[10] has found that complete sterilization of milk is not accomplished in less than 1½ to 2 hours at a temperature of 100° C., reckoned from the moment when this temperature is attained. The probability of infection of sterilized milk from exposure to the air, he has found, increases with each uncorking of the bottle after the first or second time.

For reasons that are at present undetermined raw milk affords a better culture-medium for microorganisms than sterilized milk.

Gärtner's Fat-milk.—Gärtner[1] reports further satisfactory results from his "fettmilch." In a series of 25 infants fed upon this diet for periods varying from 2 to 4½ months the average daily gain in weight was 20.6 g. (4⅜ oz. per week). The intervals of feeding are rather longer than those usually adopted: for the 1st week, 2½ to 3 hours; 1st to 2d month, 3 hours; 3d to 5th month, 3½ hours; and 6th to 12th month, 4 hours—with the usual 1 or 2 feedings during the night. In cases of feeble digestion, where a percentage of 1.5 to 1.7 of casein is not well borne, dilution with water or 6% milk-sugar solution, in the proportion of 2 of milk to 1 of water, gives a mixture containing only 1% of casein, but more than 2% of fat; while dilution of whole milk to a 1% casein standard leaves scarcely 1% of fat in the mixture. Somewhat different results have been obtained by Popper[2] in a series of 25 cases, in only 3 of which did increase of weight above the average occur during the administration of Gärtner's mixture. Of the remaining 22 cases, 14 actually lost weight, 4 neither gained nor lost, and 4 gained, but less than the normal average increase. It is noticeable that the great majority of the infants who lost weight were under 6 months of age, and in 8 cases in which the digestion was described as normal before this feeding was begun some form of indigestion was noted at the end of the period of trial. Thiemich and Papiewski[3] also have studied the effects of this preparation in cases of chronic dyspepsia in nurslings, and conclude that it is neither better nor worse than diluted milk—a verdict, it is fair to say, which is questioned by Gärtner[4] in the course of a long critical review of the literature bearing upon his milk-mixture. Keilmann,[5] on the other hand, taking his material from healthy new-born children, finds that in the first 10 days of life fat-milk preserves the original weight more nearly than any other artificial mixture of cow's milk. Healthy breast-fed children (181 cases) regained all but 18 g. of the initial weight in this period; infants fed on cow's milk 1 : 1 lacked 195 g., and those on cow's milk 1 : 3, 176 g.; while the fettmilch infants were only 66 g. behind. Encouraging results were also obtained in older infants. [For the purposes of this investigation it would seem no more than just that comparison should be made with better mixtures than simple diluted milk. The low fat-percentage of either of these dilutions gives an a priori advantage to any mixture richer in cream, and thus institutes a worthless comparison between fat-milk and a recognizedly unsatisfactory mixture.] Analyses of this mixture by impartial observers show a fairly constant average composition. Thiemich and Papiewski[6] found an average of 1.67% albuminoids and 3.2% fat, and Rupp[7] in 24 analyses obtained 1.46% casein and 3.2% fat.

Cautley's Modification.—Cautley[1] proposes a simple method for obtaining a modified milk that closely resembles human milk in composition. Taking an equal quantity of mixed cow's milk and a 10% solution of lactose, the whole is passed through a separator so arranged that the two outgoing streams are equal; it is thus divided into two equal parts, one of which contains practically the whole of the cream, and may be termed "cream milk," while the other contains practically no cream, and may be termed "skimmed milk." The composition of "cream milk" derived from a cow's milk containing proteids 4.0, fats 3.7, and lactose 4.4, was shown to be proteids 2.0, fats 3.5, lactose 7.2, which closely approaches the average of the analyses of breast-milk obtained by Leeds (proteids 2.0, fats 4.0, lactose 7.0). Another mixture of slightly lower proteid percentage (proteids 1.82, fats 3.7, and lactose 6.88) was well borne and digested by infants in the Belgrave Hospital for Children. An advantage claimed for the mixture is that it can be diluted without altering the relative proportions of the different solid constituents to each other. [The method seems to be an improvement upon the one recently suggested by Gärtner, in that the milk-sugar lacking in this mixture is already supplied in the process of preparation according to Cautley.]

Steffen's Mixture.—Wilhelm Steffen[2] calls attention to a milk-preparation which his father, the elder Steffen, used with great satisfaction for many years. The peculiarity of the mixture lies in the use of a weak veal broth as a diluent, the salts of which he believed played an important role in its digestion. The recipe for this broth is as follows: $\frac{1}{4}$ lb. of veal is boiled with $\frac{1}{2}$ liter of water for from $\frac{1}{2}$ to $\frac{3}{4}$ hour, and the loss is made up to the half liter by the addition of boiled water; this has been found to contain 0.2 to 0.3% of salts. Fifty g. of good whole milk are now diluted with an equal quantity of this broth, giving in the mixture a proportion of about 1.75% of fat. The deficiency in fat is made good by the addition of a teaspoonful of a 30% cream, and the sugar is brought up to normal by the addition of 3.8 g. of milk-sugar. The analysis of such a mixture gives fat 3.1%, casein 1.8%, sugar 6.2%, which agrees closely with accepted analyses of human milk and of Gärtner's fat-milk. Other dilutions may be made for the first weeks of life, or in later months when nearly whole cow's milk can be digested, and additional amounts of fat and sugar can be readily computed. Numerous experiments with this mixture in artificial digestive media have shown that it is precipitated in fine, feathery curds. When first taken into the stomach, as shown by regurgitation and by catheterization, the curds are larger and more cheesy, but still easily broken, but at the end of an hour the stomach contains only fine, feathery curds. The nutritive qualities of this mixture are said to be all that can be desired, and after 20 years' experience the author knows of nothing that promises better results.

Whey-and-cream Mixture.—Backhaus[3] reviews the various methods for preparing milk-mixtures, such as Voltmer's (which is very similar to the

[1] Lancet, Jan. 11, 1896. [2] Jahrb. f. Kinderheilk., Bd. xl. S. 421.
[3] Berl. klin. Woch., July 1, 1895.

better known "humanized milk" of Leeds), Rieth's albumose-milk, somatose-milk, Gärtner's fat-milk, and Kehrer's whey-and-cream mixture, and finds some room for criticism in each. With the last mentioned, however, he is nearly satisfied, and has therefore devoted much care and study to its improvement. By centrifugation he separates the cream from the milk. The milk may be sufficiently sterilized by "discontinued heating" (practically, pasteurization repeated several times). By the use of rennet under proper conditions a whey is obtained containing about 1% of albuminoids, consisting only of albumin, serum-protein, and lactoprotein, with about 5% milk-sugar. Condensation under lessened pressure to $\frac{4}{5}$ of the original volume yields a percentage of 1.25 albumin and 6.25 sugar. The addition of a proper quantity of cream gives casein 0.50 and 3–3.5 of fat, thus affording an analysis very closely resembling human milk. Several other variations may readily be made. The ash is slightly higher than in human milk, but less than in cow's milk. [The method fails to simplify the now well-known synthetic combination of milk-mixtures as brought prominently into notice in this country by the Walker-Gordon laboratories. Something seems to be gained, however, by eliminating a large part of the casein and increasing the more easily digested albumins, and by avoiding the necessity in general for adding milk-sugar.]

Lahmann's Vegetable Milk.—Höck[1] describes his experience in feeding 31 infants upon this product, which is made, according to Lahmann's formula, from almonds and other nuts with the addition of sugar. It contains fat 24.6%, plant casein 7.5%, cane-sugar 41.8%, plant dextrin 1.3%, calcium, potassium, etc. 0.68%, and water 24.44%. Used in combination with cow's milk in the proportion of 1 : 1 or 2 : 1, it is said to be precipitated in fine flocculent curds. Omitting 5 cases which died from conditions necessarily fatal, the remaining 26 cases showed only 2 in which weight was lost and 3 in which the daily gain was small. In the others the daily increment varied from 17 g. to 70 g., averaging for all these cases 30 g.

The Dresden Modification.—Worcester[2] describes the method of preparing milk for infants' feeding known as "the Dresden modification." The superiority of the method rests mainly upon the recognition of an essential difference between casein and lactalbumin. Lehman's analyses of breast milk and cow's milk, embracing the results of 10 years' study, show that while the casein of cow's milk is 3%, as compared with 1.2% in human milk, the albumin is as 0.3 to 0.5, so that the dilution of cow's milk with water sufficient to reduce the casein to the amount found in human milk gives a mixture containing only $\frac{1}{3}$ enough lactalbumin. Further loss is occasioned by the process of sterilization, since the coagulated albumin is wasted in the scum and by clinging to the sides of the bottle. The Dresden modification aims to make good this loss by the addition of the white of 1 egg to 1 pint of cow's milk ($9\frac{1}{2}$% fat), $1\frac{1}{2}$ pints of water, and 13 drams of milk-sugar. The egg should be washed, rinsed in absolute alcohol, and broken over a bowl or mortar, the white

[1] Wien. med. Woch., Mar. 7, 1896. [2] Boston M. and S. Jour., Sept. 19, 1895.

alone being taken. The milk-sugar is then slowly added and vigorously stirred with the egg-white, care being taken not to beat air into the mixture. To the paste so made 1½ pints of water are slowly added by constant stirring. This emulsion is strained through fine linen into the sterilized milk (when sterilization is desirable), previously cooled down below 100° F. Slight stirring or shaking will now complete the mixture, when it may be poured into the requisite number of nursing-bottles. In regard to this deficiency in lactalbumin, Leeds[1] states that in practice the results of adding egg-albumin are very disappointing, the operation of preparing and adding the egg-white to dilute milk being "troublesome and messy." He believes that as an attenuant butter-fat acts much more efficaciously, since it is almost perfectly coprecipitated with the casein, and cannot be removed from the clot by the most exhaustive washing—a result which he has shown occurs when the clot containing egg-albumin is subjected to the washing process. When cow's milk of average composition is diluted with half its volume of water and ⅛ part of the total in average cream added, the analysis gives—

	Fat.	Casein.	Albumin.
Cow's milk	3.75	3.00	0.75
Cream	18.80	2.00	0.50
Modified milk	4.13	1.74	0.44
Human milk	4.12	1.35	0.65

In this mixture, he contends, the insoluble proteid is about as much too high in amount as the soluble proteid is too low, and therefore the addition of albumin alone does not overcome the excess of casein. He therefore maintains that the most satisfactory method of overcoming the excess of insoluble proteid is by means of an incipient and very partial peptonization of the casein—a process which at the same time effects a practical sterilization of the mixture. [As a matter of clinical experience we can most heartily endorse the claims of Prof. Leeds for his "humanized milk," and have never encountered an example in which future digestion has been impaired by this often-asserted "method of encouraging inactivity, and consequent functional atrophy, of the peptic glands."]

DISEASES OF THE NEW-BORN.

Bacteria of the Intestine in the New-born.—Schild[2] has studied the bacteriology of the meconium of 50 new-born infants before any form of nourishment was administered. By making cultures from the rectum at various intervals after birth it was found that the meconium, which was sterile at birth, became infected at the end of 4 hours in the earliest instances, and not later than 20 hours in any of the cases, the average time being between the 10th and 17th hours of life. The following microbes were encountered: the porcelan-coccus of Escherich; the liquefying fluorescent bacillus, the nonliquefying fluorescent bacillus, the bacillus subtilis, the colon-

[1] Am. Jour. Med. Sci., Sept., 1895.

[2] Zeit. f. Hyg. u. Infectionskrank., 1895, Bd. xix. S. 113.

bacillus, the proteus, and a bacillus which the author was unable to classify. It is interesting to note that the bacillus coli communis was found very infrequently, and the bacterium lactis aërogenes never, thus confirming Escherich's earlier studies of the meconium. Under the conditions of the observations the mode of infection was by way of the anus, this being conclusively proved by the fact that in 3 cases subjected to disinfection and antiseptic dressing of the perianal region the meconium remained sterile for a longer period than in any of the other cases.

Double Monsters.—Jacobi[1] describes a double monster belonging to the class of pygopagus (see Fig. 100, p. 465) born under the care of Tynberg in New York City. The children died at the age of 5 months and were submitted to postmortem examination, the notes of which are given. The case is stated by Jacobi to be the fourteenth on record. Jacobi[2] also describes a case of ischiopagus which was seen in 1889 in the practice of Cooper of Groomesville, Ind. The children throve well, and, but for an attack of measles followed by a fatal pneumonia at the age of 8 months, bid fair to prove an exception to the statement made by Ahlfeld in his classic work[3] that no specimen of this monstrosity had been known to live more than a year.

Inanition-fever in the New-born.—Under this name Holt[4] calls attention to the fact, first noticed by McLane of New York, that pyrexia, often of marked degree, may occur in the first 4 or 5 days of life, dependent apparently upon insufficiency or absence of the breast-milk. He advises that the temperature of every new-born child should be taken during the first week. Diagnosis depends upon exclusion of all other causes of fever, coupled

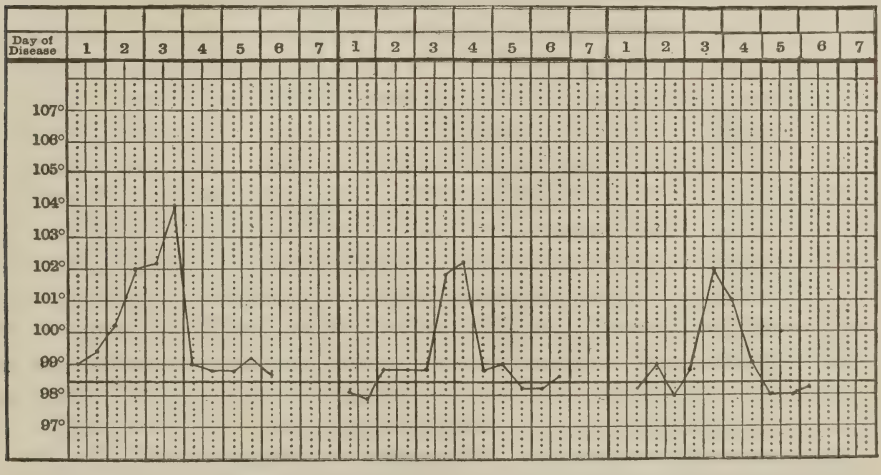

FIG. 127.—Charts of starvation temperature (Arch. of Ped., Aug., 1895).

with evident insufficiency or absence of the maternal breast-milk. Pyogenic infection, with which this fever might be confounded, rarely begins before the

[1] Arch. of Ped., Oct., 1895.
[2] Ibid., Mar., 1896.
[3] Die Missbildungen des Menschen, Leipzig, 1880.
[4] Arch. of Ped., Aug., 1895.

fifth or sixth day. The treatment is simple—water regularly every 2 hours, in quantities up to an ounce at a time if required by the thirst of the child. This should be given in every case when the temperature reaches 101° F. In case the temperature does not at once begin to fall, the infant should be put upon another breast or artificial feeding be begun. Cormier [1] also reports 2 typical cases due to the fact that the milk did not readily flow from the mother's breasts. Like Holt, he thinks the term "inanition-fever" an unsatisfactory one, although, as Holt says, it seems to emphasize the connection of elevated temperature with the fact that food is insufficient or entirely wanting. ["Starvation-fever of the new-born," or "starvation temperature," the latter a term suggested by Tucker, would express the condition more accurately.] Tuley [2] also refers to this fever, and gives 3 temperature charts, which are shown in the accompanying illustration (Fig. 127).

Icterus Neonatorum.—Schreiber [3] believes that, of all the theories advanced to explain the occurrence of icterus neonatorum, Quincke's is the only one that sufficiently explains all the facts. This theory attributes the condition principally to the persistence of the venous canal of Arantius; the biliary pigment absorbed from the intestine would pass directly by this avenue into the general circulation, and would not be retained, as in the adult, in the liver. Besides this principal factor, Quincke cited several subordinate ones—namely, the abundant production of bile through the destruction of red blood-cells, the scarcity of urinary excretion in the new-born, the richness of the meconium in bile-pigment, and the nontransformation, in the intestine, of bilirubin and urobilin, due to the absence of intestinal putrefaction in the new-born. These propositions Schreiber verifies from his own observation. Quincke cited 5 cases of persistence of the canal; the author has observed it in 7 cases, and calls attention to the results of Elsässer, who in 200 infants dying within the first 8 days found the canal closed in but 23, and in only 3 out of 78 which had perished very shortly after birth. Injection-experiments demonstrated that the blood passes through the canal, and by other experiments he was able to show that blood from the intestine passes by the hemorrhoidal veins into the vena cava without passing through the liver. Concerning the absorption of bile-pigment from the meconium, the author has shown by experiments upon dogs that, when bile was injected into the rectum, in all cases the bile-pigment appeared in the urine and the hemorrhoidal veins showed evidence of staining. The conditions of urinary excretion are also important, for it is evident that when little urine is passed in the early days of life the system is imperfectly relieved of the bile-pigments.

Sclerema Neonatorum.—A suggestive contribution to the etiology of this rare disease is to be found in the report of Schmidt [4] upon 3 cases which were most carefully studied. From the blood of all 3 children bacteria were isolated. The capillary vessels were crowded with bacteria, which were also found free in the connective tissue, in the parenchyma of the lungs, and in

[1] L'Union méd. du Canada, Oct., 1895. [2] Arch. of Ped., Aug., 1895.
[3] Berl. klin. Woch., June 24, 1895. [4] Zeit. f. Geburtsh. u. Gynäk., Bd. xxii. H. 2.

the subcutaneous fibrous tissues. Cultures in 1 case showed the bacillus proteus and also a liquefying germ. Further studies in this direction are necessary, but it seems likely that the disease may properly be considered an infection, though the point of entry, which was apparently not the umbilicus, could not be determined. As regards the health of the patients, the mother of 2 of these children had had 7 healthy children before and 2 subsequent to those manifesting the disease.

Tetanus neonatorum has received some attention in the literature of the year, especially at the hands of J. Lewis Smith,[1] who covers the subject very completely. Special interest attaches to the reports of the value of the antitoxin treatment, which are, as yet, meagre. Escherich, quoted by Smith, has treated 4 cases of the disease in the new-born by Tizzoni's antitoxin, one of which recovered; in the fatal cases septic inflammation of the umbilical cord was present, and all exhibited septic symptoms. In the case that recovered an injection of 0.3 g. was given on the third day and twice on the fourth. A case recorded by Firth,[2] beginning on the 7th day of life, received 4 injections—the first on the 8th day of the disease, 6 gr., the second and third on the 9th day, and the last on the 10th day, death from cramp asphyxia occurring 7 hours later. Smith believes that in order to be efficient the remedy should be used early, and that the hydrate of chloral, with perhaps one of the bromids, should still be employed. Local antiseptic treatment of the umbilicus is also highly important, since this is the common avenue of infection. An unusual case, in which tetanus followed ritual circumcision performed in the usual manner by the mohel, the wound being dressed without care, is recorded by Schirman.[3] This case recovered under the use of chloral by rectal injections, together with brandy, extract of conium, potassium bromid, and warm baths twice a day. Chloral and sodium bromid were also successful in a case reported by Carr.[4] Two fatal cases were seen by Rosenthal.[5] Marcy[6] has seen 8 cases, 7 of which, among negroes amid filthy surroundings, proved fatal. In the case that recovered tincture of solanum carolinense was pushed to narcosis; pilocarpin was also used, because the kidneys did not act sufficiently. Fronz,[7] in a resume of the cases of tetanus treated in St. Ann's Hospital during the past 30 years, gives the mortality at all ages as 44%, and that of tetanus neonatorum alone (14 cases) as 50 %. In the new-born sepsis is a more frequent accompaniment than in adult life, and dangerous complications, such as pneumonia and gastrointestinal diseases, are very apt to occur; new-born children are less susceptible to the tetanus toxin than are adults.

Melena Neonatorum.—A complete bibliography is appended to a paper on this disease by Lewis,[8] who adds 3 cases coming under his own observation to a series of 183 cases collected from the literature. A study of these statis-

tics does not show a sufficiently large number of cases in which hemophilia is definitely proved to be the cause to warrant the belief that melena is a manifestation of this diathesis. He remarks the fact that so little investigation has been recorded in reference to the condition of the cranial contents in fatal cases, and refers especially to the experimental study of Pomorski,[1] who succeeded in producing congestion, and possibly hemorrhage, in some portion of the alimentary canal of new-born rabbits by directly or indirectly injuring the vasomotor centre. Upon this ground the latter observer concluded that hemorrhage into the brain occurring during labor constitutes the principal factor in the causation of melena, and therefore he thought that the brain-hemorrhages which have frequently been found at autopsies upon children dead of melena are no longer to be regarded as complications, but as the cause of the other symptoms. To this view the author apparently gives assent.

Finkelstein[2] reports the case of a new-born infant dying of hemorrhage. In the organs a specific bacillus was found resembling the one found by Kolb in 3 cases of purpura hæmorrhagica, and called by him bacillus hæmorrhagicus. Cultures of this organism injected into rabbits caused a typical hemorrhagic condition. In the case reported the mother was syphilitic, but the author looks upon this disease as simply predisposing to the hemorrhagic diathesis, for which pyemic or septic infections are more directly responsible.

Gonorrheal Arthritis.—Haushalter[3] adds a new case to the few already reported in which arthritis was associated with purulent ophthalmia in a new-born infant. The right knee and left wrist were the joints involved; the knee was severely affected, presenting an abundant effusion containing polynuclear leukocytes and showing the presence of the gonococcus. A study of the 11 or 12 cases thus far recorded shows that there is no interrelation between the date of appearance of the joint-symptoms and the course of the primary infection. In the author's case the knee began to swell during the decline of the conjunctival discharge, while in Lindermann's patient the joint became affected after the cure of the ophthalmia. In the great majority of cases blennorrhagic arthritis in the new-born is monoarticular or oligoarticular; the knee is almost constantly involved, much more frequently than with older children or adults. The general condition is little affected and fever is absent. Cure results without deformity in little more than a month. Another case of the kind, affecting the hip- and wrist-joints, has been recorded by Griffon.[4] A third case, of American origin, has been seen by Tyrrell.[5] Both wrist-joints became affected 4 days after the beginning of the ophthalmia.

INFECTIOUS DISEASES.

Coexistence of Infectious Diseases.—An unusual coincidence of infections has been seen by Hand[6] in a boy of 4 years: 4 days after the

[1] Arch. f. Kinderh., Bd. xiv. S. 65. [2] Berl. klin. Woch., 1895, No. 23.
[3] Rev. mens. des Mal. de l'Enf., Oct., 1895, and La Méd. infantile, Dec., 1895.

[6] Arch. of Ped., May, 1896.

appearance of a profuse varicellar eruption diphtheric membrane was observed in the nostril, and 3 days later, after its prompt disappearance under antitoxin treatment, a profuse measles-rash appeared. This boy's brother, aged 7, who was suffering from diphtheria, and from whom the infection in the younger boy's case was received, entered upon a second attack of measles 10 days after his brother's attack and during his own convalescence from diphtheria. In the latter case it is interesting to observe that the diphtheria-bacillus continued to be present, but without membrane-formation, during the whole course of the catarrhal lesions of the measles. Whether this inactivity could be ascribed to the influence of antitoxin injections in the earlier treatment cannot be established, but under former modes of treatment a relapse of diphtheria might, with reason, have been expected.

Diphtheria.—Fränkel[1] replies to Hansemann's (see *Year-Book* for 1896, p. 539) objections against accepting the Klebs-Löffler bacillus as the essential etiologic factor in diphtheria. If, he argues, it is apparently not present in some cases of diphtheria, the inadequacy of our present methods are probably to blame. Its presence on healthy mucous membranes and elsewhere when there is no clinical diphtheria proves nothing against its etiologic significance in diphtheria, as individual predisposition must be taken into account. The conditions caused by animal-experimentation are, according to Hansemann, not diphtheria, but in Fränkel's opinion they bear a strong resemblance to human diphtheria. He believes that all of Hansemann's strictures on the Klebs-Löffler bacillus hold with equal force with regard to the tubercle-bacillus, the plasmodium of malaria, and many other organisms.

Pathology.—[Little that is new has appeared during the past year concerning the pathology of diphtheria, probably because our knowledge of this branch has been almost complete for some time.] The whole ground is thoroughly gone over by Councilman[2] and condensed into a series of conclusions admirably embodying our present knowledge of the subject.

Stokes[3] studied bacteriologically 9 fatal **cases of diphtheria in which antitoxin had been used,** and found in 8 of them a well-marked invasion of the blood by pyogenic cocci; in 5 cases the streptococcus was found in the liver, spleen, kidney, and blood of the heart, while the lungs were invaded with Löffler bacilli, streptococci, pneumococci, and staphylcocci pyogenes aurei, either alone or in various combinations.

Reiche[4] investigated **the kidneys** of 85 fatal cases before the antitoxin period, and found microscopic changes in the parenchyma, interstitial tissue, and Malpighian bodies. In the parenchyma there was cloudy swelling, followed by fatty degeneration, a few cases showing coagulation-necrosis. In 44 cases there was inflammatory proliferation of the interstitial connective tissue. The Malpighian bodies were always affected, but in varying degree.

Crocq[5] discusses the diphtheric **lesions of the nervous system** as

[1] Deutsch. med. Woch., Nov. 21, 1895.
[2] Boston M. and S. Jour., Sept. 5, 1895.
[3] Ibid., Dec. 12, 1895.
[4] Centralbl. f. innere Med., No. 50, 1895.
[5] Rev. mens. des Mal. de l'Enf., Sept., 1895.

experimentally produced in rabbits, in which a myelitis precedes the involvement of the nerves. Whether this occurs in man or not cannot be definitely determined, but it is probable that there are two types of diphtheric palsy, one being a localized neuritis and affecting the palate, pharynx, and larynx; the other, the generalized form, affecting the cord first and then the nerves.

Billings, Jr.,[1] has made a careful investigation of **the blood-corpuscles** in 36 cases of diphtheria, and studied the effect produced on them by the antitoxin. He also watched the effect of antitoxic serum on the blood of 15 healthy individuals. His conclusions are—1. The red corpuscles of the blood in diphtheria undergo a diminution in number in cases of moderate severity and in severe cases. Regeneration is slow. 2. The leukocytes are increased in number in all but two classes of cases, exceptionally mild cases and exceptionally severe ones. As a rule, the amount of leukocytosis is directly proportionate to the degree of severity of the case. The leukocyte-curve shows no correspondence to the clinical course of the disease. The number of leukocytes often remains higher than normal for days after all inflammatory phenomena have disappeared. The leukocytosis is similar in character to that seen in pneumonia and scarlet fever, the increase being in the so-called polynuclear forms. 3. The percentage of hemoglobin falls coincidently with the number of the red corpuscles, and to the same relative degree. But the regeneration of the hemoglobin takes place much more slowly than that of the red corpuscles. 4. In cases treated with antitoxin the diminution in number of the red corpuscles is much less marked than in those cases treated without it; in a majority of the cases no such diminution takes place. The leukocytes are apparently unaffected by the antitoxin. The hemoglobin is also much less affected in the cases treated with antitoxin, thus confirming the statement as to the red corpuscles. 5. In healthy individuals injected with antitoxin the red corpuscles show a very moderate reduction in number in about one-half the cases. The hemoglobin is correspondingly affected. The leukocytes are apparently unaffected by the injections. 6. No peculiar characteristic changes in the morphology of the corpuscles were to be made out. 7. It is improbable that any information of prognostic importance is to be gained by examination of the blood in diphtheria. 8. The antitoxin-treatment of diphtheria has no deleterious effects upon the blood-corpuscles. On the contrary, it seems to prevent degenerative changes which would otherwise be brought about.

Schlesinger[2] conducted similar studies in 24 children. In 21 of these cases, when examined before the injections, he found a manifest hyperleukocytosis, the degree of which varied between 1 to 71 and 1 to 275. This leukocytosis was not in relation with either the age of the child or the elevation of temperature present at the moment of examination; the influence of the gravity of the affection upon the leukocytosis was not constant, but in general the degree of hyperleukocytosis was more marked the graver the case. It was also observed that hyperleukocytosis diminished as the case proceeded to re-

[1] Med. Rec., Apr. 25, 1896.

[2] Arch. f. Kinderh., 1896, Bd. xix. S. 378.

covery, but persisted in the cases terminating in death. The influence of an injection of serum was manifested at first by a diminution of hyperleukocytosis, followed at the end of some time by an increase in the number of leukocytes, which did not always attain the degree observed before the injection.

Ewing,[1] working in the same field, arrived at essentially similar conclusions. He finds that the staining-reaction of the leukocytes is an accurate measure of the severity of the diphtheric infection, and variations in this reaction often precede changes in other symptoms. The multinuclear leukocytes found in the blood of favorable cases after treatment by antitoxin show increased affinity for gentian-violet. This change may be observed within 12 hours after the injection, and the failure of its occurrence is a very unfavorable prognostic sign. Antitoxin, within 30 minutes of its injection, causes a hypoleukocytosis, the reduction affecting specially the uninuclear leukocytes, while the proportion of well-stained multinuclear cells is increased. This action is due largely to the immunizing principle contained in the serum. He believes that the variations in the staining-reaction of leukocytes in diphtheria indicate that the nuclei of these cells contain a principle essential to phagocytosis and immunity in this disease.

An editorial in the Medical News of Feb. 1, 1896, suggests that the reason for **the tonsils** being the point of attack in 80% of all cases of diphtheria is that their situation is the most favorable for the microorganism to get a strong current of air, for it has been found that the germ develops rapidly under such conditions.

In examining **the blood-serum** of 14 children who, as far as known, had never had diphtheria, Orlowski[2] found that in a certain number the serum possessed the property of attenuating or even neutralizing the toxins of diphtheria, the degree of concentration of the immunizing substance being independent of the age of the child. In a note accompanying this paper Escherich adds that since these observations he had had the opportunity of observing a notable increase in the antitoxic power of the serum in one of these cases following a mild attack of diphtheria, and he therefore believes that the antitoxic power of the serum of individuals who have apparently never had diphtheria is attributable to the previous occurrence of a benign attack which had passed unperceived.

Diagnosis.—The diagnosis of diphtheria is discussed exhaustively by Hilbert[3] and by Williams.[4] Hilbert shows that while bacteriology extends the realm of diphtheria in one direction, it contracts it, although not to so great a degree, in another. The exclusion of the anginas not associated with the Löffler bacillus tends to raise the mortality of diphtheria, as the excluded cases present almost no mortality. Williams finds the bacteriologic examination of great value in two stages—very early in the disease, before the appearance of false membrane, and later, during convalescence.

Klein[1] states that he has been unable to see any connection between the size of the bacilli and the severity of the disease, having found the short bacilli in both mild and severe cases, the same being true of the long form. He prefers agar-plates as culture-media, especially in those cases of mixed infection in which the bacilli may be swamped in a luxuriant growth of cocci. When other media are not obtainable, Wright and Semple[2] recommend the use of a small quantity of antitoxic serum or the white of an egg, introduced into a small bottle and sterilized and coagulated over steam.

Koplik[3] calls attention again to the possibility of acute lacunar **tonsillitis** being at times due to the Löffler bacillus, and urges the importance of bacteriologic investigation.

Prognosis.—Bernhard[4] points out the uselessness of basing the prognosis on the presence or absence of **albuminuria.** The severity of an attack depends upon the patient's predisposition and the virulence of the bacilli. The prognosis can be partially determined by the morphologic elements in the urine—casts, renal epithelium, leukocytes, etc. having a bad significance, the worse the earlier they appear.

Roeth[5] describes fully the characteristics of the **micrococcus Brisou,** and urges the importance, from a prognostic standpoint, of its recognition in cases of angina due either to the Löffler or to the pseudodiphtheria bacillus, since its presence invariably denotes a favorable termination.

Statistics.—Vital statistics of diphtheria for London from 1891 to 1895 have been compiled by Dixey,[6] and for Boston, New York, and Brooklyn from 1880 to 1895 by Coakley.[7] In answer to the charges that the improved rate of mortality in the Berlin hospitals was due to a larger number of mild cases being sent for admission, Behring[8] publishes a table showing that the proportion of hospital cases to the total number of diphtheria-cases in Berlin has grown steadily smaller since 1892. A second table shows that, coincident with an extensive use of antitoxin in Berlin, both the relative and absolute mortality have fallen, the one nearly to, and the other to less than, one-half that of any one of the past 5 years.

Antitoxin.—[That the antitoxin, in itself, is practically harmless may be considered as well established, in view of the countless number of injections that have been made, with but a few fatalities attributed to its use; and in these cases the evidence is either so complete as to clear the injection of all blame, or so incomplete as to allow of no positive deduction. The unpleasant effects, such as polymorphous eruptions, fever, and painful joints, are clearly due to the serum and not to the antitoxin, and, as more concentrated serums are being put on the market, these sequels may be confidently expected to grow less in number, since the quantity of serum to be injected will thus be lessened in amount. It is to be hoped that some practical method may soon be found

[8] Deutsch. med. Woch., No. 38, 1895.

of obtaining the antitoxin apart from the serum, thus removing entirely the unpleasant effects due to the latter.] The nature of antitoxin is described, as clearly as is at present possible, by Klein.[1] He mentions as highly probable that the serum possesses two different actions, antitoxic and immunizing, which do not necessarily run on parallel lines, the serum prepared by injection of toxins possessing high antitoxic properties with relatively low immunizing power, while that obtained after injection of living cultures would be stronger for immunizing purposes. Bolton[2] has found **diphtheria-antitoxin in the blood of some horses** that had not been injected with the toxin, but the conditions determining this could not be ascertained. He has also corroborated Smirnow's work (see *Year-Book* for 1896), which showed that electrolysis is capable of producing antitoxin in the cultures of virulent diphtheria-bacilli. Smirnow[3] reports more extensively on his own work. Theobald Smith[4] discusses the conditions influencing the appearance of toxin in cultures of the bacilli.

Thomson[5] reviews the conditions and factors which enter into any reliable test of a remedy for an acute infectious disease. He shows that factors that would seem to prevent any conclusion being drawn are overcome by the mode and kind of evidence, and that the verdict, which is gradually being given from all parts of the world, is in favor of the antitoxin. He discusses the claim made by the opponents of antitoxin that the mortality everywhere should be lowered to a uniform rate if the antitoxin is to be considered at all a specific, and shows that this would require that antitoxin should be a body of definite composition and properties like a chemical compound, and that diphtheria should have equally unvarying characters everywhere. A specific in this sense of the term does not exist.

Welch[6] gives a **summary of all reported cases down to July, 1895,** covering 7166 cases treated mainly in hospitals, with a mortality of 1239, or 17.3%; 4294 of the cases were laryngeal, and gave a total mortality of 18.3%; 1167 of these came to operation (intubation or tracheotomy), and 434 died, a mortality of 37.2%, while 3127 not operated upon gave a mortality of 11.2%. Heubner,[7] in reporting 117 additional cases with a mortality of 10.2%, quoted official statistics which show that the mortality from diphtheria in Berlin, Dresden, Leipsic, Munich, and Hamburg for the first half of 1895 is both absolutely and relatively much lower than during any year covered by the records, although for Berlin the total number of cases was much larger. Monod,[8] investigating the mortality from diphtheria in over 100 large towns in France, found that the average number of deaths from diphtheria in each town for the first 6 months of each year from 1888 to 1894 was 2627. The corresponding number for 1895 was 904, showing an apparent saving in those 6 months of 15,000 lives. "Although," as suggested

in the *Lancet*, "climatic conditions or other unknown causes may have influenced this result to some extent, it seems unreasonable not to attribute this great diminution, which has gone on synchronously with the use of the antitoxic serum, in a large measure to the action of that remedy."

The Committee of the American Pediatric Society (Holt, Northrup, O'Dwyer, and Adams)[1] appointed to collect statistics of the use of **antitoxin in private practice** received reports from 615 physicians scattered in all parts of the U. S. and Canada. The committee in its reports excluded all doubtful cases that recovered, but included all doubtful cases that died. No new cases of sudden death immediately after the injection were returned, and but 19 cases seemed to be uninfluenced favorably by the injections, 9 of these being of doubtful diagnosis; 4 were complicated with measles; 3 were malignant cases; and in 2 the serum was of uncertain strength and of doubtful value; 3 cases were reported by the observers as being made worse by the injections. In all, 5974 cases were reported with a general mortality of 12.3%; moribund cases, or those dying within 24 hours of the injection, being excluded, it was 8.8%; 4120 cases injected in the first 3 days gave a mortality of 7.3%, or 4.8% if the moribund cases and those dying within 24 hours of injection are excluded. The mortality of 1448 cases injected on or after the fourth day was 27%. "The most convincing argument and, to the minds of the committee, an absolutely unanswerable one, in favor of serum-therapy is found in the results obtained in the 1256 laryngeal cases." In one-half recovery occurred without operation. Of the 533 intubated cases, the mortality was 25.9%. Bronchopneumonia occurred in 5.9%, in striking contrast to the proportion arising in hospitals. In a large number the heart's action was improved after the injection. There is very little, if any, evidence to show that the serum caused nephritis, but 15 cases in all dying from genuine nephritis. Paralytic sequelæ arose in 9.7%, showing that the serum has less effect on the nervous system than on any other part of the body. The society adopted the report and embodied its conclusions in the following resolutions: 1. *Dosage.*—For a child over 2 years old the dosage of antitoxin should be, in all laryngeal cases with stenosis and in all other severe cases, 1500 to 2000 units for the first injection, to be repeated in from 18 to 24 hours if there is no improvement; a third dose after a similar interval if necessary. For severe cases in children under 2 years and for mild cases over that age the initial dose should be 1000 units, to be repeated as above if necessary; a second dose is not usually required. The dosage should always be estimated in antitoxin units, and not by the amount of the serum. 2. *Quality of Antitoxin.*—The most concentrated strength of an absolutely reliable preparation. 3. *Time of Administration.*—Antitoxin should be administered as early as possible on a clinical diagnosis, not waiting for a bacteriological culture. However late the first observation is made, an injection should be given unless the progress of the case is favorable and satisfactory.

Adams[2] has compiled statistics from the District of Columbia, and finds

[1] Arch. of Ped., July, 1896. [2] Ibid.

that for the year ending June 30, 1894, there were 432 cases and 172 deaths, 39.8%. During the next 15½ months there were 311 cases, with 73 deaths, 23.44%. Of these, 135 were treated without antitoxin, with 47 deaths, 34.8%; the remaining 176 cases received antitoxin, 26 dying, 14.7%. The report is very thorough, giving careful analyses of age, race, kind of antitoxin, location of membrane, complications, and additional treatment.

A valuable treatise upon the serum-treatment of diphtheria is that embodying the observation of Baginsky at the K. und K. Friedrich Kinderkrankenhaus, Berlin, from March 15, 1894, to March 15, 1895.[1] The cases observed numbered 525, and the mortality, which was due entirely to 55 out of 192 light cases of general infection and 26 out of 30 septic cases, reached only 15% of the total number, or 36% of the serious cases in the two classes enumerated. A later report[2] adds the statistics of 203 subsequent cases with 21 deaths, 9.37%. A table[3] analyzes 6626 cases of diphtheria treated with antitoxin by 1349 physicians in different parts of the German Empire. It is of interest to note that 87% recovered, and in only 13% was benefit not observed after the injections. Washbourn[4] says that the majority of observers are agreed that the exudation clears off more rapidly with antitoxin than with any other method of treatment; that the temperature in diphtheria being of little importance as indicating the severity of the disease, the effect of the antitoxin is not of great moment, but if the fever is high it usually subsides rapidly; that there are no direct effects on the heart and kidneys, both, however, sharing in the general improvement; that if postdiphtheric paralysis appears more frequently, it is probably due to a survival of a greater number of severe cases; and that the antitoxin does not neutralize the effects of the invasion by streptococci or other bacteria. Gayton[5] does not think that the antitoxin can be credited with the lower rate of mortality, as it is not uniform everywhere. [This argument has been satisfactorily answered by Thomson[6] in another place.] Caiger[7] comes to rather different conclusions, finding from the use of antitoxin a lower mortality, a more rapid separation of the membrane, a relief from laryngeal and nasal obstruction, and, in those cases destined to die, a prolongation of life and greater comfort than usually obtains.

The Metropolitan Asylums Board of London reported[8] on the use of antitoxin in 2182 cases with 615 deaths, 28.1%. This is only slightly better than the figures for 1894, but the good effect of the antitoxin was most marked in laryngeal and tracheotomy cases, the rate of mortality falling respectively 20.2 and 21.2%.

In an article entitled "Clinical Observations on the Use of Antitoxin in Diphtheria, and a report of a personal investigation of this treatment in the principal fever hospitals of Europe during the summer of 1895,"[9] Winters

continues his opposition to the antitoxin, seeing not only no good in it, but positive harm. [If, as he says, the antitoxin does harm, and if the present low death-rate is due to the mildness of diphtheria, then the antitoxin must be holding up the death-rate to a certain extent, which would make it seem, then, that diphtheria at present should have an insignificant mortality if the use of antitoxin were to be abandoned.] Brannan[1] replies to Winters [both are attending physicians to the Willard Parker Hospital, N. Y.], correcting a number of statements as to clinical histories, medication, etc. The fatal cases in which postmortems were allowed were found to show pathologic changes not different from those formerly ascribed to diphtheria. White[2] gives as one reason why Winters saw no improvement in the cases at the Willard Parker Hospital that the improvement had already taken place, the patients having been admitted and injected from 12 to 24 hours before seen by Winters. Wesener,[3] having treated 100 hospital cases, concludes that antitoxin does neither more nor less in simple pharyngeal diphtheria than the usual local treatment; that it acts a little better in preventing a spread to the larynx or the need for tracheotomy if the larynx should be involved; that it is of no avail if the trachea or bronchi are involved; that it does not act any better in preventing or relieving sepsis; that its immunizing properties are not well established; that it is harmless. Furth[4] also treated 100 hospital cases, and concludes that nothing can equal antitoxin in its specific action. In private practice Schell[5] finds a remarkable improvement in the general condition of the patient shortly after its use. This improvement extends to all features of the case, including the pulse, so that some fellow-practitioners "who deny its value as a remedy for diphtheria insist upon its use as a cardiac stimulant." This is rather against the experience of Engel in Cairo,[6] who found a general depression with weakening of the heart for a short time after the injection. The general mortality of the antitoxin cases in Cairo (48 cases, 18 deaths, 37.5%), while higher than elsewhere, is yet lower than that which formerly held there.

Taking the statistics as a whole, Dana[7] finds that the percentage of palsies following diphtheria treated by antitoxin is somewhat lower than that which prevailed formerly, though there are some striking exceptions to this, and, apart from the figures, the general opinion is that the antitoxin does not lessen the frequency of these palsies. He further states that the fact that **diphtheric palsies** are not very much affected or not stopped "shows that the antitoxin, however effective as a whole, is not given in sufficient doses to prevent the specific effect of the diphtheria on the nervous system. The absolute and final test of the specific character of the diphtheria-bacillus, according to Dr. Sidney Martin, is, that it has the power to produce a poison which causes degeneration of the nerves and nerve-cells. He asserts that injections of either

[1] Med. Rec., June 20, 1896.
[2] Brooklyn Med. Jour., x. No. 2.
[3] Münch. med. Woch., Sept. 10, 1895.
[4] Ibid., July 23, 1895.
[5] N. Y. Med. Jour., Apr. 18, 1896.
[6] Berl. klin. Woch., Sept. 16, 1895.
[7] Med. Rec., Apr. 11, 1896.

the diphtheric albumose or of the toxin obtained from the membrane will cause these degenerative changes when injected into animals. He asserts, furthermore, that the injection of the antitoxin does not cause these changes; and, third, he asserts that when animals have received injections of diphtheric toxins, and then of antitoxin, the nerves are not affected. The fact, therefore, that persons who suffer from diphtheria and who receive antitoxin injections still develop postdiphtheric paralysis, shows at least that the antidotal action of antitoxin is not complete. It would not be fair to say anything more, and it may well be said that though this antidotal action is not complete, so far as the nerve-centers are concerned, it is sufficient in a large number of cases to prevent serious destruction of the organism.

Immunization.—Biggs[1] reports on the use of antitoxin in different institutions of New York for immunizing purposes, the appended table showing the almost wonderful results:

	No. of cases immunized.	No. of units of antitoxin administered.	No. of cases of diphtheria developing among those immunized between 1 and 30 days.	No. of cases of diphtheria developing within 24 hours.	No. of cases of diphtheria developing after 30 days.	No. of cases of diphtheria that occurred in the institutions previous to immunization.
New York Infant Asylum (1st immunization)	224	100 to 200	1 mild on the 19th day.	. .	6	107 cases in 108 days.
New York Infant Asylum (2d immunization)	245	125 to 225	1 mild on the 12th day.	. .	4	6 cases in 12 days.
Nursery and Child's Hospital	136	50 to 200	. . . .	. .	. .	46 cases in 90 days. 15 cases in 15 days.
New York Juvenile Asylum	81	150 to 250	. . . .	. .	. .	12 cases; 3 cases in 2 days.
New York Catholic Protectory	114	150 to 600	. . . .	1	. .	5 cases in 3 days.
Bellevue Hospital	11	175 to 225	. . . .	. .	. .	2 cases in 10 days.
Health Department Inspectors	232	150 to 250	1 mild on the 19th day.	3	3 {1 : 30 1 : 31 1 : 55	1 or more cases in more than 90 families.
Total	1043	. . . .	3	4	13	

Morrill[2] shows how immunizing injections of antitoxin obviated the necessity of closing the Boston Children's Hospital in the early part of 1895, a contingency which had arisen 3 times in 1894.

Eruptions and Accidents following Antitoxin. — Seibert and Schwyzer[3] experimented on animals to determine the **cause of the sudden deaths** reported after injections of antitoxin, and conclude that neither the antitoxic serum nor the phenol was responsible, but that air must have entered the venous circulation at the time of injection. The cases of Prof. Langerhans' child and Miss Valentine (mentioned in the *Year-Book* for 1896) are fully reported, the former by Strassmann,[4] the latter by Kortright.[5] Moizard and Bouchard[6] report a case of angina in which the Löffler bacillus could

[1] Med. News, Nov. 30, 1895.

[6] Ref. in La Méd. infant., Dec. 15, 1895.

not be found. Antitoxin was given and the throat was clear in 3 days. After 3 days more, vomiting, diarrhea, and fever set in, and the case terminated fatally 4 days later with convulsions, strabismus, dilated pupils, and coma—a result which Moizard attributed to the antitoxin, although it does not seem[1] to have caused him to oppose the use of antitoxin in diphtheria. Roux[2] criticises this report severely, as drawing conclusions on insufficient premises, and asserts that the harmlessness of antitoxin is shown by the fact that over 100,000 injections of the same serum had been made in France, in some cases much larger amounts being used than in the case reported. He says: "The serum may cause transient eruptions, but it is not dangerous, it does not kill. When you meet a case of angina with false membrane, make a culture, but do not await the result; 24 hours lost may mean a life sacrificed. Inject at once 10 c.c. of serum in ordinary cases, and 20 c.c. if it be severe or involve the larynx. You may then await the decision of the bacteriologist; your precautions have been taken in time. In the initial period the serum is marvellously effective. If the patient has not diphtheria, rest assured that you have in no wise compromised his welfare."

Dubreuilh[3] and Moussous[4] have discussed the postserotherapic eruptions. The former found that in some instances these followed the injections of serum from nonimmunized animals, that from dogs, sheep, or cattle causing them less often than from horses, mules, or asses. Moussous described 4 types: 1. A general or localized erythema like the eruption of measles, but without the other associated symptoms of coryza, etc. 2. An erythema like that of scarlatina, diffuse or in plaques, but lacking the phenomena of sore throat, etc. 3. A nettle-rash erythema. 4. A petechial erythema.

Additional Treatment.—Seibert[5] mentions the value of **antipyrin,** as first pointed out by Schweiger,[6] in cases of recurring dyspnea after extubation. **Pilocarpin** as a valuable adjunct to antitoxin, especially in septic cases, is urged by Sziklai,[7] Barsky,[8] and Saunders.[9] [A very complete series of abstracts of the literature of the diphtheria antitoxin, covering the years 1894 and 1895, will be found in the Jahrbuch f. Kinderheilkunde, Bd. xli., embracing nearly 100 pages of that publication.]

Measles.—Meslay and Jolly[10] report 4 cases of measles complicated with a **diarrhea** characterized by mucous and bloody stools; all 4 children died with bronchopneumonia. At the autopsy, besides the pulmonary lesions which seemed to have been the immediate cause of death, there were found ulcerations of the sigmoid flexure and rectum analogous to those of a true dysentery, but with small follicular ulcers that extended even to the small intestine and, in the most aggravated case, far up in the small gut. Rilliet

and Barthez have described a form of dysenteric diarrhea occurring under their observation twice after measles and 4 times after variola, but in none did the ulceration compare with that in one of the cases here recorded. Bolognini[1] describes what he considers an early sign of measles depending upon a sort of **peritoneal enanthem.** The child must be quiet and submit passively to examination, lying upon his back with thighs flexed. Standing by the side of the patient, the physician places his hands upon the abdomen, slowly and with gradually increasing pressure palpating the whole surface. There will be felt a fremitus or sensation of friction, not equally generalized, but distributed here and there over the abdomen, of fugitive character and difficult to detect. The author has sought for this phenomenon in 200 children, and has found it in all except 2 cases. The same exploration made in healthy children or in those not infected with measles has always been negative. He thinks the sensation is due to a slight alteration in the peritoneum, which he attributes to an internal eruption.

Bezold[2] has repeated the investigations of Tobeitz upon the **frequency of otitis in measles,** and concludes with this observer that otitis is a constant accompaniment of the disease. This conclusion is based upon an exploration of the contents of the tympanic cavity in a large number of rubeolous patients and upon a study of 16 specimens obtained from fatal cases. In the latter series mucopurulent, seropurulent, or purulent effusion was found in the tympanic cavity, antrum, and in the mastoid cells where these were sufficiently developed. Streptococci were found in half the cases, and white or golden staphylococci in the other half. The same organisms were found in about the same frequency in the exudate obtained by puncture of the drum in cases that recovered. This otitis begins early and is well marked on the 3d or 4th day after the eruption appears. Its course is benign, generally without marked symptoms; perforation is exceptional. As to the pathogeny, the author rejects the theory of infection through the Eustachian tube, but regards this otitis as a localization of the virus upon the mucous membrane of the ear, similar to that observed in the conjunctiva, bronchi, and intestine.

Scarlatina.—One of the topics for special discussion at the annual meeting of the American Pediatric Society in 1895 was scarlatina, and a number of interesting papers were presented. Attention may be drawn to the paper of Blackader[3] on "Some Forms of **Eruption Simulating Scarlatina,**" and the discussion elicited by it, which was opened by Dr. Griffith. This last-named observer covers nearly the same ground in a later paper on the same subject.[4] Louis Starr[5] reported a series of 6 cases, scarlatinal in character, the first presenting an intense but anomalous rash, without additional symptoms, followed by 3 other cases of similar eruption, each one adding a few details to the classic picture, until finally 2 cases occurring in the family of one of these patients stamped the series with the unmistakable diagnosis

of scarlet fever. Cases I. and II. occurred in the same family, 1 being taken ill 7 days after the other. Cases III., V., and VI. were also children of one family, 2 having been infected from the doubtful case. The rash in the first 4 cases presented many points of resemblance, the eruption being erythematous, punctate in places, and of a reddish-purple tint in some regions. Maculopapules were found as the rash extended. The desquamation was distinctly scarlatinal in type. In Cases I. and II. the temperature showed little deviation, reaching only 99° on the 3d day in the first, and ranging from 98.2° to 100° F. from the 1st to the 11th day in Case II.; the pulse was not above 90 at any time in either case. In Case III. vomiting occurred at the onset and temperature rose to 100° F. for one day. In Case IV. nephritic symptoms appeared during convalescence. Cases V. and VI. were attended with moderate elevation of temperature and increased pulse-rate for several days, and were distinctly scarlatinal in character. [These cases form an interesting series and demonstrate how difficult diagnosis may be in the milder cases.]

Wilson[1] saw in consultation a case of superficial **gangrene** of somewhat symmetrical distribution occurring 3 weeks after the onset of an attack of scarlet fever, and after apparent convalescence had become established. An irregularly symmetrical area of bluish-black discoloration of the skin occupied the nose nearly to its tip, and spread for 1 in. to the right and 1½ in. to the left side of the face. An area of similar discoloration, larger in size, also irregularly symmetrical, about 3 by 5 in. in diameter, occupied the renal region, extending down toward the buttocks. Epistaxis, continuing till death, 18 hours later, had begun just before the discoloration of the nose had shown itself. Symptoms of acute nephritis, followed for a time by almost complete suppression, had occurred 3 days before the gangrenous process had become manifest. No studies of the blood were possible. The case is very similar to 1 reported by Davies,[2] occurring 3 weeks after an attack of scarlatina. Secondary infection is suggested as a probable explanation.

From a study of two epidemics of scarlatina among soldiers in barracks Vogl[3] concludes that while **contagion** through a third person or through fomites or desquamation undoubtedly is efficient in spreading the disease, of greater importance in this respect is direct contact with the patient during the 3 to 5 days of the incubation-period. Lemoine[4] is of the opinion, which is shared by LeGendre and Sevestre, that the contagion of scarlatina is elaborated from the beginning of the affection, and, starting from what is its ordinary port of entry, the pharynx, spreads itself upon the cutaneous surface, the clothing, and surrounding objects. He believes that too much attention is paid to the disinfection of the skin, and not enough to that of the mouth, where, because of insufficient disinfection, the contagious principle may linger for a long time. He advises that antiseptic irrigation of the pharynx be kept up for some time after the disappearance of the angina.

[4] Rev. prat. d'Obstét. et de Pæd., Nov.–Dec., 1895.

A. Griffith[1] considers the occurrence of **secondary rashes in scarlet fever** in a paper based on his experience in the Bagthorpe Fever Hospital, Nottingham. Out of 2000 cases admitted for scarlet fever, there were 14 that suffered from what were considered as second attacks of the fever. If the author's view is to be accepted, and these later rashes are to be explained as indicated (agreeing with the experience of other large isolation hospitals), the question arises whether the illness is due to autoinfection, being properly termed a "relapse" or "recrudescence," or whether it depends on the presence of other patients in the same ward, some of whom may have fever of a more virulent character. It is not difficult to imagine that in a ward containing 12 to 20 patients, even with 2000 cubic feet of air-space each, the amount of infection is very large, the virulence being possibly increased by aggregation as well as by the uniform temperature of 60° F.; nor is it difficult to suppose that those who have had mild attacks from a small dose of poison in the first place, rather than from their insusceptibility, may be insufficiently protected against a larger dose of a more virulent infection. If this is the correct explanation, it would point to the inadvisability of aggregating fever cases in large wards, and still more to the fault of the usual plan of placing mild and medium, if not severe, cases in the same wards and under the same nurses.

A careful investigation of the conditions under which **"return" cases of scarlatina** may appear has been lately made by Chalmers[2] from the statistics of the three fever hospitals of Glasgow. During 1894, 2593 patients were sent to their homes after an attack of scarlet fever, and in 70 of the houses fresh cases of the disease appeared. In 93% of these cases the new infection appeared within 2 weeks after the convalescent's return; in 19% it seemed to depend upon the recurrence of desquamation or of discharge from the nose or ear in the original patient. In the remaining cases no such cause was found, so that it seems probable that the returned patient may remain infective, although he is entirely free from desquamation and shows no trace of the disease. There appears to be some evidence of the connection of this latent infectivity with the amount of air-space allotted to each patient in the ward, there being apparently a greater tendency to the communication of secondary infection when the original patient has been treated in an overcrowded ward. Whether this infective power lies in the breath or in the skin, the practical conclusion is adduced that a patient should be isolated from other children for some time after his return from the hospital.

Considerable interest has been aroused by the experimental use of **Marmorek's antistreptococcic serum in scarlatina.** While the pathogenic germ of this disease is not definitely known, it has been generally accepted that a streptococcus is encountered in all cases, and this fact has suggested to Josias[3] the employment of the serum as a prophylactic against the more serious secondary complications. His earlier experiments were made upon 49 cases with a small dose of a serum derived from sheep. No phenomena but a slight

[1] Quart. Med. Jour., Oct., 1895. [2] Lancet, June 22, 1895.

[3] Tribune méd., Sept., 1895.

urticaria in a number of cases occurred after several days. The course of the disease seemed in no way modified, and implication of the cervical glands and of the kidneys was not prevented. Later[1] a more active serum from the horse was tried in a second series of 96 cases. Ten c.cm. of this serum were given at admission, and the injections repeated according to persistence of fever, exudation, or albuminuria. Without entering into an analysis of the results, we can briefly state that they have been disappointing. In the first series, as compared with the results in 365 cases treated according to the usual methods, the mortality was noticeably less (5.81% to 2.08%), while in the second series it was practically the same. Josias believes that no advantage over the older methods has been demonstrated; that neither the course nor temperature-range has been affected; and that no influence upon the diverse suppurative processes liable to occur during the course of the disease has been observed. He finds it difficult to explain why the streptococcic complications of scarlatina seem to be so little affected by Marmorek's serum, which experience has shown to be so marvellously efficacious against most streptococcic affections. He suggests a possible explanation in a curious observation recently reported by Méry,[2] who found in the blood of a scarlatinous child a streptococcus upon which Marmorek's serum had absolutely no effect. If, in addition, it be remembered that researches in Nocard's laboratory have shown the existence of two infectious streptococcic diseases in the horse, one of which is absolutely refractory to the action of Marmorek's serum, while the other is prevented by the injection of a small dose of this agent, the conclusion is at once almost irresistible that the streptococcic complications of scarlatina are due to a special variety of the organism altogether different from the streptococcus of erysipelas, and against which the serum of Marmorek is powerless.

Baginsky's[3] experience, however, is apparently more encouraging, though the test cannot be regarded as conclusive, since the quantity of serum available was small and required economical use; 48 cases were treated with a mortality of 7, or 14.6%. This compares more than favorably with the mortality of 238 cases of the same epidemic treated in the K.- und K.-Friedrich Kinderkrankenhaus in 1895, which equalled 24.9%; from 1890 to 1894, inclusive, the yearly mortality varied from 22.6 to 34.4%. Local infiltration about the point of injection sometimes occurred, and urticaria in several of the cases.

In 33 uncomplicated cases Lemoine[4] found no **streptococci** in the blood during any stage of the disease. In 2 hemorrhagic cases, however, 1 of which was fatal at the end of 48 hours, the other after 5 days, blood from the margins of sanguineous effusions gave pure cultures of a streptococcus. As in the researches of D'Espine and Marignac, this streptococcus coagulated milk and flourished on potato. From these facts Lemoine argues that the presence of the streptococcus in the blood is accidental and due to complications of the disease. Of 22 cases of nephritis, this streptococcus was found in the urine of all, the angina having been of grave character; while of 11 cases in which

[1] La Méd. mod., May 16, 1896.
[2] Soc. de Biol., Apr. 18, 1896.
[3] Berl. klin. Woch., Apr. 20, 1896.
[4] Soc. méd. des Hôp., Mar. 20, 1896.

the urine remained normal, the streptococcus was found in but 1. He therefore regards the renal complication as a secondary infection, most often the result of special virulence of the streptococcus developed in the fauces.

Excessively high temperature in the course of this disease has been observed by Depasse[1] in a child of 16 months. On the 12th day a temperature of 107⅗° F. was recorded, and was maintained for 70 hours, despite active antipyretic treatment by means of antipyrin and frequent cold baths.

Dauban[2] cites a remarkable observation of Péron in which a **scarlatinal arthritis** was immediately **followed by** a well-characterized progressive **chronic rheumatism.** The scarlatina had occurred at the age of 12 years, and, when examined at the age of 23, the patient presented a large number of deformities affecting principally the upper extremities. The lesions, however, were not exactly the same as in a true nodose rheumatism, since the synovial membranes of the joints and the fibrous tissues surrounding them were alone affected, and considerable benefit from treatment was obtained.

Priestly[3] details the results of his investigation of the use of **eucalyptus oil** as a disinfectant in scarlet fever—a method of treatment originally proposed and enthusiastically advocated by Curvengen of Teddington. The treatment consists in carefully rubbing the whole body 3 times a day for 3 days with a mixture composed of the oil of eucalyptus, thymol, camphor, and other aromatic disinfectants in solution. After 3 days one rubbing each day is given after a warm bath. The results reported by the author are extremely good. Cases treated in the hospital are discharged 1 week earlier than ordinary cases, desquamation being distinctly hastened by its use. Seibert[4] has found that inunctions of a 5% ointment of **ichthyol** have been followed by most marked effect upon the local condition of the skin, producing rapid decline of fever and improving the general condition. The swollen, red skin shrinks and turns pale brown, temperature declines 3 to 4 degrees within 2 hours, and the nervous, itching, peevish child becomes quiet and usually goes to sleep. While he does not believe that the treatment has any specific effect upon the character of the general infection in scarlatina, so as to change a malignant case into a mild one, he is convinced that the ointment applied in these cases destroys most of the bacteria causing scarlatinous dermatitis, and thereby materially aids in overcoming the general infection.

Typhoid Fever.—[The occurrence of typhoid fever **in young children** has been discussed considerably in the past 2 years, and the general testimony has been that the disease is extremely rare during the first 2 years of life and uncommon under 3 years.] Strong evidence in support of this view has been brought forward by Northrup,[5] who quotes the statistics from the New York Foundling Hospital, the New York Infant Asylum, and the Philadelphia Children's Hospital. During the past 20 years at the New York Foundling Hospital, where 1100 of the 1800 children under its care

[1] Rev. mens. des Mal. de l'Enf., June, 1896.
[2] Thèse de Paris, 1895.

[4] Arch. of Ped., Sept., 1895.
[5] Ibid., Dec., 1895.

are boarded out in the city and surrounding country, being returned to the hospital when ill, not a single case has been seen by Drs. Northrup, O'Dwyer, and J. Lewis Smith, as confirmed by the 2000 autopsies of Dr. Northrup.

In **the Stamford, Connecticut, epidemic** of May, 1895, which was due to an infected milk-supply, 406 cases of all ages occurred, 194 in children under 15 years and 68 under 5 years. Of this number, 4 cases in infants, aged respectively 13 months, 22 months, 16 months, and 22 months, are recorded by Northrup [1] in a later paper, together with 3 other cases aged 27 months, 30 months, and 3 years. These 4 cases under 2 years of age were the only ones recorded out of the total of 406, and not only go to bear out the fact of insusceptibility at an age when other intestinal diseases are very frequent, but also show that, as Northrup states, this insusceptibility is only "overcome by the overwhelming poison present in a severe epidemic." All of the 7 cases here referred to had been exposed directly to the infection by drinking the milk, and in some instances by being in intimate relation with others sick of the disease. In this same paper Northrup calls attention to an important point in the morbid anatomy in young children by presenting side by side the specimens from the only fatal one of these cases and the ileum of another child dying in convulsions after an illness of only 36 to 48 hours. In the latter case there was a history of gross error in diet, and typhoid fever could not have been considered. In the fatal typhoid case only two of Peyer's patches at the lowest part of the ileum were prominently swollen, with moderate swelling of the solitary follicles higher up in the ileum and in the colon. In the case of acute indigestion the swelling of Peyer's patches and the mesenteric glands was much more noticeable, though the appearances were far from being as pronounced as in other similar cases that had been observed by the author. These postmortem findings, he says, in the absence of a clear clinical history, must not be interpreted like similar lesions in the adult. He refers to a more striking illustration in Rotch's recently published text-book.[2] He concludes that in the young child typhoid appears under the same guise as in the adult, and that the characteristic eruption is one of the most valuable points toward a diagnosis; and as a parting warning he says: "Beware of typhoid without lesions and lesions without clinical history of typhoid."

A house-epidemic affecting 11 children between the ages of 3 and 12 years is described by Bond.[3] He believes that care should be used to prevent accumulations of ill-digested, foul, and irritating food-residues in the bowel at any time from the inception of the disease far into convalescence. At the beginning the bowels should be thoroughly cleaned out. Later, if there is not depressing diarrhea, he does not hesitate to give occasional $\frac{1}{10}$-gr. doses of calomel or, if constipation be present, small doses of Epsom salts (ʒss to ℥j) to secure a daily evacuation. The results of this plan of keeping the bowels open are stated to have been very favorable. [General teaching, however,

[1] Arch. of Ped., Jan., 1896. [2] Pediatrics, Philadelphia, 1896.
[3] Va. Med. Monthly, Jan., 1896.

has been against the use of purgatives except at the very onset, lest perforation at the site of deep ulcers be induced by the increased peristalsis.]

By far the most **extensive series of cases** of typhoid fever in children reported by one observer in recent years is that drawn from the records of the Boston City Hospital by Morse;[1] 284 cases are analyzed, including, under 5 years, 3 cases; from 5 to 10 years, 77 cases; and from 10 to 15 years, 204 cases. The insignificant number of young children, as compared with that given in Vogel's 1017 cases and in the 686 combined cases of Henoch, Roeth, Earle, Archanbault, Smidt, and Wolberg, is explainable by the fact that small children are rarely taken at the hospital. While this to some extent diminishes the value of the proportions at other ages, the general conclusions which draw a contrast with adult cases are not affected.

Noyes[2] again emphasizes the fact that in early infancy typhoid fever in a typical form is **rare in this country,** though not uncommon abroad. It is in a mild or abortive form that it must be looked for here if we wish to separate it from other intestinal or meningeal diseases that may appear. He points to the significance of Vincent's[3] studies of the later and secondary condition of infection by a combination of Eberth bacilli and streptococci, and concludes that when a case is severe and prolonged we may see in it not the result of the simple infection by the typhoid-bacilli, but a complication by other pathogenic bacteria.

Freund and Levy[4] have observed an interesting example of **intrauterine infection.** The mother aborted about the sixth month of pregnancy during the fourth week of typhoid fever. The delivery was conducted under strict antiseptic precautions for the purpose of submitting the fetus to a thorough bacteriologic examination, which was begun 20 minutes after birth, the fetus having died 15 minutes after the cord was cut. Cultures were taken from the placenta, the pulp of the spleen, and the blood from the heart, and in all three the bacillus of Eberth was found. Cultures from the superficial parts of the placenta and from the vernix caseosa remained sterile, thus excluding the possibility of accidental infection. The anatomic lesions of the fetus were confined to a slight hypertrophy of the spleen, which appeared a little softer than in the normal state. The patches of Peyer were not ulcerated and the intestinal mucous membrane was normal. The absence of specific lesions, which is a condition common to all cases of intrauterine infections, is attributed by the author to two facts—to the septicemic form which all such intrauterine affections exhibit, and to the absence of functional work in the special organ which in the adult the microorganism chiefly attacks.

König of Pittsburg[5] speaks highly of **guaiacol** internally as an antiseptic in the typhoid fever of children. He employs the following formula: ℞. Guaiacol, f℥j; glycerin, f℥ij; alcohol, f℥ij.—M. Sig. 1 to 6 drops in whisky and water every 2 hours, according to the age. This treatment is

[1] Boston M. and S. Jour., Feb. 27, 1896.

[5] Jour. Am. Med. Assoc., Oct. 5, 1895.

continued throughout the course of the disease, the dose of guaiacol being increased or decreased according to the severity of the symptoms. He states that under this plan of treatment intestinal antisepsis is evidenced by the slight degree of tympanites, absence of sordes, and especially by the character of the stools, which are much less frequent and practically destitute of the very disagreeable odor that characterized the passages of patients before the introduction of treatment directed toward intestinal antisepsis.

Varicella.—Semtschenko[1] publishes a **study of 872 cases** of varicella observed in 12 epidemics during 15 years at the Hospice des Enfants-assistés in Kasan. In all the cases the existence of a period of incubation was observed, varying from 3 to 26 days, the average observed in the largest number of cases being 16. The period of incubation passed ordinarily without symptoms, though in a certain number of cases failure of appetite, troubled sleep, or bad humor could be noted, with thirst, pulse-frequency, and slight elevation of temperature. Fever varied with the intensity of the eruption and the gravity of the infection, lasting 24 hours in 178 cases, 2 to 3 days in 481, 4 days in 109, and 5 to 6 days in 15. The highest elevation of temperature was ordinarily observed on the evening of the second day after eruption. Second attacks were observed very rarely; in 14 cases the interval was 8 to 18 months; in 5 other cases there were 2 subsequent attacks of the disease. Among the complications the most frequent was furunculosis; next in order was submaxillary and cervical adenopathy (27 cases) alone, or combined with inguinal adenopathy (5 cases), suppuration of glands being noted twice. Other complications were: Erysipelas (15 cases); osteitis (34 cases), sometimes associated with synovitis (4 cases); and otitis media (17 cases). Nephritis was noted in 5 cases, 3 of which terminated in death from uremia. Albuminuria, sought for in 251 cases, was found in 42.

Marfan and Hallé[2] record 2 rare instances of **suffocative laryngitis** complicating varicella. The first case, an infant of 3 years, showed marked evidences of laryngeal obstruction of so severe a grade that antitoxin was administered under the idea that the case was one of primary laryngeal diphtheria. The first vesicles of varicella now appeared, with aggravation of the dyspnea, calling finally for tracheotomy; the child recovered. Cultures proved the absence of diphtheria-bacilli. In the second case, a weakly infant of 9 months which died on the seventh day from acute diarrhea and bronchopneumonia, antitoxin was also given unnecessarily. The autopsy showed a small round, deep ulcer at the posterior margin of the right vocal cord. In these 2 cases a varicellous exanthem of the laryngeal mucous membrane had determined a stenosis, giving the clinical picture of a true croup. The only case of varicella involving the larynx previously reported is that recorded by Boucheron in his thesis,[3] in which the affection took the aspect of a spasm of the glottis without symptoms of laryngitis. The case terminated fatally by

[1] Ejenedelnik, 1895, No. 28, p. 421. [2] Rev. mens. des Mal. de l'Enf., Jan., 1896.

[3] Etude sur les Complications respiratoires de la Varicelle et Relation d'un Cas de Varicelle du Larynx, Paris, 1893.

suffocation during an access of the spasm. The authors conclude that involvement of the larynx in varicella occurs early, about or shortly after the appearance of the eruption—a point that serves to distinguish it from secondary and unrelated infections. Anatomically, the laryngitis is characterized by small ulcerations, circular, few in number, seated usually upon the true cords. About these ulcers the mucous membrane may be the seat of hyperemia more or less intense and extended. These two lesions explain the two forms under which the complication occurs, as is shown by the authors' cases on the one hand and by Boucheron's on the other.

Pertussis.—Paralysis due to hemorrhage occurring during a paroxysm of whooping cough is not an extremely rare accident, but is almost always manifested as a more or less complete hemiplegia, as is illustrated by 2 cases reported by Theodor,[1] one of which was followed by chorea. Palsy of the sixth and seventh cranial nerves, as observed in a case reported by Craig of Londonderry,[2] therefore demands mention, if only for its rarity. In this case there was left facial palsy, partial only as regards the orbicularis palpebrarum and the frontalis, and complete palsy of the external rectus oculi. The lesion was believed to be a venous hemorrhage involving the nucleus of the sixth nerve, affecting also contiguous fibres of the seventh.

Marfan[3] in an experience of 40 cases of pertussis has found **bromoform** superior to antipyrin or belladonna. His formula is: Bromoform, 48 drops; oil of sweet almonds, 20 g.; gum adragante, 2 g.; gum arabic, 4 g.; cherry-laurel water, 4 g.; and water sufficient to make 120 c.c.—Mix the bromoform and oil and vigorously agitate; then add the other ingredients. A coffee-spoonful contains 2 drops of bromoform. For infants under 6 months the daily dose, given in 3 portions, is 2 to 3 drops; over 6 months, 3 to 4 drops. From 1 year to 5 he gives 4 drops for each year of the age, and from 5 to 10 years the initial daily dose is 20 drops. These doses may be gradually increased till doubled. His experience does not bear out the claim made by Stepp that the duration of the convulsive stage is shortened. Eaton's[4] plan for giving bromoform is to begin with a known safe dose and then rapidly push it to the limit of evident relief of symptoms. He orders it to be administered by simply dropping it in a little water. An important fact to which he calls attention is that a fluidram contains about 360 drops of bromoform, owing to the high specific gravity.

Ullmann[5] strongly advocates the fresh-air treatment of pertussis. For sake of comparison between the period passed out of doors and that passed in the house, he has noted in a series of cases the hours spent in each, and the number of paroxysms and their intervals under the two conditions. From these data he concludes that the fresh-air treatment is one of the most efficacious, if not the only one, for the management of a case of whooping cough. The child should pass the entire day out of doors, not only in the warm season, but

[1] Arch. f. Kinderh., Bd. xx. S. 219.
[2] Brit. Med. Jour., June 13, 1896.
[3] Rev. mens. des Mal. de l'Enf., Apr., 1896.
[4] Jour. Am. Med. Assoc., Oct. 12, 1895.
[5] Jahrb. f. Kinderh., Bd. xl. S. 39.

even at all times of the year, provided it be not stormy. It is considered only necessary to prevent the child from running or talking or otherwise provoking an access of coughing. Contrary to general teaching, he advocates the open-air exposure of the patients even when there is bronchitis or bronchopneumonia, the only precaution being to have the little ones well wrapped up. This plan he has practised with infants a year old suffering from grave bronchopneumonia. During this treatment the author employs neither a specific nor a narcotic. In the presence of very grave bronchopneumonia he prescribes spirits of camphor as an expectorant.

A new drug for the treatment of pertussis is **phenocoll hydrochlorate,** which has been prominently brought to notice by Vargas.[1] This observer reports 42 cases successfully treated. The dose varied from 0.07 g. to 2 g. daily, given usually in mucilage or in water, in which it is soluble in the proportion of 1 to 17. The action of the drug seems to be not as a germicide, but as a sedative to the trigeminus and laryngeus superior nerves. For the first 2 weeks this effect is only a passing one, for on suspending the remedy the paroxysms gradually return. He makes an energetic protest against the open-air treatment, arguing that the child does not obtain the necessary rest, and that lung-complications are very apt to appear, owing to the changes of temperature to which the patient is exposed. A second great danger is the impossibility of isolating the child under this mode of treatment. In all of the 42 cases treated the good results were noticeable within 12 hours, but in some cases the number of paroxysms was reduced only on the following day. Even in very young children and in complicated cases this remedy produced neither nausea, vomiting, collapse, nor other disagreeable consequences. The drug is very quickly excreted, elimination beginning within 20 minutes after taking and being completed in 15 to 20 hours.

Vincenzo[2] reports satisfactory results from **vaccination** in 13 out of 14 cases of pertussis. [Favorable testimony for this method of treatment continues to be received from time to time, much of it indeed from Italy. It is a simple expedient, and if done with antiseptic care should add no gravity to the case. If the child has never been vaccinated, it is stated, the best effects may be hoped for; but the operation should still be tried with children already vaccinated, in the hope that the power of the first inoculation may have become weakened sufficiently to permit of a new "take."]

Kourlow[3] gives an elaborate description of the **ciliated ameba** first observed by Deichler in 1886, and considers it the specific organism causing pertussis. It is best detected, he says, in the early stage, before the mucus has become purulent. It is a unicellular organism, varying in size from half that of a red blood-corpuscle to that of the white corpuscle, or even larger. One side or two opposite sides are bordered with long cilia, which are in constant motion, producing rapid oscillatory movements. It may be readily stained with Ziehl's carbol-fuchsin.

[3] Vratch, No. 3, 1896.

Tuberculosis.—Two cases of acute tuberculosis lighted up by an attack of **typhoid fever** are recorded by Haushalter.[1] The patients were brothers aged 4 and 7 years. The younger, who was first affected, had a severe attack of typhoid, succeeded by apyrexia of several days' duration, and then followed the evolution of acute tuberculosis of the lung simulating a relapse of typhoid. The autopsy showed the lesions of typhoid fever and those of a miliary tuberculosis of the lungs, the origin of which was found in long-standing disease of the bronchial glands. The elder boy, who had had Pott's disease since the age of 3, was taken ill of typhoid 3 weeks after his brother. On the 12th day an abundant intestinal hemorrhage occurred, followed by a tendency to collapse, and death suddenly on the 20th day. Typhoid ulcerations were found in the bowel, and in the right lung an acute tuberculosis. The author refers to the great difficulties in exact diagnosis in such cases, and advises a guarded prognosis of typhoid fever in children disposed to tuberculous disease or in those harboring torpid tuberculous lesions.

In commenting on a case of intestinal tuberculosis in a baby of 16 months due to ingestion of the bacillus from a local tuberculous lesion of the gum, Marfan and Apert[2] refer to the **rarity** of this intestinal lesion **in the first 2 years of life.** They quote Wiederhofer's statistics, which show that it forms only 8% of all tuberculous lesions at this period of life, as opposed to 28% in the period from 2 to 15 years of age. They state that intestinal lesions may be found, first, in an acute miliary tuberculosis, as small gray granulations in the mucosa, of hematogenous origin; second, in cases of the pulmonary disease with cavities, assuming the common ulcerous form seen in adults; and, third, after the ingestion of tuberculous material, usually milk-food, where there may be no lesion of the mucosa, the bacillus having traversed it to find a suitable nidus in the mesenteric glands; or scattered submucous nodules may be found, pea-sized, filled with gray or cheesy, softened material, limited by a delicate fibrous covering, and corresponding in position with the affected mesenteric glands.

Manicatide[3] has found **the spleen** affected in 10 out of 12 cases of tuberculosis of children examined after death; 8 showed distinct macroscopic evidence of the disease, and in the remaining 2 its presence was evident in microscopic preparations. Some of the cases examined had presented a more or less generalized tuberculosis, but in several of those showing lesions in the spleen the disease elsewhere was of quite limited extent. In all the cases examined the spleen was increased in size, even when the evolution had been slow: this observation confirms the views of Landouzy and Henoch, who have always insisted upon the hypertrophy of the spleen in tuberculous children. Histologically, if the evolution of the disease has been rapid, gray granulations predominate, with congestion of the organ; if the progress has been less rapid and the child is of more advanced age, the tubercles are caseous and the connective tissue increased. In only 1 case was amyloid

[1] Rev. méd. de l'Est, June 1, 1895. [2] Rev. mens. des Mal. de l'Enf., June, 1896.
[3] Ibid., Feb., 1896.

degeneration of the small vessels found. Giant cells are numerous, but bacilli scarce. Contrary to the general conclusion reached in the recent thesis of Benzançon,[1] Manicatide has found that tubercles develop not only in the interior of the Malpighian corpuscles, but may be found often in the pulp, in the interstitial tissue, about the veins, and even in the capsule of the organ.

Zappert[2] recognizes 3 groups of pathologic changes which in the course of a **tuberculous meningitis** may produce hemiplegia. These are—1. An exudation upon the convexity of a hemisphere; 2. A focus of softening or inflammation in the capsular region; 3. Exudation upon the cerebral peduncle. He records 7 cases and quotes extensively from the literature.

Gaffié[3] has used **tuberculin** in children for diagnostic purposes with very satisfactory results in 20 cases of pulmonary tuberculosis. The dose employed, $\frac{1}{20}$ mg., gave rise to no complication and occasioned only slight inconvenience, such as dryness of the mouth, headache, constriction of the chest, and redness of the face.

Referring to the difficulties in the **diagnosis of pulmonary tuberculosis** in children, Kossel[4] states that he has frequently made the diagnosis of a pulmonary lesion by a bacteriologic examination of the stools, even in cases of children whose intestines were unaffected and functionating normally. The paper also contains a valuable study of the pathologic anatomy of the disease based upon the autopsies of 23 cases in infants from 2 months to 5 years of age, and in 17 other cases where the disease was not recognized till the autopsy.

Klebs[5] states that **antiphthisin** offers most favorable results, especially in the tuberculous affections of childhood. The selection of cases, however, is of the greatest importance, and the fullest benefit can be expected only when cases are selected which present neither septic complications nor conditions of exhaustion and marasmus. Cases will also be found in which, on account of the great extent of the purely tuberculous disease, failure may result. These limitations, however, suggest that the remedy should be employed in the earlier periods of the disease, and that valuable time should not be lost in the employment of symptomatic treatment only.

Syphilis.—Robinson[6] classifies **the joint-diseases** in children due to syphilis as follows: 1. Epiphysitis of infants; 2. Symmetrical effusions, usually from 8 to 15 years of age, these 2 forms being essentially associated with the congenital disease; 3. Osteitis (*a*) with simple effusion; (*b*) with gummatous infiltration of the synovial membrane and effusion; 4. Primary gummatous synovitis; these forms being met with in either the inherited or acquired disease.

[While **oculomotor palsy** is not a rare manifestation of the tertiary stage of syphilis in the acquired form of the disease, an extensive search of the literature shows that very few instances of isolated palsy of the ocular muscles have been described in connection with the inherited disease.] An

[5] Jour. Am. Med. Assoc., Oct. 12, 1895. [6] Brit. Med. Jour., May, 1896.

instructive case of the kind has been recorded by Zappert.[1] A girl of 5 years, after a few days of malaise, headache, and vomiting, manifested a paralysis of the muscles supplied by the left oculomotor nerve, with iridoplegia. There were no stigmata of syphilis and no visceral lesions, but the mother had suffered from syphilis before the child's birth. Complete cure followed after 3 months of specific treatment. The author believes the lesion to have been a peripheral neuritis.

Coutts[2] in his Hunterian Lectures reviews the question of the **transmission of syphilis,** drawing attention to the remarkable persistence of the power of syphilitic infection transmitted by father to child. Maternal syphilis he finds is more injurious to the infant than is paternal. He believes that inherited syphilis is occasionally contagious, but that the virulence of such contagion has been grossly overestimated. He suggests as a reason for this infrequency of infection that the disease dates from conception, and not from birth, and at the age at which symptoms appear the disease is generally of about a year's standing, and may have lost some of its pristine virulence during both uterine and extrauterine existence. He also suggests that some product absorbed by the mother in her first pregnancy may influence the succeeding conceptions and largely modify the disease and its power of contagion in the infants resulting from these conceptions. In marked contrast with the rarity of infection from inherited syphilis is its frequency from the acquired form in infants.

Glandular Fever.—Soca[3] records a case of glandular fever in a boy of 11 years in whom on the 13th day acute nephritis developed. Albumin continued to be found in the urine for more than 2 months. In general symptoms the case was almost identical with those described by Pfeiffer and Von Stark, but differed from them in the occurrence of nephritis, which followed the course of a typical scarlatinal inflammation. A second case, which resembled closely that reported by Comby a few months before,[4] presented a slight albuminuria from the beginning, lasting 6 days, or 2 days longer than the febrile period of the disease. [If we can accept the accuracy of this observation, we must conclude with the author that glandular fever is not always a malady of slight importance. Further observations of the kidney-condition in this affection will be awaited with interest.]

Erysipelas.—Successful employment of antistreptococcic serum has been made by Steele in a case of extensive erysipelas in an infant 3 weeks old.[5] No other treatment was adopted, beneficial results being observed soon after the first of the 3 injections made.

GENERAL NONINFECTIOUS DISEASES.

Rachitis.—In the **etiology** of rickets Garrod and Fletcher[6] direct attention to what may be termed the maternal factors in the causation of this

[1] Arch. f. Kinderh., Bd. xix. S. 161.
[2] Lancet, Apr. 11, 18, 25, 1896.
[3] La Méd. infant., Sept. 15, 1895.

[5] Brit. Med. Jour., Dec. 7, 1895.
[6] Ibid., Sept. 21, 1895.

disease, and thus emphasize very opportunely the fact that there are other causes at work besides bad hygienic surroundings and improper food. Under the head of antepartum causes they group—1. Ill-health, malnutrition, or disease of the mother during pregnancy; 2. Want of fresh air and exercise during pregnancy; 3. Numerous and rapid pregnancies; 4. Multiple pregnancy; 5. Advanced age of mother at birth of child; 6. Lactation during pregnancy; 7. Heredity; 8. Syphilis. Illustrative cases are quoted. As postpartum causes they enumerate—1. Deficiency of milk-supply due to (*a*) abnormalities of mother—*e. g.* retracted nipples; single available breast, owing to abscess, new growth, etc.; (*b*) abnormalities of child—*e. g.* hare-lip, cleft palate, etc.; (*c*) sharing of supply by twins; (*d*) deficient activity of gland. 2. Deficient quality of milk-supply due to (*a*) mother's ill health during lactation; (*b*) menstruation during lactation; (*c*) pregnancy during lactation. 3. Excessive duration of lactation. Almost all the cases quoted were in children fed upon the breast at the time of development of the disease or until within a short time before—an observation which goes to show that in England, at least, rachitis in breast-fed children is not a rarity.

Of considerable interest in this connection is the experimental study by Rey[1] upon the **absorption and elimination of lime-salts.** This subject was investigated some years ago by Rudel, who concluded that the absorption of lime-salts from the intestine was accomplished in the same way in both rachitic and nonrachitic subjects, and that rachitis should not be attributed to an insufficient absorption of the lime-salts of the food. Rey's researches confirm Rudel's earlier conclusions. A comparative study of the influence of phosphorated cod-liver oil, the plain oil, and phosphorus alone upon the absorption and elimination of lime-salts in rachitics showed that the phosphorated oil decidedly increases both absorption and elimination, even more notably than does the plain oil. On the other hand, phosphorus alone seemed to exercise no influence upon either process.

Thompson[2] records a case of **tetany** associated with laryngospasm in a rachitic child aged 15 months, in which the thyroid extract was not only ineffectual, but seemed to aggravate the condition. In the light of the very encouraging results obtained by Bramwell[3] from thyroid extract in a similar case, it is evident that we still lack much important knowledge of the physiologic activity of the thyroid secretion and of the nature and pathology of tetany, which doubtless will be elucidated in the near future. Sterling's[4] study on rickets, which is especially valuable for the extensive bibliographical list accompanying it, deserves mention among the notable papers of the year.

A further contribution to the discussion on the integrity of the **sense of taste** in rachitic children [see *Year-Book* for 1896, p. 560] is made by Neumann.[5] Using quinin as the test, this observer found that in 36 normal children 7 (19%) had no taste-perception, while 14 gave moderate and 15 strong

[1] Deutsch. med. Woch., No. 35, 1895.

[4] Arch. f. Kinderh., Bd. xx. S. 1.
[5] Jahrb. f. Kinderh., Bd. xli. S. 155.

response. Among 93 children with moderate or marked rachitis, 27 (29%) were without taste, 30 gave moderate and 36 strong response. Or, by separating cases with laryngismus or a more general spasmodic condition, 48 children remain, giving in 9 cases (17%) no reaction, in 19 a moderate and in 20 a strong response. Of the 44 rachitics showing spasmodic symptoms, taste-reaction was wanting in 17 (39%). It is thus seen that taste-perception is wanting in rachitic children no more frequently than in the nonrachitic, excepting only among those suffering from convulsive conditions, in whom such defect is more frequent.

Scurvy.—Little that is new has appeared upon this interesting disease since our last review. Cases have been reported from various parts of the United States, notably those of Snow,[1] Love,[2] Merriman,[3] Miller,[4] Machell,[5] Garber,[6] and Cheney.[7] Morse[8] reports 2 cases, 1 of which bears out Starr's[9] contention, as noted last year, that prolonged sterilization is capable of producing scurvy even where the quality and proportions of the ingredients of the milk-mixture are all that could be desired. A case reported by Douglas[10] and 1 by Abt[11] also add corroborative testimony to this view.

[In Germany **the rachitis-theory** still holds a prominent place, though there has appeared some testimony in favor of the English and American view.] Freudenberg[12] reports a case occurring in a child of 9 months, fed upon the breast till the age of 3 months, and then upon sterilized milk. During an attack of pertussis scorbutic symptoms developed. The child was seen by Prof. Baginsky, who diagnosticated "Barlow's disease" and advised phosphorated cod-liver oil. No improvement followed in the next 15 days, and an antiscorbutic treatment was then adopted, consisting of lemon-juice to the gums and the yeast of beer internally. The symptoms of scurvy disappeared in 15 days. In consequence of the rapid cure under antiscorbutic treatment after the failure of medication addressed to a supposed rachitic condition, the author concludes that Barlow's disease is really an infantile scurvy. Four cases, 3 of which were fatal, have been reported by Meyer.[13] All 4 children were between the ages of 5 and 7 months, had been fed exclusively upon Rieth's albumose-milk, and were rachitic. [One of the fatal cases was certainly scorbutic, as the postmortem notes clearly show, but the other 2 cases are very doubtful, despite the author's ingenious argument for their admission as instances of "Barlow's disease."] The apparent deleterious effects of albumose-milk were attributed by Hamburg, who discussed the paper, to the presence of a notable quantity of potassium carbonate used in the manufacture of the preparation. This defect he stated had been already remedied by the substitution of the corresponding sodium salt.

Townsend[1] reports 12 cases of scurvy, 6 of which were seen in dispensary practice [an unusual experience, since hitherto the disease, according to general observation, has been almost exclusively encountered among the well to do]. As regards the diet, 2 had been fed on proprietary food and water without any milk; 5 on condensed milk and water (generally very much diluted), with some proprietary food added in all but 1 case; 1 on boiled milk and a proprietary food; another on sterilized milk and oatmeal water; while 3 had been fed on a mixture of cream, milk, and water with sugar of milk, sterilized at 212° in 2 cases, and pasteurized at 167° in the third. Of the last 5 cases, there were 2 in which the quality of the food, although not up to the standard, was of fair strength, and where boiling in one and steaming at 212° in the other were employed. In both cases the quality of the milk mixture was improved when the sterilization was omitted, so that a fair estimation of the influence of sterilization could not be gained.

Osteopsathyrosis.—Griffith[2] reports a case of idiopathic osteopsathyrosis, or fragilitas ossium, in a boy who had had several fractures occurring at or soon after birth, and who up to the age of 2 years had suffered in all 17 or 18 fractures from the slightest causes. His general health was good, and there was no constitutional affection in him or his parents to account for the condition. With regard to the pathology and diagnosis, the author discusses the relation of the disease to rickets, osteomalacia, and to imperfect osseous development. While he believes that the disease may and probably does bear a certain relation to these pathologic conditions, he is certain that it is not of a rickety nature, although it may sometimes be combined with this disease.

Diabetes.—An elaborate study of diabetes in childhood has been made by Wegeli,[3] based upon 108 cases collected from the literature and 28 coming under his own observation. Heredity seems to play a prominent part in etiology, and after this traumatism; 2 instances were attributed to anesthesia, 1 by chloroform, the other by nitrous oxid. In the first year of life the disease is naturally very rare, only 3 cases out of the entire number being under 1 year of age. The longest duration of the disease was 4½ years in one of the cases coming under the author's own observation. A rapidly fatal case in a boy of 3 months is recorded by Bell.[4] A paternal aunt had died of the disease. [This case and 2 collected by Wegeli, each aged 3 months—1 reported by Caron, the other by Nichues—probably mark the earliest age at which the disease has been observed.]

A case of **glycosuria** apparently **dependent upon** the presence of numerous **thread-worms** in a child of 5 years is recorded by Parry.[5] After expulsion of the worms by santonin the glycosuria disappeared and the child regained its former health.

Arthritis Deformans.—A rare example of arthritis deformans in a child 6½ years old is described by Koplik.[6] The disease had existed about 18

[6] Arch. of Ped., Mar., 1896.

months; all the joints of the extremities were affected, and pain in one joint or another was almost constantly present. Almost every known remedy had been tried without avail; the pain, the most distressing symptom, seemed most relieved by salicylic acid. The author thinks there are many points in favor of the neurotic origin of these cases, as was suggested by Charcot, from the symmetric affection of the joints, the atrophy of muscle and skin, and the absence of syphilis or tuberculosis in the child or in its ancestors, and finally the absence of cardiac lesion and rheumatic history. If only those cases that correspond with the Charcot-Weil description and portrait be taken into account, there are only about 18 cases of this interesting disease recorded in the literature.

Infantile Myxedema.—Burckhart[1] reports a case of infantile myxedema in a girl of 3 years who since birth had exhibited increasing symptoms of the disease. Thyroid feeding produced marked improvement, but death occurred within 3 months from bronchopneumonia. The autopsy showed the normal tissue of the thyroid replaced by a mass of fat. Another case, first seen at the age of 6½ years by Parker,[2] has been reported, with photographs, after a year's thyroid treatment. At the time of the report she had the appearance of any healthy child from 2 to 3 years of age, but was unable to talk—with the exception of saying a very few simple words like "dad," "mam," etc.—and had several healthy permanent incisors, most of the old black stumpy milk-teeth having disappeared. In this case 5 gr. in tabloid form were given every week-day for 6 months, and the dose was then increased gradually to 10 in a week, 1 daily and an extra half on alternate days; finally, 2 every day were given. [For so young a child the dose tolerated is unusually large.] Two cases illustrating satisfactory results of treatment are recorded by Emily Lewi from Koplik's clinic,[3] and Koplik[4] gives the notes of another case which showed improvement during the short time it was under his observation.

Those interested in the subject will find a table of 40 published cases of **cretinism treated by thyroid administration** appended to a paper by Peterson and Bailey,[5] who also record 2 cases showing satisfactory results.

New Growths.—Fisk[6] reports a case of multiple large round-celled sarcoma in a child aged 6 months. The largest growth, which was situated in the interscapular region, had a circumference at the base of 17 in.; there were also masses in the right axilla, and one in the left popliteal space. Coley's erysipelas-toxin was tried, and the largest tumor began to break down rapidly, but death from septicemia occurred on the 10th day of treatment.

DISEASES OF THE DIGESTIVE ORGANS.

Congenital Teeth.—Ballantyne[7] gives the notes of 3 cases of congenital teeth. One of these, observed by Vargas of Barcelona, was an instance of an

[6] Arch. of Ped., Apr., 1896. [7] Edinb. Med. Jour., May, 1896.

extraalveolar dental sac containing an unruptured fangless tooth. It occupied a position corresponding to the left central incisor of the lower jaw. A bibliography contains the references to 66 cases recorded.

Effects of Nutrition upon the Teeth.—The influence of nutritional disturbances in infancy upon the development of the teeth is well shown in the results of Barton's[1] examinations of the teeth of 202 children. Of this number there were found 10 cases of well-marked erosion of permanent teeth, and 5 cases of erosion of the milk-teeth. The latter cases occurred in 67 hand-fed children. Of the entire number of children, 24 had been fully breast-fed, and there was no case of erosion among them; 2 cases of very early decay were associated with very bad artificial feeding. In 1 case in which there had been temporary bad feeding with a patent food in early infancy the permanent teeth showed a horizontal line marking the period at which nutrition had suffered.

Diseases of the Liver.—A case of congenital atresia of the hepatic duct, with cirrhosis of the liver, under the care of Finlayson, is reported by M'Callum.[2] Jaundice was first observed at the age of 2 weeks. Death occurred in the fourth month. As has been observed in cases of actual obliteration of the ducts, the stools, though pale, were, as a rule, yellow, and sometimes green. Even in the last days of life the stools were of a bright-yellow color. The common bile-duct and the cystic duct were pervious from the duodenum to the empty gall-bladder, but the duct from the liver was represented by a mere cord.

Edwards[3] completes the report of the case of **hepatic cirrhosis** which formed the basis of his paper on the subject published in the Archives of Pediatrics, July, 1890. Several beautiful characteristic microphotographs of the liver tissue, made by Gray, illustrate the marked increase in both interlobular and intralobular connective tissue. The author thinks that the Germans have presented evidence which makes it probable that softening in the neighborhood of the lenticular nuclei (most markedly shown in a case of cirrhosis in a boy aged 10 years, reported by Ormerod),[4] has some essential connection with the disease.

Gilbert and Fournier[5] report 7 cases of **hypertrophic cirrhosis** of the liver occurring in children or adolescents, dating back to ages varying from $5\frac{1}{2}$ years in the youngest to 17 years in the oldest of the cases described. In general characteristics the clinical phenomena in the child do not differ essentially from those belonging to the adult type—hypertrophy of liver and spleen, jaundice with its train of secondary symptoms, absence of ascites, and maintenance, for a long time, of the appetite and general health. Some special points of distinction, however, deserve mention. In 3 of the cases the hypertrophy of the spleen greatly exceeded that of the liver, so that while the latter extended only 1 or 2 fingers' breadths below the false ribs, the spleen

[1] Brit. Med. Jour., Sept. 21, 1895.
[2] Arch. of Ped., Nov., 1895.
[3] Ibid., July, 1895.

[5] Rev. mens. des Mal. de l'Enf., July, 1895.

filled the entire left flank, reaching the umbilical line and descending well into the pelvis. Such a disproportion between liver and spleen does not occur in adult cases. Another peculiarity in 3 of these cases was found in certain nutritive changes in the bones of the phalanges of fingers and toes and in the extremities of other bones—changes which have not been previously described in connection with this disease. These lesions resembled those described by Marie under the name of ostéo-arthropathie hypertrophiante pneumique, but in the most marked case the hypertrophy of liver and spleen was too slight to interfere with respiration—an important element in the etiology of Marie's disease. A third point to which attention is directed is the retardation in development exhibited by such patients, especially when the disease begins about the time of puberty.

Auché and Coyne[1] report a case of **acute yellow atrophy of the liver** in a girl of 10. At the autopsy the colon bacillus was found in the biliary vessels, though 8 hours before death an examination of the blood of the median cephalic vein gave negative cultures. The case confirms Hanot's assertion relative to the existence of a grave hypothermic icterus determined by the bacterium coli.

Diseases of the Gastrointestinal Tract.—Under the general heading of **Summer Diarrhea** the whole subject of the gastrointestinal diseases of hot weather may be considered. Numerous valuable papers have appeared during the year, most of which show the influence of the recent contributions to our knowledge of the pathology and bacteriology of these diseases. Among these may be mentioned the papers of Allyn,[2] Northbridge,[3] and Engelmann.[4] In the question of treatment the general teaching seems to be coming down to well-established principles and greater uniformity in therapeusis. Notable differences of opinion, however, still occur. A very sensible paper by Snow[5] describes the symptomatology and treatment of these cases at the Buffalo Fresh-air Mission Hospital. According to his experience, the only medicines producing positive effects are opium and subnitrate of bismuth. Intestinal antiseptics—calomel and sodium salicylate excepted—were rejected after trial. Intestinal irrigations are largely used, preferably warm. If the feces contain much mucus, borax is added to the water, and if astringents are indicated, 1 to 2% solutions of tannic acid are used. In toxemic states saturated boric-acid solution is employed in large quantities (2 to 4 quarts), being used once or twice daily. Calomel is advocated if the stomach be irritable. Fever is controlled by hydrotherapy, and stimulation by whisky is employed in nearly all cases where vomiting is not produced. Strychnin, strophanthus, and caffein are also of value, hypodermic stimulation being of great value in case of sudden cardiac depression. This epitome is fairly representative of the consensus of professional opinion. Fischer[6] strongly advocates betanaphthol bismuth in doses of 5 to 10 gr. to a child of 1 year every 2, 3, or 4 hours.

Alcohol he rarely uses, and then preferably by rectal injection in a large quantity of water. As astringents, Poole[1] uses only nitrate of silver or tannic acid in irrigating solutions; as a purgative and antifermentative, calomel.

As to the particular purgative to be employed in the early stages, there is considerable difference of opinion. In the discussion on several papers read before the Section on Diseases of Children of the American Medical Association Booker[2] stated that he relies on **calomel** in fractional doses, while Koplik[3] said he feared mercury in any form, but favored **magnesium sulphate.** This drug was strongly advocated by Patterson,[4] who reports 2 series of 25 and 55 cases treated exclusively with it. In the second series 2 died and 7 did not report after the first day. From 1 teaspoonful to a tablespoonful of the salt, according to the age, moistened sufficiently to be swallowed, was given daily until the discharges became yellow. The children were reported to be relieved of pain and restlessness, with the induction of quiet sleep. The after-treatment consisted of general tonics. Griffith[5] believes in the judicious use of **opium** after food has been stopped and the intestinal canal thoroughly cleansed. Weaver[6] also approved of the use of calomel, and thought opiates necessary. The use of **intestinal antiseptics** in infantile diarrhea is admirably discussed by Fenwick,[7] who has discarded astringents and opium. In almost every instance in his experience where these latter remedies had been previously tried without effect the substitution of an antiseptic was at once followed by complete success. "Acute dyspepsia is readily cured by dietetic treatment combined with the use of castor oil or an emetic. Antiseptics are only necessary when the disorder has already continued for several days and has resisted the simpler methods. Under these conditions calomel is of the utmost value when administered in doses of $\frac{1}{6}$ to $\frac{1}{3}$ gr. every 3 or 4 hours." In chronic diarrhea due to fermentation he believes in the use of antiseptics that exert their specific action within the stomach, where the disorder commences. In such cases he now uses **resorcin** in doses of 3 gr. every 4 hours, even for infants only a few weeks old. When the disorder has lasted for a long time and follicular ulceration of the large intestine exists, the drug may be advantageously supplemented by those remedies which exert their antiseptic properties in the intestine, and of these **benzol-naphtol and salicylate of bismuth** are to be preferred. The former is but slightly toxic, and must be given in full doses at short intervals (as high as 40 gr. in 24 hours have been given with excellent results).

Frederick Holme Wiggin[8] presents some interesting statistics of **infantile intussusception** and its treatment drawn from the study of 103 cases collected from the literature. Nearly 50% occurred during the 4th, 5th, and 6th months, in nearly equal proportions; 75.4% of the cases occurred in males, and 89% were of the ileocecal variety. Abdominal tumor was seldom absent, as was to be expected in such a large proportion of cases of the ileo-

[8] Med. Rec., Jan. 18, 1896.

cecal variety. Several of the reporters called attention to the necessity, in all suspected cases of this trouble, of making a conjoined abdominal and rectal examination, for in some instances a tumor was revealed by this means after abdominal or rectal palpation alone had failed to discover it. Thirty-nine of the cases were treated only by means of inflation or enemata, or both. Of these, 16, or 41%, recovered. The average hour after the onset when the treatment began was the 41st. Of cases in which celiotomy was performed, 64 were collected, 21 of which, or 32.8%, were successful, the average age of the infants being 6½ months. In 17 of these cases inflation or enemata, or both, had previously been tried without success. If from the total number of cases those are eliminated in which either the operation was abandoned, the bowel incised, and an artificial anus made, or resected and an anastomosis effected, there are left 45 cases, of which only 24 resulted fatally, reducing the mortality to 53.4%. If, again, only those operations are counted that have been performed since the perfected technic of abdominal surgery has become generally known—say since 1889—there results a total of 18 cases, of which 14 were successful and 4 unsuccessful, or a mortality of only 22.2%, which the author believes is a fair estimate of the risks of abdominal section to-day performed on a young infant for the relief of this disorder, if done within the first 48 hours after onset.

Ruhrah[1] has seen postmortem intussusceptions occur during an autopsy upon the body of a year-old infant 20 hours after death from endocarditis. When the belly was opened the intestines appeared normal, but 5 minutes later, while the thorax was being dissected, a portion of the ileum, 6 cm. in length, was observed to invaginate itself into the gut below. Handling of the intestines provoked a repetition of the phenomenon in no less than 20 or 30 instances. [It is stated that no solutions were used in or about the abdomen. It would be interesting to know what medication had been employed.]

In the early treatment of **perityphlitis** in childhood Schlossmann[2] holds that the intestines should be kept as quiet as possible, in the hope of arresting the inflammatory process and of aiding the formation of firm localizing adhesions. In childhood, as Matterstock and Parker have pointed out, necrosis and gangrene of the appendix occur more frequently and with greater rapidity than in adults: for this reason the author advises that purgatives and enemata should be prohibited. He quotes a case recorded by Schäfer[3] in which perforation of the appendix and secondary rupture of the abscess into the abdominal cavity were justly attributed to purgatives and enemata given prior to admission to the hospital. Opium, he thinks, is indicated. It should be given in doses approaching the toxic limit, under careful observation. In such conditions the drug is well tolerated, and, according to the author's research, there is no record of a case of perityphlitis in which alarming symptoms have been produced by opium. In view of the rapid course run by perityphlitis in childhood the author is inclined to early operation.

[3] Deutsch. med. Woch., No. 14, 1895.

Pseudomembranous enteritis is so unusual in early life that Snow's case,[1] in a girl of $2\frac{1}{2}$ years, deserves mention. After a severe attack of whooping cough she developed ileocolitis, which lasted 6 weeks. In the most acute stage of the diarrhea she began to pass pieces of membrane and tubular casts of the bowel; 6 weeks later, the membranes being daily in the feces, several round-worms were evacuated, after which no more membrane appeared in the stools for $4\frac{1}{2}$ months, when, coincident with an attack of grippe-bronchitis, bits of membrane and 2 ascarides were passed for 2 days. Contrary to the usual experience in adult cases, the passage of the casts was not accompanied by pain or tenesmus, and caused no more discomfort than the passage of a normal stool. The association with lumbricoids was regarded as accidental.

Intestinal Parasites.—Mitra[2] has seen a case of fatal exhausting diarrhea in a child 10 years of age, apparently dependent upon the presence of a large number of round-worms in the intestine. During the 8 days the child was under treatment 111 worms were passed.

Congenital Hypertrophy of the Colon.—Three new cases of congenital hypertrophy of the colon are recorded by Berti.[3] In all the descending colon deviated to the right and terminated in a sigmoid flexure which ascended along the vertebral column, and then descended, this unusual course being permitted by a long and very movable mesocolon. These cases, with those reported by Mya in 1894 [see *Year-Book* for 1896], bring the total of cases hitherto reported up to 12.

THE BLOOD AND CIRCULATORY SYSTEM.

Cardiac Anomalies.—Several cases of cardiac anomaly have been recorded, notably those of Acker[4] and of Holt;[5] similar cases were briefly referred to in discussion by Packard and McDonald.[6] In Holt's case, in a female child 9 months old cyanotic from birth, the aorta was $\frac{5}{8}$ in. in diameter, and arose from both ventricles, the origin being directly over the ventricular septum, but more from the right than from the left ventricle. The pulmonary artery was about one-fourth the size of the aorta. The pulmonary opening admitted only a very fine probe; this was so small that probably no blood passed through it during life. The ductus arteriosus was open, the diameter being about $\frac{1}{12}$ in. The right ventricle was much larger than the left and its walls were twice as thick. The ventricular septum was deficient at its upper portion, the opening being $\frac{1}{2}$ in. in diameter. The right auricle was much enlarged, the left auricle small. The pulmonary veins were very small. The foramen ovale was closed and the auricular septum normal. The systemic circulation was carried on chiefly by the right ventricle, as only a very small amount of blood could reach the lungs through the pulmonary artery by way of the ductus arteriosus. The chief supply to the lungs was probably through the bronchial arteries.

In another case, seen by Railton,[1] in a child of 4 years, dead of bronchopneumonia, the tricuspid valve was the seat of large verrucose vegetations covered with a deposit of fibrin. Close to the tricuspid orifice were a few other vegetations on the auricular edge, and one recent irregular ulcer. The remaining orifices and valves were normal, and the ductus arteriosus and foramen ovale were closed. There was a deficiency of the septum of the ventricles about the undefended space large enough to admit a quill. This opening was larger at the side of the left ventricle than on the right side, where it ended between the insertion of two cusps of the tricuspid valve nearer to the right auricle than to the ventricle. The edges of this orifice were quite smooth. It was evident that the lesion of the tricuspid valve had started during fetal life, and it seemed almost equally clear that the endocarditis had also continued its evolution subsequently to birth. Railton is inclined to believe the defect in the septum to be the cause of the endocarditis.

The Cardiac Hypertrophy of Growth.—The present status of the so-called "cardiac hypertrophy of growth," which was first described by Blache in his thesis (Paris, 1869), and later most valiantly championed by Germain Sée, is very satisfactorily sketched by Romme.[2] He quotes the recent critical studies of Huchard,[3] Potain and Vaquez,[4] and Springer,[5] all of which arrived at the conclusion that the cardiac hypertrophy of growth does not exist, and that when a hypertrophy is observed during adolescence the cause must be sought in some more definite and pathological condition. To this opinion the author most heartily subscribes.

DISEASES OF THE RESPIRATORY SYSTEM.

Nasal Catarrh.—Bermann[6] urges the necessity of paying attention to the slight nasal catarrhs occurring in young infants, since these repeated congestions cause permanent derangement of the mucous membrane and deflexion of the nasal septum. For this purpose he applies carefully to the nasal passages a camel's-hair brush wet with a 2% solution of silver nitrate, and instructs the nurse or mother to make such an application whenever the child is noticed to make any noise in breathing through its nose. For chronic nasal catarrh associated with mucous hypertrophies or polypoid degeneration he strongly recommends the use of trichloracetic acid. The nose is first cocainized, and the pure acid is then applied by means of a glass tube drawn out to a fine point and bent at a proper angle, being blown out of the tube on to the hypertrophied area. The tube will hold only a small fraction of a drop by capillary attraction, so that no danger of an excess of acid need be feared. The galvanocautery, he states, produces cicatricial tissue and gives rise to a dry catarrh, while the use of trichloracetic acid is followed by no sloughing, and a normal mucous membrane results. These applications should

be repeated at intervals of from 1 to 2 weeks. Even in cases of atrophic catarrh or ozena the use of this acid is said to have been followed, after sufficiently long treatment, by complete cure.

Retropharyngeal Abscess.—Hand[1] reports a case of mumps in a boy of 22 months, the subsidence of the parotid inflammation being followed by enlargement of the lymphatic glands at the angles of the jaw, by an extremely irregular fever, and by intense anemia. No cause could be assigned for the persistent temperature elevation, which followed the hectic type, until about 2 weeks after the onset of the parotitis, when the presumptive diagnosis rested between tuberculosis and retropharyngeal abscess. Physical signs of either disease, however, were wanting, but attacks of cyanosis and trouble in swallowing now began to be noticed. The pharynx, except for slight catarrh, exhibited no abnormality, and continued so for 11 days longer, when after an interval of 48 hours between visits, a fluctuating swelling was observed nearly occluding the pharynx. Incision of the abscess was followed by rapid subsidence of symptoms, convalescence being interrupted only for a day by incipient mastoiditis. [The case is noteworthy for the slow development of the abscess, since the process in children is rarely prolonged beyond a week.]

Koplik[2] contributes a valuable paper on the acute retropharyngeal abscess of infancy and childhood, based upon an experience of 77 cases. He holds that in the light of our present knowledge the term "acute idiopathic" as applied to this affection is erroneous. The anatomic investigations of Gillette have shown that the retropharyngeal space is the seat of several lymph-nodes which are intimately connected with the system of lymph-vessels of the tonsils, the soft tissues of the palate which are connected with the deep facial glands, and the deep cervical. All infectious processes invading the tonsils or soft palate or lesions of the mucosa of the mouth are liable to draw into sympathy these retropharyngeal glands. One or more of these nodes may be affected, and in the latter case the retropharyngeal swelling may be felt and seen from the inside of the mouth, and also recognized by a palpable swelling on the side of the neck. The author has succeeded in isolating 4 distinct species of streptococci, which were the only organisms present in the pus of the acute nontuberculous abscess; these he divides into 2 classes—the streptococcus brevis pharyngis (*a* and *b*) and the streptococcus longus pharyngis (*a* and *b*). Animal experiments with both varieties of streptococci failed to produce effects similar to those seen in experiments with streptococci taken from virulent pus. In no animal was tuberculosis produced from the injection of any of the pus in its pure crude state, thus showing that the contention of some observers, that the acute retropharyngeal abscess in many cases is tuberculous, is unfounded. A study of the age in this series shows that the affection is preeminently one of infancy, 65 of the 77 being under 1½ years, and 55 under 1 year of age. The author advances a forcible argument for operation by internal incision, reserving the external operation, as advised by Burkhardt, for the chronic tuberculous form, for the burrowing septic variety, and for those cases where the deep cervical

[1] Arch. of Ped., July, 1895.

[2] N. Y. Med. Jour., Apr. 4, 1896.

glands are involved. Dollinger[1] also records a case in a child of 8 months, the subject of general tuberculosis. [The fact that so large a number of cases have been observed within the short period of 6 years shows that the possibility of the presence of this affection must be constantly borne in mind.]

In this connection attention should be directed to an important monograph upon this subject by Damm.[2] It is based upon the extensive hospital service of the author, and is supplemented by histories of cases furnished by Edmund Owen of London and Henry Ashby of Manchester. A complete bibliography dating back to 1820 is appended.

Nondiphtheric Membranous Angina.—Comby[3] calls attention to the not infrequent occurrence of pseudomembranous inflammations of the mucous membrane of the tonsils, nose, pharynx, or even larynx, of infants and young children—appearances which are too readily accepted by the physician as diphtheric, and for which the most rigorous specific treatment is at once adopted, with all the anxieties and hardships to the family incident to a declared case of diphtheria. The author points out that in many of these cases bacteriologic cultures show the presence of streptococci or staphylococci and the absence of the Klebs-Löffler bacillus. The statistics which have lately been gathered in connection with the serum-treatment of diphtheria have shown that in many hospitals as high as 25% of the cases applying for treatment are proved by culture-tests to be spurious cases. [While the course of these cases, when primary, is sometimes attended with severe constitutional symptoms, the outcome is very usually favorable, provided the patient be spared the heroic local and constitutional treatment so frequently instituted for diphtheria.]

Enlarged Bronchial Glands.—West[4] reports 2 cases of enlargement of bronchial glands occurring in brother and sister, in which creasote effected a relief from all symptoms. Whether this fact is to be taken as an indication of a tuberculous condition is left an open question by the author.

Pneumonia.—Claude[5] records a fatal case of croupous pneumonia in a delicate child of 2 years in which the autopsy revealed phlebitis of the cerebral veins, with thrombosis of the dural sinuses, extensive extravasation of blood, and softening of the brain-substance. Cultures from the extravasations and softened substance produced colonies of the staphylococcus albus, but those made from the thrombi showed characteristic colonies of the diplococcus pneumoniæ. Although the pneumococcus has been established as a frequent cause of meningitis, the author believes this to be the first recorded instance of cerebral phlebitis caused by this organism. In other cases the bacterium coli commune or streptococci have been found.

An interesting glance at the **treatment of pneumonia** at six of the largest children's hospitals in the United States is afforded by a series of short

[2] Bidrag til Laeren om den Akute, Saakaldte Idiopatiske Retro-pharyngeal Absces hos Born. Kjobenhavn, Ernst Bojesen, Olsen & Co., 1896. [3] La Méd. infant., Aug. 15, 1895.

[4] Arch. of Ped., May, 1896. [5] Rev. mens. des Mal. de l'Enf., July, 1895.

papers[1] contributed by members of their medical staffs. These institutions are the St. Mary's Free Hospital for Children, New York, the Babies' Hospital, New York, the Children's Hospitals of Philadelphia, Boston, and Washington, and the New York Foundling Hospital, the reporters being, respectively, Swift, Holt, Griffith, Buckingham, Adams, and Northrup. After careful comparison, the practice in all these institutions is found to be much the same. Swift and Holt, more than the others, insist upon the maintenance of a temperature of 70° to 75° F. in the ward, and advocate steam inhalations, with vaporization of creasote, pine-needle oil, turpentine, or benzoin. In view of recent writings against the use of alcohol in acute disease in children, it will be noted with interest that this drug is largely employed in all these representative institutions. The poultice is passing out of use, except occasionally for pain or dyspnea; the cotton jacket has been altogether discarded by some of the writers; and expectorants as a routine are less and less used. Counter-irritation, however, especially in the lobular form of the disease, is universally employed. Preference seems to be given to hydrotherapic measures to control excessive temperature, and antipyretic drugs are but exceptionally given. Apart from alcohol, other drugs used as stimulants are strychnin, digitalis, and carbonate of ammonium, named in the order of frequency. The value of nitroglycerin as a powerful cardiac stimulant is especially mentioned by most of these observers.

Empyema.—Koplik[2] shows that in the empyemas of childhood there are bacteriologically 4 main groups of cases: Those in which are found—1. The diplococcus pneumoniæ, fully 53.6% (Netter) to 60% (Koplik) of the entire number; 2. The staphylococcus pyogenes; 3. A streptococcus which may be of a benign or virulent variety; and 4. The tubercle-bacillus; but the literature from time to time records cases in which the Eberth bacillus and the bacillus coli communis are the causative agents, yet so infrequently as not yet to have permitted a formulation of our knowledge of these cases. If to the pure metapneumonic cases is added a distinct percentage of doubtful pleurisies, which in Netter's table are credited to the streptococcus or staphylococcus or to a mixture of these two, the empyemas in children which are nontubercular reach a proportion of fully 75%. This is in marked distinction to the conditions found in adults, according to the statistics of Netter, and more recently of Eichhorst,[3] which place the frequency of tuberculous pleurisies among adults at from 68.5 to 65.2%. Other aspects of empyema in children, as regards diagnosis and treatment, are well discussed in papers by Caillé and Winters.[4]

Edmund Cautley[5] of London publishes deductions in regard to the treatment of this interesting condition founded upon the records of 86 cases under 12 years of age, most of which were treated in St. Bartholomew's Hospital from 1883 to 1893. Of these cases no less than 84 were instances of uni-

[1] Arch. of Ped., Apr., 1896.

lateral effusion. It is in cases left entirely to nature that the characteristic sequelæ and deformities are most commonly found. The same results occasionally follow in cases treated on approved methods, but of long continuance before reaching the surgeon's hands. Small purulent effusions, he believes, are sometimes absorbed, but such a result is very uncertain, and the risk incurred by a policy of nonintervention far outweighs the risk of surgical interference. Absorption after aspiration is more probable when pneumococci only are present then when streptococci are found. If one aspiration does not result in cure, he is strongly opposed to repeating the operation. The assertion that the chances of perfect cure are better under treatment by resection, he thinks, is not supported by clinical experience, since in the series it is found that of the patients thus treated more were discharged with a sinus than was the case in those treated by incision. The interval of time during which the sinus is kept open depends upon the length of time the tube is kept in position. Early contraction of the side is more likely to follow resection than incision. The indications for resection, he states, are as follows: 1. When the ribs are so close together that it is impossible to drain the cavity without it—a condition that rarely occurs in children and only likely to be found in long-standing cases; 2. When subsequently to the simpler operation drainage is found to be imperfect, the indications consisting in a high temperature and an offensive discharge; 3. When the lung has reexpanded and the chest-walls contracted, and yet the sinus does not close; resection of portions of several ribs is generally required in such cases. In cases of double empyema the best treatment, according to the author's conclusions, is simple incision and drainage, allowing an interval of a few days to elapse between the two operations. More particularly in cases of double general effusion he thinks it better to aspirate first on both sides in order to diminish the quantity of fluid and relieve the heart. Next day operation should be made on one side, and a few days to a week later upon the other side. The left side should be chosen for the first operation, and local rather than general anesthesia employed. In cases of general effusion on one side and localized effusion on the other evacuation of the general effusion should be first done, and the operation repeated on the other side a few days later. Finally, in cases of double localized effusion simultaneous drainage may be adopted, but it is a wise precaution to wait a few days between the two operations.

DISEASES OF THE NERVOUS SYSTEM.

Hydrocephalus.—As a means of diagnosis between intraventricular and extraventricular effusions, d'Astros[1] suggests the propriety of exploratory puncture. In ventricular hydrocephalus the small proportion of albumin and the abundance of sodium chloride found in the exudate furnish a ready means of distinguishing the cerebrospinal fluid from that found in the extraventricular effusion. While surgical intervention in internal hydrocephalus offers little hope of amelioration, he believes that the encysted condition of an

[1] La Méd. infant., Nov. 15, 1895.

external effusion and its comparative isolation from the nerve-centers justify further efforts to relieve such conditions by surgical means.

A remarkable case of fetal hydrocephalus, an illustration of which is presented (Fig. 128), has been recorded by Alexander Fulton[1] of Philadelphia. The mother was a healthy tertipara, 28 years old, 5 feet $2\frac{1}{2}$ in. in height, weighing 90 lb. The fetal head contained about 2 quarts and a pint of serum, weighing 8 lb., and measured 23 in. in the fronto-occipital circumference.

FIG. 128.—A case of fetal hydrocephalus (Univ. Med. Mag., Dec., 1895).

Meningitis.—For purposes of diagnosis Quincke's operation of puncturing the vertebral canal has given some encouraging results. Fürbringer[2] reported to the Medical Society of Berlin that he had practised this puncture more than 100 times upon 86 patients. The 2d, 3d, or 4th intervertebral space in the lumbar spine was chosen, the patient sitting up rather than reclining, general anesthesia not being necessary. With new-born infants the needle should penetrate about 1 cm., and with older children the depth should be increased, approaching 7 cm., which is the depth necessary in the robust adult. The amount of fluid withdrawn may reach 110 c.c.; 37 of the cases examined had tuberculous meningitis; in 30 of these the liquid withdrawn contained the tubercle-bacillus, thus verifying the diagnosis in 80% of the cases, among which several presented insufficient clinical symptoms to warrant a definite diagnosis. In 3 cases of serous meningitis the therapeutic results were transient. In another case creamy pus was withdrawn, permitting the establishment of a diagnosis of cerebrospinal meningitis, as was subsequently verified by autopsy. In another case with symptoms of myelitis and pneumonia the pneumococcus was found in the greenish-colored liquid withdrawn. A. Fränkel[3] agreed with Fürbringer that the operation was harmless if properly done. The puncture should be made about on the plane of the junction of the superior and middle third of a spinous process,

[1] Univ. Med. Mag., Dec., 1895.

[2] Rev. mens. des Mal. de l'Enf., June, 1895.

[3] Ibid.

about 2 fingers' breadth from the median line. After passing through the skin the needle should be directed a little upward and inward. Heubner[1] prefers the lumbar puncture to tapping of the ventricles in chronic hydrocephalus. Rotch and Wentworth,[2] however, saw very alarming symptoms after puncture in a child 2 years old with marked cerebral symptoms attending double seropurulent otitis media. Only 6 c.c. of a clear fluid were withdrawn, but immediately after the operation the child became restless, the pulse rose to 250 a minute, respiration was superficial, and the skin cool and slightly livid. The child subsequently recovered, and no information was obtained from analysis of the spinal fluid.

Lazard,[3] who made the puncture in a case of tuberculous meningitis in a child of 13 months, succeeded thereby in checking the convulsions and bringing about a peaceful termination 24 hours later. Caillé[4] has had an experience of 4 cases. In the first 2, in children 3 and 5 years old suffering from tuberculous meningitis, bacilli were found sparingly in the flaky sediment of the cerebrospinal fluid. Wolfstein[5] also records a case in which by puncture he demonstrated the presence of staphylococci, streptococci, and pneumococci, and the absence of tubercle-bacilli. An extensive purulent meningitis without tubercle was found at the autopsy. He agrees with other observers as to the value of the method in diagnosis.

Syphilis of Nerve-centers.—Bézy[6] records the case of an infant 2 months old with a brachial diplegia of several days' duration. The father had contracted syphilis after his marriage. There was no evidence of the pseudoparalysis of Parrot. Cure resulted under antisyphilitic treatment. The lesion, according to the author, was not in the anterior portion of the vertebral column, because of the absolute integrity of the lower limbs, but affected the nerve-centers. The case should be classed, he thinks, with those recorded by Blocq[7] and by Vicarelli.[8]

Chorea.—After a study of 35 cases of chorea, the subsequent histories of which could be followed, Meyer[9] concludes that all cases of chorea minor in children are of rheumatic origin, and that where other causes seem to be active they merely play a predisposing or exciting role. In fully 80% of his observations the rheumatic character of the chorea was shown (*a*) by its sometimes appearing as an equivalent for a polyarthritic attack or after an articular explosion taking the place of a relapse; (*b*) by the contemporaneous appearance of other rheumatic manifestations in endocardium or joints; (*c*) by the fact that, in the predisposed, chorea can bring about the sequelæ of rheumatic lesions; (*d*) by the fact that in times of epidemic prevalence of articular rheumatism chorea also is much more commonly observed; and (*e*), finally,

that chorea yields to antirheumatic treatment. In the remaining 20% of cases, while no direct evidence of rheumatism could be adduced, yet no contradictory evidence was to be found, and in symptoms and course no distinction from the positively rheumatic cases could be observed.

After a review of the very meagre literature bearing upon the so-called **"congenital chorea,"** Johnston[1] concludes that the existence of a true congenital chorea is extremely doubtful, or has, at all events, not yet been established. All of the few cases reported which could be seriously considered seemed, in the author's opinion, to be examples of double athetosis due either to developmental defect or to meningeal hemorrhage injuring and irritating the motor cortex. The same subject is considered in Vignaud Dupuy's recent thesis.[2] While many of the recorded cases are rejected as doubtful or spurious, 6 cases from the literature, with 1 of his own, enable the author to draw the usually accepted conclusions in regard to this condition.

Anterior Poliomyelitis.—Trevelyan[3] gives a histologic study of a case of infantile paralysis dying from independent causes 11 months after the onset of the disease. The case thus occupies a middle position between cases of very recent origin and the old cases, in which the changes are so advanced as almost to preclude an opinion as to the starting-point of the disease. The changes here noted seemed to be entirely in favor of the disease being primary in the neuroglia including the arteries. On the other hand, there was no definite localization of the disease to any one or more groups of ganglion-cells. The overgrowth in the neuroglia, including the spider cells, was very striking, this being probably due to the irritation of the poisonous products (toxins) escaping from the blood, the infective theory apparently offering the best explanation of the etiology of the disease. Changes have been found in the neuroglia in quite recent cases, so that the irritation theory would appear best to account for the changes in the neuroglia, certainly in the earliest cases. It is interesting to observe that in this case, as in others previously examined, microorganisms have not been found in the cord. Yet the possibility of occurrence of epidemics of infantile paralysis as recorded by Medin,[4] and the experimental evidence as given by Roger,[5] and more recently by Thoinet and Masselin,[6] strongly support the view that the disease is infectious. It is most probable that it is the poisons excreted by the microorganisms that set up the disease, and this accounts for the early vascular phenomena found in the cord.

Spinal Sclerosis.—Moncorvo[7] reports 3 cases of sclerosis *en plaques* in children who bore the marks of hereditary syphilis, to prove the truth of his contention that the latter disease is capable of giving rise to the cord-lesion. This view was advocated in a paper in the same journal,[8] but seems to have met with little acceptation. Pierre Marie in his Leçons sur les Maladies de la Moelle states that there is not a single infectious disease which may not cause

[8] June, 1887.

sclerosis *en plaques*, but he adds that syphilis plays no role in the etiology of such cases. Moncorvo remarks, with justice, it seems, that syphilis at the present day deserves to be ranked as an infectious disease, and calls attention to the fact that Marie in the same work attributes to syphilis a predominant role in the etiology of tabes, which, according to Baginsky, approaches histologically more nearly to sclerosis *en plaques* than to a secondary sclerosis.

Multiple Neuritis.—Hammond[1] gives the histories of 10 cases of multiple neuritis occurring among children in the city of Bridgeport, Conn., within a period between Dec., 1894, and Oct., 1895. The ages of the children varied from 4½ months to 4½ years. In 3 cases both arms and both legs were paralyzed; in 2 cases both legs and the right arm were affected; in 4 cases only the legs were implicated; and in 1 case the intercostal muscles were the primary seat of paralysis; 2 of the cases presented typical symptoms of meningitis—1, aged 20 months, recovering; the other, an infant of 4½ months, dying after a lapse of 1 month, but, unfortunately, it was not subjected to postmortem examination. The succession of cases within a limited geographic area and their great similarity point to a common cause of origin, but no light was gained from an examination of the blood. Such a series of cases as are here reported is almost unique. The second case, in a little daughter of a physician, occurred in a house about 100 yards from that in which the first case developed; 6 other cases occurred in the practice of one physician of the city, and another in the practice of the father of the child designated above as the second case. [While by no means conclusive, the coincidences suggest the possibility of the communication of the contagion through the series of cases. This point, however, is not raised in Hammond's paper, but is a natural conclusion from a study of the cases which he here records.]

Raynaud's Disease.—That Raynaud's disease is not unusual at an early age is proved by the researches of Mangue,[2] who has gleaned from the literature, between the years 1880 and 1885, 171 cases in which the age was given. Of these 6 were under 2 years of age and 5 in the 5th year. To these the author adds 3 cases in infants in their first year and 3 in the second. This proportion of cases by the year is not equalled in the series at any age, except in the period from 30 to 43 years.

Krisowski[3] records a case of superficial gangrene of symmetric areas of the external ears in a boy of 3 years with a history of hereditary syphilis. Complete recovery took place under the administration of antisyphilitic treatment. The author discusses the relation of such conditions to cases of Raynaud's disease, properly so called, and concludes that all cases of spontaneous gangrene should be classed as Raynaud's disease, which he regards rather as a symptom-complex than a disease sui generis. [It must be remembered, however, that Raynaud in his original thesis (Paris, 1862) and in subsequent writings was careful to exclude from consideration all cases of local death dependent upon embolism, thrombosis, or changes of an inflammatory character

[1] Med. Rec., Nov. 9, 1895.

[2] Thèse de Paris, 1895.

[3] Jahrb. f. Kinderh., Bd. xl. S. 57.

in the intima of the blood-vessels, though some of the cases collected in Raynaud's original thesis do not properly come within this definition. There are on record, however, a sufficient number of cases—many, indeed, among children—wherein the clinical picture described by Raynaud is clearly reproduced; and until future pathologic studies prove that all such cases now ascribed to vaso-motor spasm are really dependent upon changes in the intima of the blood-vessels, we should reserve for this interesting nosologic division those cases which present the characteristics of Raynaud's description, and should exclude a case clearly dependent upon a syphilitic endarteritis, such as Krisowski's undoubtedly was.]

Hysteria.—Wood[1] records the case of a girl of 10, who, during convalescence from typhoid fever when 7 years old, began to vomit after taking food, and had continued so to do at intervals. Food would be retained for about 8 minutes; the face assumed a pained expression during its retention, and then everything swallowed was vomited in one gulp. Passage of the esophageal bougie produced temporary cessation of the vomiting, and under moral treatment and regimen, with removal from her family, considerable improvement occurred and the vomiting ceased, but she still had difficulty in eating in the presence of strangers. A peculiar symptom of later development was a cough which came on at night after going to bed. A large amount of frothy mucus would collect in the pharynx, causing noisy breathing, relieved only temporarily by a loud cough. This would be kept up for hours nearly every night.

DISEASES OF THE GENITO-URINARY SYSTEM.

Retention of Urine.—As a rare cause of retention of urine in infants Knöpfelmacher[2] instances a case in a female of 9 months, where the cause was found to be a sarcoma springing from the periosteum of the sacral vertebræ and compressing the rectum and neck of the bladder. The possibility of tumor of the adjacent sexual organs, especially in female children, should always be borne in mind in the event of a persistent retention.

Enuresis.—Williams[3] concludes that nocturnal incontinence is to be regarded as a symptom, varying in degree from a simple indication of the naughtiness of a wilful child to the precursory warning of subsequent nervous deficiency, and the treatment of the condition requires careful study into the causation of each particular case. No case should be lightly dismissed as of trivial importance until such careful investigation has been made. When tonic treatment is indicated, he regards potassium iodid as an extremely valuable remedy. Personally, he has seen no benefit from raising the foot of the bed. In the treatment of nocturnal enuresis Macalister[4] uses atropin, in increasing doses up to the limit of tolerance, associated with strychnin. The formula employed for children of 14 years is the following: Neutral solution of atropin sulphat, 2%, 5.60 g.; solution of strychnin chlorhydrate, 1%, 0.25 g.; syrup of bitter-almond peel, 25 g.—M. Sig. 5 to 60 drops in a little water at bedtime,

"These 'Notes' will be found very useful to practitioners who take an interest in the many newer remedies of the present day."—*Edinburgh Medical Journal.*

SECOND EDITION,
REVISED AND GREATLY ENLARGED.

Notes on the Newer Remedies

THEIR

THERAPEUTIC APPLICATIONS AND MODES OF ADMINISTRATION.

BY

DAVID CERNA, M.D., PH.D.,

Demonstrator of and Lecturer on Experimental Therapeutics in the University of Pennsylvania.

FORMING A SMALL OCTAVO VOLUME OF ABOUT 250 PAGES (7 x 5) INCHES.

PRICE, - $1.25.

The work takes up in alphabetical order all the Newer Remedies, giving their physical properties, solubility, therapeutic applications, administration, and chemical formula.

In this way it forms a very valuable addition to the various works on Therapeutics now in existence.

Chemists are so multiplying compounds that if each compound is to be thoroughly studied, investigations must be carried far enough to determine the practical importance of the new agents.

Sent post-paid on receipt of price.

W. B. SAUNDERS, Publisher,
925 Walnut Street, Philadelphia, Pa.

"The volume is a useful one, and should have a large distribution."—*Journal of the American Medical Association.*

Southern California Practitioner:

"Of its kind, the book has no equal. Its points of superiority may be enumerated as follows: Convenient size; diseases in alphabetical order, with blanks for additions at end of each letter; prescriptions and formulæ taken from the latest standard works, *and containing the latest remedies.* In the appendix the diet-table cannot but be of service to those who use the book."

Indiana Medical Journal:

"The Formulæ are all first-class, and the book is gotten up in a style that is unexceptional. It is neatly bound and indexed with the 'Imperial Index,' the best devised for reference and neatness. We heartily commend it to all who need such a companion."

Virginia Medical Monthly:

"This 'Formulary' is arranged alphabetically as to diseases, under which headings 1734 appropriate prescriptions—well selected and carefully corrected—are given. The 'Appendix' contains many items of useful information, and will be found useful to the general practitioner as a ready reference reminder."

Medical Brief:

"In compiling this work the author has introduced most of the recently-discovered drugs in the prescriptions given, his ability in selecting those contained in this work shows him to be a man of rare judgment."

New York Medical Record:

"This little book, that can be conveniently carried in the pocket, contains an immense amount of material. It is very useful, and as the name of the author of each prescription is given, is unusually reliable."

NOW READY.

SAUNDERS'

POCKET

Medical Formulary.

BY

WILLIAM M. POWELL, M.D.,

Attending Physician to the Mercer House for Invalid Women, at Atlantic City.

CONTAINING

1750 Formulæ,

Selected from several hundreds of the best-known authorities.

Forming a Handsome and Convenient Pocket Companion of nearly 300 printed pages, with blank leaves for additions.

THIRD EDITION.

Revised and Greatly Enlarged.

Handsomely bound in Morocco, with side index, wallet and flap.

Price, $1.75 Net.

Therapeutic Gazette:

"The prescriptions have been taken from the writings or practice of Physicians whose experience qualifies them to be worthy of trial. We heartily recommend this volume to all who desire to purchase such a work."

College and Clinical Record:

"The best collection of Formulæ issued for a long time, being practical, modern, and aptly chosen."

Southern Practitioner:

"An excellent pocket companion, containing the most satisfactory and rational formulæ used by the leading medical men of Europe and America, introducing in the many prescriptions contained therein a considerable number of the more important recently-discovered drugs."

American Gynæcological Journal:

"The prescriptions are of great value to the physician, by giving him the latest treatment and combination of drugs to be employed in a given case, and enabling him to study the methods of combination in use by other practitioners."

American Practitioner and News:

"Cannot but be of service to the practitioner who desires to know what is going on in the therapeutic world. The formulæ are well selected, and embrace about everything prescribed and prescribable in the Materia Medica."

Prescription:

"A valuable little volume for the office-table; a considerable library would have to be hunted through to gather the information contained under this cover."

commencing with 5 drops and increasing 5 drops every 4 days till the dose of 30 drops is reached. If at the end of a week incontinence does not cease, the dose is increased 5 drops every 4 days until 60 drops is reached; then the number of drops is decreased 10 every 4 days till the treatment is finished.

Phimosis.—That many puzzling reflex symptoms may be due to phimosis is a well-known fact. That this condition may be associated with, and apparently be the cause of, severe cerebral symptoms is illustrated by a case recorded by King:[1] A delicate male child of 6 months, offspring of a delicate mother and a father who died of tuberculosis before its birth, was taken ill, after several days of irritability, with fever, frequent liquid stools, hot head, nape of neck sensitive to pressure, opisthotonos, head rolling, mouth hanging open and tongue protruding, cephalic cry, bulging fontanel, retracted abdomen, scanty, infrequent urine, and other symptoms which warranted three physicians who saw the case in making a diagnosis of meningitis. Phimosis with pinhole orifice was found, and after 24 hours, when all the symptoms had become aggravated, circumcision was performed. Within a few hours the fever vanished, the urine became abundant, and all the other alarming symptoms disappeared. [It seems likely that the renal insufficiency in this case played a large part in the causation of the alarming symptoms.]

Vulvovaginitis.—Marx[2] calls attention to the dangers of gonorrheal vulvovaginitis in children. As in the adult female, serious complications may arise, such as urethritis, cystitis, and even involvement of ureters and kidneys, while through the uterus tubes, ovaries, and even peritoneum, may be involved in the infection. In some cases by rectal exploration the author has been able to detect an effusion in the lateral culdesacs, and in several cases he believes he has detected suppurative salpingitis with ovaritis. Pus in the tubes has been found at autopsy in 5 cases of girls 7 to 9 years of age. There is always danger that disease of the adnexa, if not immediately noticeable, may appear later on in life, and menstruation is apt to be established with difficulty. In the great majority of cases of vulvovaginitis Veillon and Hallé[3] have found the gonococcus, though its presence, of course, is not necessarily an evidence of venereal origin. In the very acute cases the gonococcus is most often in pure culture, while in other cases it is associated with the normal bacteria of the vagina. Contrary to the experience of Vahle,[4] who found streptococci in the vaginas of 14% of healthy new-born girls after the third day, these observers assert the absence of pathogenic bacteria in healthy children.

Agramonte[5] reports rapid and satisfactory results in the treatment of vulvovaginitis in children, whether gonorrheal or simply purulent, by vaginal flushing with a solution of permanganate of zinc or potassium (preferably of zinc) of the strength of 1:3000. The fluid is delivered by means of a piece of soft drainage tubing from a gravity reservoir under a head of only 12 to 18 in. Cystitis is treated by irrigations of a 1:6000 solution of the same drug. In 30

[5] Med. Rec., Jan. 11, 1896.

cases, excluding 2 with bladder complication, the average time required to effect a cure was only 12⅕ days from the time of onset.

Acute Nephritis from Shock.—Holz[1] notes the appearance of blood, albumin, and casts in the urine of a number of adolescents suffering from the shock following a fall from a height. The urine cleared up after 2 to 4 days. In several cases autopsy showed the lesions of acute parenchymatous nephritis. As none of the cases suffered from head-injury, the influence of a cerebral reflex could not be invoked, and the author therefore assumes a direct reaction of the force upon the kidney structure.

Nephritis in the New-born.—A very suggestive paper by Jacobi[2] on nephritis in the new-born is summed up in the following brief conclusions: Nephritis is a frequent disease of infancy and childhood, and by no means very rare in the new-born. What was formerly considered mere albuminuria, or a transient form of it, we have been taught by improved methods of investigation, mainly by the use of the centrifuge, to recognize as nephritis. A predisposition to nephritis in the young is caused by the fragility of the blood-vessels in the new-born; by the relative imperviousness of the young renal capillaries compared with the large size of the renal arteries; by the feebleness of the young intestinal muscle, which proves insufficient to expel toxic contents; by the extensiveness and size of the young intestinal blood-vessels and lymphatics and the large size of the villi, all of which favor the absorption of toxins. From an etiologic point of view nephritis in the new-born may be —1. *Congestive* (from feeble circulation, congenital heart-disease, asphyxia, or exposure to low temperatures). 2. *Obstructive* (from the physiologic rapid decomposition of the blood of the newly-born; the formation of hematoidin = bilirubin; jaundice; the production of methemoglobin by chemic poisons, such as potassic chlorate, or by excessive heat; or the presence of blood in the uriniferous tubes). 3. *Irritative* (from the presence of uric-acid or hematoidin infarctions, of purpuric or other interstitial hemorrhages, or of microbes and toxins in the numerous eruptive and infectious maladies and in enteritis).

Lithiasis.—In a study of 1621 cases of lithiasis among children in Hungary, Bokai[3] draws attention to the influence of circumcision in preventing the condition. Among 636 boys suffering from stone in the bladder or other part of the urinary tract, only 19 were Israelites—*i. e.* circumcised—a proportion (3%) even inferior to that of girls (4%) in the total number of the cases collected. [This observation is also in accord with that of Hunt in his paper on lithiasis (Cyclopædia of the Diseases of Children, Keating).]

Tuberculosis of the Kidney.—Primary tuberculosis of the kidney in children forms the subject of an excellent monograph by Samuel M. Hamill (from the Pepper Laboratory of Clinical Medicine, Philada., 1896), founded upon a case personally observed, and 54 other cases in children under the fourteenth year collected from the literature. His deductions as to the probable starting-point of urogenital tuberculosis in children are fully in

[1] Münch. med. Woch., No. 34, 1895. [2] N. Y. Med. Jour., Jan. 18, 1896.
[3] Jahrb. f. Kinderh., Bd. xl. S. 32.

accord with those of observers who hold to the descending form. In the entire series there are scarcely any cases that suggest an ascending extension, and these few can be as justly classified under descending extension.

Neoplasm of the Kidney.—Fruitnight[1] has recorded a marked case of sarcoma of the kidney in an infant (Fig. 129), especially interesting for the

FIG. 129.—Sarcoma of the kidney in an infant of 13 months (Arch. of Ped., Dec., 1895).

fact that treatment with the erysipelas-toxin was tried after operative measures were decided against. The child, a boy of 13 months, presented at the first consultation a large protuberance in the right lumbar region and hypochondrium, which had been noticed for only 3 weeks previously. Erysipelas-toxin containing the bacillus prodigiosus was obtained from Dr. Dillon Brown, and daily injections in the gluteal region were made, the dose beginning at 3 and increasing to 17 minims by the 9th injection. When the supply was exhausted an interval of 4 days elapsed before a new supply was procured, and the injections were recommenced, beginning with 2 minims; 15 injections in all were given. A slight acceleration of pulse and elevation of temperature followed each injection, but the temperature never rose above 102° F. Death occurred on the day of the 15th injection. Absolutely no effect was produced

[1] Arch. of Ped., Dec., 1895.

upon size or course of growth or upon the general condition of the patient. In reviewing the cases recorded by Dr. Coley, in which successful results were obtained, Fruitnight calls attention to the fact that in all the cases the sarcomata were located externally, as on the chest, back, clavicle, abdominal wall, palate, hand, sternum, breast, etc., all the locations being accessible to treatment applied in the immediate radius of the disease; none of the cases reported were of internal visceral origin or attachment. The tumor in the present case weighed 4½ pounds. The microscopic examination is interesting from showing the presence of striped muscular fibers and adenomatous tissue in parts. Four cases in young children, 2 of them aged 13 and 16 months, the other 2 about 4 years, have recently been reported by Steele.[1] Two of the cases were operated upon with successful results. One, an infant, aged at the time 16 months, remained well 18 months after the operation; the tumor was classified as a melanoliposarcoma. The second case, a small spindle-celled growth, was in a girl aged 3 years and 8 months. She recovered from the operation, and was well at the time of the report, 4 months afterward. Emily Lewi[2] also contributes a paper on sarcoma of the kidney in children, and tabulates from the literature 60 cases in which nephrectomy was done.

Neoplasm of the Bladder.—Primary neoplasm of the bladder in childhood is sufficiently rare to call attention to a case of multiple small-celled sarcoma observed by Löhr in a female 3¾ years old.[3] The case was submitted to operation by Nitze, but was reported before the subsequent result was known. The author states that only about 30 cases of primary tumor in this viscus in children have been recorded, most of them malignant, and only 1 out of 15 operated upon, a myxosarcoma observed by Gussenbauer, has not been followed by rapid return and death. [It is quite probable that these figures could be considerably enlarged by a study of the literature of other countries.] A somewhat similar case, of American origin, is recorded by Sims[4] in a girl of 3 years. Vesical symptoms had been present for 18 months preceding the examination. The growth, which was subsequently proved to be a myxofibroma, had grown rapidly in the last 3 months, causing obstruction to the flow of urine, with prolapse of the rectum and of a portion of the tumor through the urethra. During preparatory treatment the prolapsed mass slipped back into the bladder, and a portion of it sloughed off and was passed. The growth was found to spring from the anterior wall of the bladder just above the urethra—an unusual situation. As large a portion of the tumor as possible was removed by scissors through the urethra, and the patient was doing well 6 weeks after the operation.

Neoplasm of the Vagina.—D'Arcy Power[5] records a case of primary sarcoma of the vagina in a child of 2 years and 4 months, with a brief epitome of 24 other cases gleaned in rather a hasty examination of the literature. From a consideration of these cases he states that primary sarcoma of the

[1] Ann. of Gynæc. and Ped., Jan., 1896.
[2] Arch. of Ped., Feb., 1896.

[5] St. Bart.'s Hosp. Rep., 1896, vol. xxxi.

vagina is only a specialized form of malignant disease, which may affect any or all of those connective tissues which are involved in the complicated developmental processes associated with the formation of the cloaca. It grows in the connective tissue of the pelvic organs, and extends into the bladder, the urethra, the uterus, or the vagina, being either circumscribed or diffuse; in either form this growth shows an almost constant tendency to be polypoid and multiple—a characteristic which has given the Germans the term *traubensarcom* as applied to this variety of growth affecting the female generative organs. In children primary sarcoma does not run a very rapid course, and does not ulcerate readily nor usually affect the lymph-glands. Prognosis is grave, recurrence taking place quickly after removal. While polypi are often looked upon as innocent growths, such formations about the rectum and generative organs in children are extremely rare unassociated with malignant disease. Complete cure in 1 or 2 cases of primary sarcoma of the vagina in children shows that early and complete removal may be effectual in some instances.

THERAPEUTICS.

Antipyrin.—Comby[1] states that he uses antipyrin with confidence in pediatric therapeusis in spasmodic states like chorea and pertussis, in painful conditions, and in the febrile states attending typhoid fever, pneumonia, and the eruptive fevers. He has frequently given at a dose as much as 50 cgm. per year of age, prolonging its administration for several weeks without observing any accident imputable to the drug. [The doses here given are considered distinctly dangerous by physicians of wide experience in this country. That such doses have been given by Comby without accident is to be regarded as an interesting experience, which doubtless depends upon the rapidity of elimination in childhood.]

Alcohol.—Emmerich[2] agrees with Grosz[3] that there are only two indications for the administration of alcohol to children: 1. In sudden heart-weakness in the infectious diseases and in collapse in the acute gastric catarrh of infants or following great loss of blood; 2. In chronic disturbances of nutrition, such as are found in rachitis, scrofula, and tuberculosis, in which alcohol through its decomposition acts as a food and retards tissue-waste.

Asaprol.—In a series of 58 cases Moncorvo[4] has found that asaprol is well tolerated, producing in healthy infants no appreciable influence upon temperature, pulse, or respiration. In only 2 cases did it give rise to an erythema; this disappeared in 2 days after withdrawal of the drug. In many cases it increases the quantity of urine, notably in malarial fever, but not if albuminuria exists. A property not previously ascribed to the drug is that of checking hemorrhages, 7 instances of which are cited. The dose employed has varied from 4 to 45 gr. in 24 hours, given in sweetened water to which is added syrup of tolu, gooseberry, or canella. In malarial fever it acts by lowering temperature and modifying more or less rapidly the type of the fever, lessen-

[1] La Méd. infant., Sept. 15, 1895.
[2] Arch. f. Kinderh., Bd. xx. S. 226.
[3] Zeit. f. Krankenpfl., 1895, H. 8.
[4] Bull. gén. de Thérap., Mar. 15–Apr. 30, 1895.

ing the malaise, nervousness, and insomnia and the hepatic or splenic congestion. It sometimes gives rise to a profuse perspiration, but less than that produced by the coal-tar derivatives; in acute tuberculosis, however, its antipyretic action is uncertain. In cutaneous affections, diseases of the ear, nose, mouth, and throat, in vulvovaginitis, and in intestinal disorders it acts excellently as an antiseptic, hemostatic, and cicatrizant. In pertussis, applied upon gauze compresses over the perilaryngeal region (1 % solution), it is said to produce rapid curative results.

Tannigen.—Drews[1] speaks favorably of the action of tannigen in the intestinal affections of infants and children. By reason of its tasteless and odorless qualities the drug is readily taken mixed in a teaspoonful of coffee, water, or milk. The average dose is 3 to 5 gr., repeated 3 or 4 times daily.

Trional.—The favorable experience of Claus with this drug [see *Year-Book* for 1896, p. 585] in childhood has been confirmed by Moncorvo.[2] He has found it of value in the wakefulness so common in the early stage of the eruptive fevers, especially measles, variola, and scarlatina, and particularly in the nervous disturbances attending malaria. In 2 cases of tuberculous meningitis the cerebral improvement brought about by trional was marked. In the psychic disorders of cerebral sclerosis and the insomnia which often accompanies subacute or chronic tuberculosis satisfactory effects were obtained. His experience that in painful conditions the drug is not valuable also coincides with Claus's conclusions. The dose varied from 20 cgm. to 1 g. in 24 hours.

TOXICOLOGY.

Alcohol.—Devine[3] records a fatal case of acute alcoholic poisoning in a girl aged 4 years. About 2 ounces of whisky were supposed to have been taken. Shortly after its ingestion she became stuporous, and remained in that condition till death, 22 hours later, with marked signs of pulmonary edema. Medical aid was not summoned till 5½ hours after the drug was taken. The case is interesting for the comparatively small amount of alcohol taken and the rapid progress to a fatal termination with pulmonary edema. The author is led to consider the importance of carefully watching the dose and effects of alcohol administered to children, particularly in chest-cases, since an overdose might produce a fatal pulmonary edema.

Glycerin.—Antichievich[4] records 2 cases in which small quantities of glycerin, used as a vehicle for iodoform-injections, caused toxic symptoms. In the first case, a boy of 8 years, 4 hours after the injection of 15 c.cm. of a 10 % iodoform-glycerin emulsion into a cold-abscess cavity, symptoms of acute nephritis appeared, and yielded only after 3 weeks of active treatment. In the second case, a boy of 11 years, 20 c.cm. of the emulsion were first used, and produced fever with symptoms lasting 3 days; a second injection of 18 c.cm. was followed by hemoglobinuria, succeeded by a polyuria lasting 8 days. A

[4] Arch. f. Kinderh., Bd. xx. S. 91.

third injection of 15 c.cm. of an emulsion in which olive oil replaced the glycerin was followed by no untoward symptoms.

Opium.—Mattison[1] cites a marked case of chronic opium-poisoning in childhood. A baby of 7 months when first seen presented the shrivelled and wrinkled appearance of an old man, and attracted attention by its peculiar solemn manner. The child had been perfect at birth, and had thrived up to the age of 4 months, when, in order to quiet it when fretful, it was given paregoric. It very soon became necessary to give laudanum and to increase the dose, so that when the child was first seen by the physician it weighed only 7 pounds and was shockingly emaciated and extremely weak. It was taking at this time no less than 1 oz. of laudanum daily. The laudanum was reduced 1 drop at each dose, and at the end of 1 month the child had become plump and well again. In the author's experience children had shown a very strong tendency to become victims of morphinism. Abrupt withdrawal of the drug is not to be thought of, but gradual reduction of the dose, together with general tonic measures, constitutes the whole treatment. Tucker[2] stated that he had seen 1 case of congenital morphinism in the offspring of a mother who for several years previously had been addicted to taking morphin and also to smoking opium. At birth the child appeared to be perfectly healthy, but when handed over to a wet-nurse it began to lose ground rapidly. This he attributed to the sudden removal of the baby from the influence of the morphin to which it had been subjected in utero.

NERVOUS AND MENTAL DISEASES.

By ARCHIBALD CHURCH, M. D., and HUGH T. PATRICK, M. D.,
of Chicago.

Outline of the Work and Progress of the Year.—During the past year the current literature, especially on this side of the water, has contained more and more regarding hysteria and its recognition, following largely in the line of the French school. The polymorphism of the disease makes its recognition sometimes extremely difficult, but much has been done to familiarize the profession with the stigmata of the disease. In the matter of diagnosis an article by Patrick is of especial value. Its mimicry of pseudomeningitis is also elucidated in an abstract contained in the following pages. The fact that it sometimes appears in children is generally overlooked, but marked cases are being constantly reported from all over the world that have much in common and serve to establish a type.

In regard to epilepsy the Flechsig treatment is still under advisement. It seems in some old cases to give more relief, at least temporarily, than any other plan of treatment. The optimism that introduced the trephine for focal epilepsy has been gradually disappearing, and the present limitations of this heroic intervention are now being clearly seen. The recognition of the intoxication factor in epilepsy is also now becoming prominent.

Dana recommends the heroic exhibition of strychnin in the treatment of neuralgias, especially of the trifacial; and if others meet with the same success, his contribution to the therapeutics of the disease will mark a distinct step in its management.

Reflex neuroses are being drawn within an ever-narrowing circle which perhaps will eventually see their extinction. The whole subject is admirably summed up by Knapp in an article which is abstracted later on.

The subject of muscular wasting is receiving contributions from all over the world, showing that there is merely a gradation between the so-called progressive muscular atrophy and the idiopathic muscular atrophies or muscular dystrophies. The autonomy of the motor neuron and its trophic functions will probably eventually bring all of these progressive muscular atrophies again into the same classification.

The thyroid treatment of myxedema and cretinism is being established on the firm footing of clinical results, and cases favorably affected by the exhibition of thyroid or by thyroiodin are being constantly recorded. One fact in regard to the relation of the thyroid gland to the economy is now firmly fixed—that lack of its functional activity results in myxedema.

The ever-widening recognition of the relation of the arterial supply to the brain and spinal cord to the etiology and distribution of organic lesions in the central apparatus embraces a number of contributions of importance.

In exophthalmic goiter the tendency is to recognize the condition as due to hyperthyroidation, though this does not well explain all the phenomena of the disease. The question still remains, Why does the thyroid over-act? There are a number of cases showing that the removal of a portion of the thyroid, or otherwise limiting its activity in Graves' disease, exercises a beneficial and often a curative effect.

In tetanus the value of the antitoxins seems less than was at first hoped.

The role played by anemia in the production of changes in the central nervous apparatus is greater than was at first supposed, and cases are being accumulated from far and near showing the prevalence of these changes, especially in the spinal cord, in all forms of pernicious anemia.

The value of Quincke's lumbar puncture is now established as a diagnostic means, and sometimes as a means of treatment, in all cases associated with increased production of cerebrospinal fluid, notably in meningitis.

Cases of syringomyelia are being so rapidly added to the literature that it is evident this disease, which at first was considered a rarity, is one of the not uncommon spinal lesions. It probably has heretofore been considered a curiosity or mistaken for some of the other organic diseases of the cord.

Landry's paralysis seems to be entering the realms of infectious maladies, and especially of infectious inflammatory processes in the cord.

The year has been somewhat barren in pyschiatrical circles.

The polyneuritic pyschoses of recent years are now being recognized as cerebral manifestations of the general intoxication that leads to the neuritis.

The study of heredity continues to widen the field of etiology in all forms of mental disease.

General paralysis seems to be more and more a parasyphilitic condition, and the tendency is growing to consider syphilis as the only cause of paretic dementia.

Thyroid-feeding in insanity has not met with much success. It acts as a mild stimulant in some of the depressed forms of mental disturbance.

NERVOUS DISEASES.

The Diagnosis of Hysteria.—Patrick[1] in a paper on the diagnosis of hysteria calls attention to an important distinctive trait of hysteric anesthesia and hyperesthesia. This is a rapid shifting of the border. If the anesthetic or hyperesthetic area be accurately determined (and it nearly always can be), and the border lightly marked, and the examiner's attention then be directed to the examination of other parts for a few minutes, it will be found on returning to the zone of disturbed sensation that the border has moved $\frac{1}{2}$ to 2 in. (see Fig. 130). This rule applies to most cases of functional trouble (neuralgia excluded) in which there are tender spots along the spine or else-

[1] N. Y. Med. Jour., Feb. 15 and 22, 1895.

where. If the points of maximum tenderness be accurately located and marked with a soft pencil. they will be found 5 or 10 minutes later to have shifted in position. Such a mobility can occur only in functional disease or simulation.

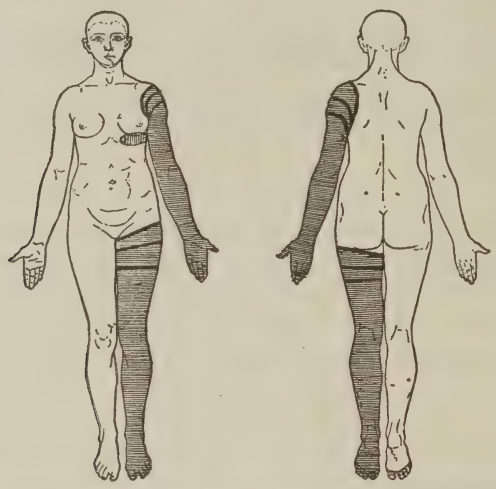

FIG. 130.—Hysterical hemiplegia with most exquisite hyperesthesia. Although the hyperesthesia was so intense and the limits were sharply marked, the shifting of these limits could be demonstrated during the examination, as indicated by the heavy lines (N. Y. Med. Jour., Feb. 15, 1896).

Hysteric Pseudomeningitis.—This peculiar hysteric symptom-complex cannot be exceedingly rare, although scarcely mentioned in English and American literature. Seven cases were reported in 3 consecutive meetings of the Société medicale des Hôpitaux.[1] The first case, reported by Huchard, was that of a woman aged 24, who developed an irregular fever, to which was presently added strabismus, amaurosis, and vomiting; a diagnosis of tubercular meningitis was made. But from some trivial cause she one day had a typical hysteric convulsion, which first disclosed the nature of the case. Comby mentioned 4 cases which he had observed in children, and which are fully reported in the thesis of Roesch. Two of these patients were 14 years, one was 4½ years, and one 9 months [*sic*] of age, and in each instance the original diagnosis was tubercular meningitis. Comby says it is impossible to exclude toxemia as the cause of some of these cases, instead of hysteria, and he prefers the term "meningism," as the cases are similar to those of "peritonism" described by Gubler. Gaillard reported 2 cases. The first, a young woman, had as symptoms intense headache, pain in the epigastrium, persistent emesis, constipation, hyperesthesia, "raie méningitique," and nuchal rigidity, but there was no fever, and she rapidly recovered under proper treatment. The other case was still more striking. A man of 26 presented mental hebetude, general prostration, gun-hammer posture, "raie méningitique," epigastric pain, vomiting, fetid breath, anorexia, hyperesthesia, retention of urine, nocturnal delirium, constipation, and emaciation. There was neither fever nor rigidity back of the neck. After remaining in *statu quo* for some time, the patient, without

[1] France méd., Dec. 20 and 27, 1895, and Jan. 3, 1896.

apparent cause, seemed to suddenly awake as from a dream, began to talk, take nourishment, etc., and a rapid recovery followed. Patrick[1] has reported a case complicated with hysteric blindness. A young woman, aged 30, was attacked with severe pain in the head, which rapidly became more generalized and was accompanied with signs of some systemic affection. Within 48 hours she became totally blind. When seen on the third day the pulse was 120, temperature 100° F.; there were excruciating headache, tenderness and rigidity in the nuchal region, vomiting, constipation, a foul tongue, mental hebetude, general hyperesthesia, and increased reflexes. She also seemed to be deaf in the left ear. At the next examination the diagnosis of hysteria was made, and the symptoms rapidly disappeared under treatment by suggestion. [We have since seen an additional typical case.]

Hysteric Eye-symptoms.—In connection with the foregoing case we might mention one reported by Claude.[2] A neuropathic woman of 29 after an apoplectiform attack presented right hemiparesis, with anesthesia and ocular symptoms on both sides. The hemiplegia was promptly dispelled by hypnotism, the anesthesia persisted, and the ocular symptoms yielded gradually. For the right eye there was amblyopia, dyschromatopsia, monocular diplopia, and loss of pupillary reflex to light. The first three of these symptoms rapidly disappeared, but the last was more obstinate. The left eye presented a more marked amblyopia, which gradually improved, but the pupil remained dilated and unresponsive to light and accommodation. In hypnotic sleep, however, the author was able to dispel both the pupillary dilatation and the lack of reflex, and after that they remained normal. [See case of Booth under *Voluntary Dilatation of the Pupil.*] Kebbell[3] reports 2 cases of hysteric aphonia successfully treated by the application of a spray of ethyl chlorid to the nape of the neck. He thinks it more convenient than electricity and equally efficacious.

Hysteric Contractures.—Weir Mitchell[4] [in a paper containing little absolutely new, but replete with interesting and instructive observations] considers some of the more unusual and severe manifestations of hysteria. The principal point that he makes is that there are two kinds of hysteric contracture—the one local, in which no organic changes occur in muscles or joint, and a generalized form, early affecting several or all extremities, in which the muscles and connective tissue take on a hard, leathery consistence and the reflexes and faradic excitability disappear. In this connection Mitchell misquotes Charcot, saying that he taught that in hysteric contracture there was never sufficient organic change to abolish faradic excitability and to prevent free passive motion under deep chloroform-narcosis, whereas the French savant taught that the exact reverse sometimes was observed. We would particularly call attention to the author's statement that in his wide experience he has never seen a prolonged hysterical contracture suddenly disappear, although he gives credit to the statements of others who have observed this phenomenon. And of almost equal interest at this time is his confession that treatment by metalotherapy, magnets,

[1] Jour. Am. Med. Assoc., Feb. 8, 1896.
[2] Soc. méd. des Hôp., Nov. 29, 1895.
[3] Lancet, Jan. 18, 1896.
[4] Med. News, Aug. 24 and 31, 1895.

and hypnotic suggestion has only ended in defeat. After this we would expect his implied caution as to commanding a bedridden patient to walk. He plainly says that such a command, with failure, means double injury to the case, and that only a wide experience with hysteria will enable one to select the cases for abrupt exercise of authoritative influence. [We dwell upon this because it accords perfectly with our own experience and judgment that in the overwhelming majority of cases of hysteria the most is accomplished by rational, systematic, and continued treatment.]

The one entirely novel fact in the paper, so far as we know, is that in contracture with extreme flexion of the thigh there is often severe pain in the foot caused by the stretching of the sciatic nerve over the edge of the sciatic notch. This assumption as to the origin of the pain is supported by the results of treatment, for in the author's experience extension of the thigh has at once relieved the pain, although it was frequently necessary to divide the tendons to accomplish this.

Among some of the more unusual symptoms due to hysteria, and noted by the author, we think it profitable to mention the following, as they are likely to mislead physicians to a diagnosis of organic disease: incontinence of urine and feces, temperature from 95° to 101°, pulse 130 to 180, respirations too rapid to count, movement of one eye independent of the other, extreme emaciation (child of 11 years weighing 45 pounds), loss of speech, sight, taste, and feeling. One case communicated for a time entirely by means of the eyelids. Loss of pupillary reaction to light and almost complete loss of erections were also noted.

The conclusion of the paper is as follows: "But, whatever the cause, I have seen hysterical contractions in which, after section of tendons, the joints were too much altered to admit of useful restoration. The leg, bent at an angle of 45°, is brought, by section and the screw, to a much larger angle, but cannot be made straight enough for use. There is motion within limits, but with weak muscles and bent legs the effort needed for walking becomes excessive. Under these circumstances crutches are essential, and there may arise a question as to the propriety of making the leg straight by an operation that will leave it rigid. Above all, I desire to impress upon you, finally, that a contracted limb is not a limb to confide to the rare relief brought or not brought by time.

"I have desired to call attention to this paper to certain hitherto unnoticed clinical facts: 1. Two forms of hysterical contracture exist. One concerns single parts and limited groups of muscles. In this the contracture may last for years without the addition of organic changes in muscles, joints, or interstitial tissues. In this also sudden cessation of contracture is possible. 2. A form of contracture exists which attacks in succession one limb after another, until soon or late all or nearly all the voluntary muscles, as well as those of the trunk, may become involved. The cases of this group do not, in my experience, ever get well abruptly. In them the muscles, joints, and areolar tissues undergo serious organic changes.

"In the first or limited form the muscles and the muscular reflexes remain unaltered or are but little changed, and mechanical and electric responses continue to be normal or nearly so. In the second or generalized form the reflexes are lost or interfered with late in the disorder, and the electric responses are quantitatively lessened, and may, in time, be almost altogether lost. It is only in this form, after years of life in bed, that we may expect to see changes in the cord. Whether these are merely independent accidents, or are the rare secondary products of the hysterical condition or of the organic changes this occasions in the peripheral nerves and muscles, we do not yet know."

Hysteric Spasm of the Trunk-muscles.—Janet[1] calls attention to a manifestation of hysteria that has scarcely been mentioned by writers on the subject, but which, he thinks, cannot be very rare, as he is able to report 8 personal cases. This new symptom-group of the "great neurosis" consists of a contracture of the muscles of the trunk—sometimes a few, sometimes nearly all, including the diaphragm. The onset is usually acute, and the contracture may be sufficiently intense to cause not only great pain and induce vicious attitudes, but also to produce various digestive and respiratory troubles, so that the affection may simulate some visceral disease. The following condensed report of 1 of his cases will illustrate: A decidedly hysteric woman, aged 32, was apparently attacked by some acute febrile disease. She complained of headache, backache, and respiratory oppression. The face was pale and drawn, the lips dry, the tongue pasty; respiration was apparently difficult and 45 per minute. Although the pulse was only 75, the temperature 100.7°, and physical examination negative, a diagnosis of acute bronchitis, or perhaps grip, was made and the patient treated accordingly. At the end of a week there was but little change. The temperature was normal and physical examination negative, but there were anorexia, insomnia, constipation, coated tongue, dyspnea, and anxiety. It was now learned that the attack had followed a fit of anger, and examination revealed all the thoracic and abdominal muscles tensely contracted and very tender. The trunk was so fixed that deep inspiration, sighing, and yawning were impossible. The constipation, dyspnea, pains, etc. were also due to contracture, and disappeared as soon as the muscles were restored to their normal condition. In another case, also a markedly hysteric subject, following some emotion or slight shock the trunk would become rigid, almost immovable, respiration rapid, shallow, and almost exclusively superior costal. She would be unable to stoop or even nod or turn the head: she could not take a full breath, cough, yawn, or laugh, and complained that she was compelled to cry in complete silence. The urine had to be drawn, and defecation occurred only once in 2 weeks.

When hysteric patients complain of a smothering sensation, that the chest feels as if in a vice, of extreme constipation, difficult digestion, etc., this condition of contracture should be sought. The patient is asked to assume divers positions of the trunk, execute various movements, and to take deep inspira-

[1] France méd., Dec. 6, 1895.

tions, when it may be found that some of these movements cannot be executed on account of rigid and painful muscles that may at times be seen and felt. The best treatment is massage, which may be employed even when the parts are intensely hyperesthetic if it be begun with extreme gentleness. The muscles are ordinarily not tender at first, but just before they cede to the treatment they become tender and painful, which is thus to be regarded as of favorable import. The treatment is not to be discontinued while the least contracture remains, for such residue may be the point of departure for renewed attacks. Immediately following the cessation of the contracture the patient feels sore, and must for some time avoid quick movements which might also determine a relapse. Aside from the mechanical action on the muscles, massage acts in part by the mental impression it produces; it is more efficient during hypnosis, may succeed when given by one person, fail when given by another, and is ineffective when used by the patient himself. The fundamental treatment of this, as of all hysteric manifestations, must be the rational treatment of the neurosis itself.

Hare[1] reports a case quite similar to those of Janet. A boy of 19 had very severe spasms of pain in the abdomen, which came on every day in the late afternoon or early evening. The time of the attacks is quite characteristic of hysteria. The tongue was heavily furred, and digestion was evidently greatly impaired. On examination both recti muscles were found in a state of rigid contraction, and when touched developed a rhythmic spasm of a rate of about 60 per minute. Under anesthesia the spasm promptly disappeared, and the boy rapidly recovered under gastric lavage and antiseptics. [The question naturally arises whether the gastric trouble was due to the muscular rigidity, as Janet would hold, or the spasm due to toxemia from the gastric fermentation, as occurs in some cases of tetany.] (See *Tetany*.)

Hysteria and Tetany.—[Although hysteria may in its manifestations closely simulate tetany, it should be clearly understood that they are perfectly distinct and entirely different diseases, and Grace Peckham Murray[2] commits a solecism in reporting 3 cases of "hysterical tetany." They were better called hysteric pseudotetany, or, perhaps better still, tetanoid hysteria, as they are cases of hysteria pure and simple.]

Hysteria in Children.—[It is not new that hysteria may affect children, and very young children, but they have very generally been thought to be refractory to the convulsive form of the disease. There is a general, though false, impression too that convulsive hysteria is almost confined to the Latin races, especially the French.] It is instructive, therefore, to know that Fürstner,[3] a German, has observed a number of cases of hysterical convulsions in children under 7, and has made extended observations of 11 cases between the ages of 9 and 16. In both of these groups boys were more frequently affected than girls. The convulsions varied greatly in character, some being frankly hysterical and others closely resembling epilepsy. One boy had fits exceed-

[1] Medicine, July, 1896.

[2] Med Rec., Mar. 21, 1896.

[3] Arch. f. Psych., Bd. xxviii. H. 2.

ingly like procursive epilepsy, and in quite a number of patients the spasms succeeded one another with such rapidity as to closely simulate status epilepticus. The entire differential diagnosis cannot be entered into here, and we confine ourselves to a very few traits. The spurious (hysteric) status does not induce the extreme physical prostration and mental torpor characteristic of status epilepticus. Bromids are absolutely without effect, and Fürstner insists that they produce drowsiness and hebetude with pathologic rapidity. The movements in the convulsion are much larger and more irregular (writhing) than in epilepsy, although they do not attain to the systematic purposiveness seen in adults. Characteristic is also the fact that the little patients have, with great frequency, an unconquerable distaste for food and in consequence may become greatly emaciated. [Fürstner does not mention the fact, but rebellious vomiting or regurgitation is often an accompaniment of this anorexia.[1]]

Hysteric Breast.[2]—The organ is enlarged and very sensitive, particularly the integument, but the affection is one of exacerbations, and between the attacks the breast may be almost normal. During an attack the hyperesthesia may be so intense as to make the mere contact of clothing unbearable, and there are vasomotor disturbances varying from simple congestion to marked edema or even cutaneous gangrene. At the same time the breast is the seat of prickling, burning, or lancinating pain, and may swell to double the normal size. The exacerbations are caused by such influences as ordinarily induce hysteric attacks—intense emotion, menstruation, etc.—and at the height there may be a more or less pronounced convulsion. The appearance of the integument is variable: there may be white, red, or cyanotic edema. The diagnosis is not always easy in the intervals, but is much more difficult during an attack, as all palpation is impossible. The superficial gangrene has occasionally been followed by secondary infection, suppuration, swelling of the axillary glands, etc.

Polyesthesia and Macroesthesia.—Stcherbak and Ivanoff[3] have reported a case of polyneuritis and hysteria presenting curious sensory manifestations in the distribution of the right median nerve. A body touched or held with the thumb and the adjoining two fingers felt larger than it actually was (macroesthesia), and at the same time it seemed as if several bodies of the same kind were felt (polyesthesia). At different times varying sizes and numbers were appreciated. The phenomenon could not be elicited elsewhere than in the region named. Its advent had been preceded by severe pains, paresthesia, and trophic changes, particularly in the distribution of the right median nerve. The paresthesia continued in association with the polyesthesia and macroesthesia, and disappeared with them. There was also impairment of both tactile and muscular sensibility in the affected area.

Neurotic Vomiting.—[It was noted in the *Year-Book* for 1896, p. 660,

[1] See Hysteric Anorexia in the *Year-Book* for 1896, and also the Diagnosis of Hystero-epilepsy by one of us (H. T. P.), N. Am. Pract., July, 1896.

[2] Gilles de la Tourette, Nouv. Icon. de la Salp., vol. viii. p. 107.

[3] Arch. de Méd. exper. et d'Anat. path., 1895, p. 657; Med. News, Nov. 2, 1895.

that in hysteric anorexia and vomiting the patient may not only become emaciated in the extreme, but may even die of inanition.] Edes [1] in a very suggestive paper reports 2 cases with fatal termination. In neither case did the very careful postmortem examination reveal any cause for the vomiting or death. He also reports a third case, in which death seemed imminent, but in which the patient recovered. [All 3 cases seem to confirm the hypothesis advanced by Brissaud and Souques (see *Year-Book* for 1896, p. 660) that the trouble is essentially a mental disease, and that the patient is the victim of a subconscious imperative conception (ideé fixe subconsciente). Indeed, Edes seems to have come to a similar conclusion, as the following remarks will indicate:] "The act of vomiting is to a certain very limited extent directly under the control of the will, but much more completely is it, together with the whole process of digestion, indirectly subject to nervous influence." "How easy it is to disgust a sensitive person with any article of food by some unpleasant detail as to its source or method of its preparation! It is certainly consonant with the views of hysteria held by some theorists that a fixed idea or some incident forgotten as to ordinary consciousness, but retained in the subliminal, may be constantly exciting the centers controlling the action of the stomach. In the second of the cases reported it is more than probable that the idea of the patient that she was not going to get well had a good deal to do with determining the result. If the patient believes that she must vomit, she will do so; if, on the other hand, there are no nerve-endings in the gastric mucous membrane irritated by inflammation or neoplasm, no cells in the medulla to be compressed or poisoned, assurances that she need not and must not vomit are of more value than bismuth, creasote, or ice. One gentleman proposes to check hysteric vomiting by the simple plan of bringing no basin."

Dubois [2] reports 3 cases of hysteric anorexia treated principally by hypodermic injections of morphin. He gives large doses, enough to relieve all pain and quiet the stomach—indeed, to partly narcotize the patient—and gives food one-half hour after the injection. Positive assurances are made to the patient at the same time. The doses are then gradually decreased until the solution used contains none of the drug. [The author claims unusually good results from this treatment, but we would be slow to recommend it, and certainly should not use it until less objectionable methods had failed.]

Irritable Spine.—Gibney [3] gives his treatment of irritable spine. [This term, by the way, we, with him, prefer to spinal irritation.] He [properly] confines this term entirely to cases of a functional character when there is no organic disease of the spinal cord or column. The treatment embraces the Paquelin cautery, blisters, massage, hydrotherapy, and static electricity, all of which are old and useful measures. Something new is the application of strips of adhesive plaster, 4×1 in., obliquely criss-cross along the spine. These means failing, he applies a light brace, which often affords great relief, although he does not report a case so cured. [Although the author insists that

[3] Med. Rec., May 9, 1896.

the cases are functional and at times of an hysterical nature, he does not seem to appreciate that they are generally *psychic*, and he has apparently not noticed the rapid shifting of tender points that can nearly always be demonstrated. (See Diagnosis of Hysteria.)]

Voluntary Dilatation of the Pupil.—It is said that some persons can cause the pupil to dilate by producing the mental image of a dark room, and Brücke has mentioned a physician who could dilate the pupil without this aid. These cases excepted, we believe the case reported by Bechterew[1] to be unique. A nervous woman of 37, after an attack of right temporal pain, noticed that the right pupil was dilated. This was repeated several times, and she then discovered that she could voluntarily dilate it. The dilatation always followed close work, and was regularly present during the 3 days preceding menstruation. [We know of a case in which dilatation of one pupil always accompanies menstruation.]

Booth[2] reports a case of **mydriasis cured by hypnotism.** It was unilateral and disappeared after 7 sittings. Three months later the other eye presented the same condition, and was cured in the same way.

Epilepsy.—[In the *Year-Book* for 1896 we reported upon **the Flechsig treatment** of epilepsy, and another year's experience has confirmed the opinion then expressed that it constitutes an addition to the therapeutics of this disease.] Of more recent communications we may mention that of Nearro,[3] who reports 7 cases. All of the patients improved, and in some the result was brilliant. For instance, one, an imbecile, who under the bromid treatment was having 4 or 5 fits a day, had no attacks in the 6 months following the beginning of the Flechsig treatment. Wolfe[4] reports very fully the case of a girl aged 14 who had gradually grown worse under all methods of treatment, including bromids up to 600 gr. a day, but who at once improved under this treatment (with $\frac{1}{100}$ gr. of atropin added to the bromid), and for 9 weeks preceding the report had not had a fit. Lui[5] reports very good results from the Flechsig treatment. The fits ceased for a variable length of time, and even after their return the duration and frequency of the attacks were not so great. In 10 cases **Bechterew's treatment**—a combination of bromid, adonis vernalis, and codein (see *Year-Book* for 1896)—was used with uniformly good results. In some cases the attacks ceased; in others there was only a diminution in their violence and frequency. Neither of the methods seemed to have any effect on the mental state. Pellizzi[6] treated 25 cases with Bechterew's formula. In no instance did the fits cease, and the author concluded that the treatment was efficacious exactly in proportion to the amount of bromid administered. Guicciardi[7] came to the same conclusions, but found that the bromid was better tolerated in this combination than when given alone. Taty[8] made

a very careful study of the Bechterew treatment in 17 cases. He began with moderate doses, increased about one-fourth at the end of a week and again at the end of the second week, giving as the maximum about 40 gr. of adonis vernalis, 128 gr. of potassium bromid, and 2 gr. of codein in the 24 hours. In the majority of the cases there was an improvement in the frequency and severity of the convulsions, but in a few the effect was *nil.* Sudden cessation of the mixture had the same effect as sudden withdrawal of bromids in causing a rapid recurrence of fits. In quite a goodly proportion of the cases the treatment caused such marked somnolence that it had to be stopped. In short, the bad effects of the bromids were manifest, except the dangerous and homicidal impulses that are observed in connection with the straight bromid treatment, especially on its sudden cessation.

Trional in Epilepsy.—Among the more recent medicaments employed in epilepsy is trional. Boyer[1] reports from the service of Weir Mitchell 13 cases treated by this drug. In all but 1 there was some improvement; in some the remedy accomplished distinctly more than the bromids, and in 1 or 2 the result might be called brilliant. One child was having as many as 5 fits a day, but under trional had none for 6 months, and was, besides, cured of a chorea of 3 years' standing. The conclusion is, that trional may not supplant the bromids, but may be useful in such patients as are not improved by them or when a change of treatment is for any reason desirable.

Potts[2] from the treatment of 17 cases with **horse-nettle** (*Solanum carolinense*) concludes—1. That the drug has a decided influence for good upon the epileptic paroxysm; 2. That this influence is probably not so great or so sure as that obtained by the use of antipyrin and the bromid salts, or even of the mixed bromids; 3. That in those cases in which it is of service it relieves the paroxysms without causing unpleasant symptoms, such as are sometimes caused by the use of large doses of the bromids; 4. That the dose ordinarily recommended (10 to 15 drops of fluid extract) is too small, and that as much as a teaspoonful or more 4 times daily is often needed to secure results. Mackid[3] reports the case of a child of 11, the subject of epilepsy for 3 years, who was having almost daily fits, and had as many as 12 in one day, who was apparently cured (time not stated) by fluid extract of horse-nettle, increased to 1 fluidounce 3 times a day, and afterward 4 oz. once a week.

Peterson[4] considers, among other things, some of the more **recent proposals in the therapy of epilepsy.** Regarding some of the drugs he says: "In the first place, there is **simulo,** a South American plant of the hyssop family, the tincture of which is given in doses of 1 to 2 or 3 drams 3 times daily. After an experience in many cases for several years, I would say of simulo that it deserves trial in most cases; that it is perfectly harmless, which cannot be said of the bromids, borax, belladonna, and some other drugs; that in a few cases it has been extremely beneficial in my hands, and that in most cases it has no effect at all. *Solanum carolinense,* or horse-

[3] Therap. Notes, June, 1896.
[4] N. Y. Med. Jour., June 6, 1896.

nettle, has in my practice proved of no value whatever. The so-called bromid treatment of **Flechsig** is of great use for many patients, especially in old and obstinate cases when all other agents have proved ineffectual. This treatment consists of the administration of opium for some 6 weeks, beginning with ½ to 1 gr. 3 times daily, and increasing daily until 10 to 15 gr. a day are taken, when the use of opium is suddenly stopped and bromids in large and gradually reduced doses are given (30 gr. 4 times daily to begin with). I had used in certain cases of epilepsy for some years codein with considerable success, but this combination of the opiate with bromids is still more satisfactory. *Adonis vernalis* conjoined with the bromids, as recently suggested by Bechterew, is an efficient method of treatment, from which in several instances I have had gratifying results. Digitalis, which has properties similar to *Adonis vernalis*, was formerly frequently given in epilepsy, but the new combination seems to be much more efficacious."

He further says: "There are a few cases of epilepsy in which careful investigation indicates self-intoxication as a factor. In these an excess of ethereal sulphates (indican) in the urine, together with periodical or constant attacks of gaseous diarrhea, are almost positive manifestations of putrefactive or fermentative changes taking place in the alimentary tract. It is remarkable how much benefit may be obtained in such patients by the regulation of the diet (milk and its modifications, kumyss, matzoon, somal, rare or raw beef, eggs, green vegetables, and special breadstuffs, like zwieback, Huntley & Palmer's breakfast biscuits, and Voebt's *biscotte de légumine*); by the frequent drinking of hot water, and the occasional flushing out of the large intestine by hot water; and by the use of certain intestinal antiseptics given 2 hours after meals, such as betanaphtol, salol, salicylate of sodium, and peppermint. The remarkable effects of the thyreoid extract upon general nutrition would naturally suggest the advisability of its administration for experimental purposes in some of the nervous diseases which we are accustomed to look upon as due to nutritional disturbances in the nervous system. With this idea in view I have been treating with thyreoid extract 10 epileptic patients selected as showing a specially obstinate form of the disease and having frequent attacks daily. In all of them there was a loss of weight. In 9 of them there was no apparent effect. In 1 case, however, the result was brilliant enough to justify its trial for a longer time in other cases. In the 6 weeks now elapsed since the treatment was begun the patient has had no attacks, although previously, under any sort of treatment, he averaged 2 or 3 daily."

Regarding so-called **reflex epilepsy** he submits the following: "1. Reflex epilepsy is so rare that the proportion of cases in which a reflex cause will be found is certainly not above 1 or 2 in 1000. 2. In chronic cases, where the epilepsy has had its origin in a reflex cause, the convulsive habit has become so strong that removal of the reflex irritation will seldom alter the course of the disease. 3. There are surprisingly few cases on record in which an operation of any kind whatever for the relief of so-called reflex causes has induced a cure of the epilepsy. I think authentic and trustworthy instances

of the kind recorded in literature could easily be counted upon the fingers. Bearing these points in mind, the practitioner may perform his gynecological operations, circumcise, carry out procedures on the nose, tamper with the eye-muscles, or what not, but let him not be too sanguine of a successful issue. He will be fortunate indeed to meet with a single success."

[It is, perhaps, but just to say that Ranney, a great apostle of the treatment of epilepsy by graduated tenotomies of the eye-muscles, has taken violent exception to these postulates. It is also but just to say that he is supported by exceedingly few good observers.]

As to the value of brain-operations for epilepsy Peterson sums up as follows: "1. In about 1 % of all cases of epilepsy an injury to the head will be found to be the original cause. 2. In a much larger percentage an old meningeal hemorrhage, congenital or acquired in infancy, giving rise, in addition to the epilepsy, to various degrees of paralysis, idiocy, or other cerebral symptoms, and presenting, on examination, brain-atrophy, sclerosis, and cysts as sequelæ to the primary lesion, will be ascertained to be the cause. 3. In the present state of our knowledge and experience those cases due to meningeal hemorrhage should not be operated on at all. 4. In the very small number of cases having injury to the head as a cause the epileptic habit is so strong and the changes in the brain are usually so old and deep-seated that an operation, as a rule, does not cure, and only seldom permanently diminishes the frequency of the attacks. 5. Of miscellaneous traumatic cases where a surgical procedure seems justifiable and is undertaken, a cure may be reasonably expected in perhaps 4 out of every 100 cases operated upon. 6. The removal of a cicatrix from the cortex supposed to be the epileptogenic nidus will naturally be followed by the formation of a new cicatrix in the surgical wound, and is scarcely a defensible procedure. 7. The more recent the injury the greater will be the promise of lasting benefit. If 100 cases of epilepsy could be selected in which the trauma dated but a few months back, trephining and ablation of the morbid tissues would doubtless prove curative in a very large percentage of cases."

Trephining for Epilepsy.—Mason[1] tabulates from the literature 26 cases of trephining for epilepsy, in addition to his former table of 44.[2] Of these 26, only 1 can be regarded as cured, 4 improved, and 1 is doubtful. The remainder, 77 % of the whole, were either unimproved or the time elapsed after the operation was too short to allow of conclusions. Of the entire 70, the author reckons only 3 as cured and 6 improved. Of the 26, none died from the operation; of the 44, 3 were fatal. The following principles enunciated by the author are not particularly new, but, we think, fairly represent the best neurologists and surgeons of to-day: "1. Always consider an epileptic fit as a symptom of some underlying condition. 2. Inquire particularly and very carefully about the first convulsion: What was its apparent exciting cause; what was its character, general or affecting only certain portions of the body; and what portion of the body was affected at the beginning of the fit? 3. If there

CARE OF THE BABY.

A MANUAL

FOR

MOTHERS AND NURSES.

BY

J. P. CROZER GRIFFITH, M. D.,

Clinical Professor of Diseases of Children in the Hospital of the University of Pennsylvania; Professor of Clinical Medicine in the Philadelphia Polyclinic; Physician to the Children's, to St. Agnes', and to the Methodist Hospital, etc.

400 PAGES. PROFUSELY ILLUSTRATED.

PRICE, $1.50.

This work contains practical directions for the care and management of children in health and disease. It is written from the standpoint of the physician, but is adapted to the use of the mother and the nurse, and includes such advice as is required in treating minor ailments, and what to do until the doctor comes in serious disease.

Sent post-paid on receipt of price.

925 Walnut Street, Philadelphia, Pa.

"The whole book is characterized by rare good sense, and is evidently written by a master hand."—*American Journal of Obstetrics.*

"Full of that good common sense which the subject so strongly demands."—*New York Medical Journal.*

Although only just published, this work has been adopted by over 60 Medical Colleges.

Diseases of Women.

BY

HENRY J. GARRIGUES, A.M., M.D.,

Professor of Obstetrics in the New York Post-Graduate Medical School and Hospital; Gynæcologist to St. Mark's Hospital in New York City; Gynæcologist to the German Dispensary in the City of New York; Consulting Obstetrician to the New York Infant Asylum; Obstetric Surgeon to the New York Maternity Hospital, etc.

One Very Handsome Octavo Volume of about 700 pages, Illustrated by Numerous Wood-cuts and Colored Plates.

Prices: Cloth, $4.00 net; Sheep, $5.00 net.

A practical work on Gynæcology for the use of students and practitioners, written in a terse and concise manner. The importance of a thorough knowledge of the anatomy of the female pelvic organs has been fully recognized by the author, and considerable space has been devoted to the subject. The chapters on operations and on treatment are thoroughly modern, and are based upon the large hospital and private practice of the author. The text is elucidated by a large number of illustrations and colored plates, many of them being original.

Sent post-paid on receipt of price.

W. B. SAUNDERS, Publisher,

"We prophesy for the book a popularity which will be as great and as well founded as are its intrinsic merits."—AMERICAN JOURNAL OF THE MEDICAL SCIENCES.

"One of the few really good books on gynecology for the general practitioner."—NEW YORK MEDICAL JOURNAL.

was an aura, investigate it carefully, as it will not infrequently give a clue as to the seat of the lesion. 4. If there has been a trauma or a suspicion of trauma, shave the head and look carefully for a scar or a depression. If there is evidence of a trauma in a position corresponding to the initial symptoms of the fit, an operation is usually justifiable. 5. If you cannot get a clear history of the case, give a placebo and place the patient under competent surveillance until you can satisfy yourself as to the character of the fits. 6. Do not operate on a porencephalic child and expect to cure the epilepsy. Do not, as a rule, operate on a case of posthemiplegic epilepsy in a child and expect to cure. 7. Do not operate on an old, idiotic epileptic, a victim of idiopathic epilepsy, with general convulsions of years' standing. What, then, is the value of operative interference in the treatment of epilepsy? In the light of our present experience I think it will be fair to put it thus: *a*. A certain small percentage of the cases will be cured. *b*. A certain larger percentage will be improved. *c*. An even larger percentage still will not be improved at all. *d*. An operation upon almost any case will produce a temporary cessation of fits."

In such a case as that reported by Turner[1] there could not be two opinions as to the advisability of operation: A seaman had been struck on the head 4 years previously by a large iron hook, rendering him unconscious for 7 days and inflicting a depressed fracture of the vertex. After the immediate effects of the traumatism had disappeared he was left with hemiparesis of the left side, constant headache and drowsiness, defective vision and speech, and subject to frequent epileptoid convulsions of the Jacksonian type. Examination revealed a transverse depression a little anterior to the lambdoidal suture, large enough to receive the tips of 3 fingers to a depth of $\frac{1}{2}$ in.; also a discharging sinus at the inferior angle of the right parietal bone, through which a probe passed inside the skull and 4 in. toward the depression. Operation disclosed an epidural abscess, which was evacuated, the walls were curetted, a sequestrum of the inner table removed, and the patient went on to complete recovery from both paresis and epilepsy; at least there had been no recurrence 2 months after operation.

Epileptoid Fits from Autointoxication.[2]—A man of 50 who suffered from chronic constipation would become, about once a week, incapable of mental effort, dizzy, and have a full feeling in the head. Once a month to once in 6 months he would have more severe attacks—would rise in the morning in a semi-delirious state, be very irritable, and later have a typical epileptoid convulsion. General treatment was of no avail, but on Hunyadi water on rising, with a pill of ext. chiretta gr. 2, leptandrin gr. $\frac{1}{2}$, podophyllin gr. $\frac{1}{5}$, euonymin gr. $\frac{1}{2}$, creasote gr. $\frac{1}{2}$, he fully recovered, and during 9 months of observation had no further trouble.

Neuralgia.—Dana, at the last meeting (1896) of the Association of American Physicians,[3] advocated a treatment of tic douloureux of which the hypodermic injection of strychnin constitutes the most active part. The injections

[1] Lancet, Jan. 11, 1896.

[2] Hare, Medicine, July, 1896.

[3] Boston M. and S. Jour., July 2, 1896.

are made once a day, and the dose is gradually increased from $\frac{1}{30}$ gr. to $\frac{1}{5}$ or $\frac{1}{4}$ gr., 10 to 20 days being required to reach this maximum. He says that the large doses sometimes have an immediate anodyne effect like that of morphin, and indeed these were the cases that showed the best results of the treatment. In a few instances the strychnin seemed to temporarily increase the pain, but this was rare. Six cases (another report says 8) were reported, 2 in women, 4 in men, and all were relieved but 1. The ages of the patients ranged from 43 to 73 years, and the duration of the disease before the treatment was begun averaged 6 years. As adjuvants to the injections the author used potassium iodid and iron, rest in bed, light diet, and diluents. The period of relief in the 5 cases had been from $1\frac{1}{2}$ to 2 years. In the discussion Putnam said he had been moderately successful with aconitin, but would be glad to try the new method. Janeway said it was very difficult to get reliable aconitin, but when a good article was used the results were often very good. Sinkler thought the accessory treatment used, the rest in bed at an even temperature, removal from worry, and the like, would of themselves account for considerable improvement. In answer to questions Dr. Dana said he thought suggestion might have had something to do with the results; he had never seen any ill or peculiar effect upon the mind. He considered the element of rest important, but 1 or 2 of the cases had recovered without taking much rest. He did not pretend to explain the good results of the treatment, but the good results were obtained. Most of the cases reported had received all manner of drugs before the treatment indicated was tried. Hunsberger[1] used aconitin in 57 cases of various kinds of neuralgia, and thinks it superior to any other remedy, even operation. In trigeminal neuralgia he gives $\frac{1}{200}$ gr. every 2 hours, and has never seen any injurious effects—no depressive action on the heart, and none of the unpleasant symptoms produced by morphin, atropin, and other alkaloids. In intercostal and visceral neuralgias he finds the remedy particularly efficient, due, in part, to the fact that it does not irritate the digestive tract. In sciatica he gives the drug in small doses for 2 months, and repeats this course after an interval of 2 weeks. Seagrave[2] advocates the injection of cocain for all kinds of neuralgia, as well as for all cases of muscular rheumatism. The solution is introduced over the seat of the pain, except in neuralgia of the head and face, when the injection is made into the arm. They are used as often as the pain returns. The author says: "The markedly good results obtained by injecting cocain into the arm for neuralgia of the head and face cannot, however, be explained on the ground of its local anesthetic effect, and must probably be due to vasomotor influence. That it does act like a charm in many such cases in which all other drugs, morphin included, have failed, my own personal experiences enable me to affirm. In no cases have I seen dangerous symptoms arise from the use of the drug, and in only very few have I observed slight temporary discomfort." [The author says nothing of the formation of the cocain-habit, but we would consider this a real danger and a valid objection to the treatment, except in emergencies and hopeless cases

[1] Therap. Gaz., Aug. 15, 1895.

[2] Brit. Med. Jour., Feb. 8, 1896.

in which morphin would otherwise have to be resorted to.] Nencki and Jaworski[1] have found apolysin of decided value in neuralgia. They have given this name to a new compound chemically of the same group as phenacetin. The dose is from 2 to 15 gr. 3 times a day, and no unpleasant effects were observed; but the drug is contraindicated when the stomach is empty or in a hyperacid condition.

Sciatica.—Negro[2] has reported 113 cases of rebellious sciatica treated by compression, all of which ended in recovery. The procedure is as follows: The patient lies on his face with his legs extended and resting easily one against the other. The most painful spot is selected, the region where the nerve proceeds from the large sciatic opening. On its trunk both thumbs are applied, and it is compressed with the greatest possible force; at the same time slight lateral movements are made without changing the point of pressure or moderating its intensity. This takes from 15 to 20 seconds, and is followed by an interval of 20 minutes' rest, when the procedure is repeated. After a second application, which is much less painful than the first, the patient is able to walk, and for several hours, or even a day, he may be free from pain. In order to obtain complete recovery, says the author, this procedure should be practised about 6 times a day every 2 days, until the definite suppression of the neuralgia is obtained. Monell[3] reports 9 cases treated by static electricity. He used sparks from a ball electrode over the painful points and along the nerve, and the results as reported are certainly remarkably good.

Reflex Neuroses.—The paper by Knapp[4] on this subject is so well arranged and condensed that an abstract is almost impossible, and we content ourselves with a few extracts. [The opinions and conclusions of the author may be taken as fairly representative of the position of the best neurologists upon this important and much-agitated question.] "In order definitely to determine whether the doctrine of reflex neuroses is one which can be accepted, we must first define it. It may be fairly stated, I think, in this way: A slight change occurs in some organ, not sufficient to attract particular attention to the organ itself, to interfere materially with its functions, or to cause noticeable pain or discomfort in it. This change irritates the terminal sensory nerves of the affected organ, and the irritation is communicated to connecting fibres of the ganglionic or spinal nerves, and thus conveyed to a distant organ, which may be anatomically healthy. This irritation may excite in the distant organ phenomena which simulate a morbid condition in it, the organ responding 'most violently to this slight abnormity, as the alarm-gong sounds in answer to the tap on the button of the distant station.'"[5]

"We have all of us heard how the gynecologist has seen 'an agonizing asthma cease shortly after the placing of a pessary, intense cardiac pains and insomnia vanish upon the insertion of a tampon, and a single application of

[5] Engelmann, "The Hystero-neuroses," Mann's System of Gynæcology, ii. 59.

electricity cause a violent dyspnea, with great nervous depression, to disappear even during the application, whilst the patient was still upon the table, though haunted by suffering and reduced to invalidism for over two years. . . . . Even violent psychoses, such as mania, melancholia, and epilepsy, will disappear completely upon relief of the uterine lesion.'[1] Few of us, however, have met with such cases in our own practice, and they seem to be growing much rarer. In my own experience I do not recall a case where the nervous condition was materially benefited by treatment of the pelvic organs unless there were definite local symptoms of pelvic disease; and even with actual local disease the treatment of the nervous conditions may greatly relieve the local symptoms."

"When in the discussion before the Association of American Physicians in 1891, where the neurological side was so ably sustained by your president, Dr. Lusk could say that he was 'tempted to assert that the performance of normal ovariotomy for epilepsy and insanity is to be regarded as hardly better than malpractice,' we may conclude that the operation is following the course of the 'star of empire,' and is seldom performed in our Eastern cities."

"Granting that the hypothesis of reflex neuroses, as stated in the beginning of this paper, be sound, there are certain very remarkable peculiarities which remain to be explained. Why, for example, should disease of the ovary cause so much more nervous trouble, and so much oftener demand removal of the organ on account of the nervous trouble, than disease of the testicle, which has similar anatomical nervous relations? Why should an inflammation of the mucous membrane of the cervix uteri cause so much more nervous disturbance than a gleet? Why is the whole notion of reflex neuroses from uterine disease to-day decadent, while the doctrine of reflex neuroses from eye-strain is dominant? Why are the reflex neuroses from diseases of the nose coming into prominence, while the reflex neuroses from diseases of the larynx are seldom mentioned? Why do we so seldom hear of reflex nervous troubles from diseases of the joints? In all these cases there is equal reason to suppose an irritation of terminal sensory nerves, and in all these cases there is a communication between these nerves and other ganglionic or spinal nerves which can convey the irritation to a distant organ."

"Given a moderate error of refraction in the form of hypermetropia or astigmatism, or given insufficiency of some of the external muscles of the eye, it may be compensated by unusual effort of the muscles of accommodation or of the external muscle at fault. This unusual effort gives rise to the ordinary result of any unusual muscular effort—fatigue, a heavy feeling, and pain. Weir Mitchell long ago pointed out the influence of errors of refraction in causing headache, and cases of headache from this cause are met with daily by all of us. Like most neurologists, I have made it almost a routine practice to refer all patients with obstinate headache to an oculist, and often with satisfactory results. Unfortunately, however, even when an error of refraction or a muscular insufficiency is present, the treatment of the ocular condition does not inevitably lead to a cure, and I have more than once had to regret my

[1] Engelmann, loc. cit., p. 80.

rash promise of relief after I had urged a pretty woman to wear the obnoxious glasses. Cases such as I have just cited, where every form of ocular treatment gave only temporary benefit, have not been unique in my experience, and it has sometimes happened, even where there was astigmatism or hypermetropia, that ocular treatment did no good at all."

"In a few cases of blepharospasm and habit-spasm affecting the muscles about the eye a correction of errors of refraction has given marked relief; in other cases, however, such correction has been of no avail. In most cases where there has been relief, in my experience, there has been a marked neurotic condition, and the trouble may have been of hysterical origin. It is possible, however, that with the extreme muscular effort at accommodation there may have been an overflow of nervous energy to the neighboring muscles."

"Stevens, however, and various writers since, have urged that eye-strain from errors of refraction was of much importance in the production of epilepsy, chorea, and other nervous affections. For a year I referred every case of chorea to an oculist, who corrected all errors that required it. In a few cases the ocular treatment relieved the headache, but it had no perceptible effect on the chorea. I may add that I had no belief that treatment of the eyes would cure the chorea, but I referred them to the oculist at his request. To attribute a disease of limited duration, occurring chiefly in neurotic children, and coming on most frequently in the spring, often attended with fever, endocarditis, and arthritis, and probably of infectious origin—to attribute such a disease as this to a permanent cause like eye-strain seems absurd."

"Epilepsy, much more than chorea, is one of the diseases which rests most distinctly upon a neurotic basis. It is, in fact, an indication of pretty profound degeneracy. The recent work of Chaslin, Van Gieson, and others indicates very strongly that it has a definite anatomical basis in processes of neuroglia-sclerosis in the brain-cortex. In spite of the benefit which is alleged by Dodd, Ranney, and others to follow treatment of the ocular conditions, it is asking too much to suppose that the degeneracy or the cortical changes are the result of astigmatism or any form of phoria. In epilepsy, as in other forms of nervous disease of degenerate type, various stigmata of degeneracy—cranial asymmetry, malformations of the ear, torus palatinus, anomalies of the genitals, etc.—are common. Astigmatism may itself be such a stigma, and the fact that in epileptics Féré has found astigmatism most marked on the same side as other physical deformities is certainly suggestive."

"There is a class of cases, however, where the reflex origin seems fairly probable—the cases of so-called reflex epilepsy. A critical examination of the cases reported under this head would certainly eliminate many of them. A considerable number of them are undoubtedly cases of hysteria, and in others the dependence of the epilepsy upon the alleged source of irritation is certainly doubtful. Nevertheless, the thesis that a remote irritation may give rise to convulsive seizures is supported by the well-known experiments of Brown-Séquard, producing epilepsy in the guinea-pig by injury of the sciatic,

and by a limited number of authentic cases in man. In most of these cases the source of the epilepsy has been of traumatic origin, and on removal of the irritation the epilepsy has ceased. These cases, however, are distinctly rare."

"In these cases it is possible that the constant irritation of the sensory nerves, associated, perhaps, with the shock of an injury, may finally result in a motor discharge, giving rise to a pure reflex epilepsy. Such cases, however, are rare, and further investigation is necessary."

"The following conclusions seem justified: 1. The essential feature in the production of many neuroses is the neuropathic state—the degeneracy of the subject. 2. In hysterical subjects suggestion plays an important part both in the development and in the cure of the symptoms. 3. Disease of any organ may give rise to referred pain in some definite area, but not to other nervous disturbances, except as a secondary result of local disease of the organ. This local disease manifests itself by the ordinary local symptoms, and the nervous phenomena are due to exhaustion, anemia, intoxications, etc. 4. In a few rare cases injury of a sensory nerve may give rise to epileptiform seizures. 5. Surgical operations for the relief of nervous symptoms should never be performed unless there are clear indications, apart from such symptoms, for an operation."

Akinesia Algera.—In the *Year-Book* for 1896, p. 600, reference was made to an exceedingly severe case of this affection reported by Erb, in which remarkable improvement had taken place, contrary to the rule. He more recently reports further improvement, indeed almost complete convalescence.[1] [This fact, together with the entire history of the case, would tend to show the correctness of our expressed opinion that the affection is not to be regarded as a pathologic entity, but only as "a manifestation of already well-known neuroses."]

Hiccough.—Lépine and Viaud[2] report a case of rebellious singultus (the latter physician being himself the sufferer) cured by protracted traction on the tongue. This maneuver resembles that recommended by Nothnagel—elevation of the hyoid bone—but is easier to execute. Bandhapadia[3] relieved a very severe case occurring in the course of remittent fever with bloody diarrhea by causing the patient to inhale the fumes of burning paper. [We have elsewhere seen notes of a case cured by the severe sneezing induced by snuffing capsicum into the nose, and we might mention that Matthieu recommends the sufferer to breathe vigorously and regularly from 45 to 50 times a minute. This expedient is said to sometimes arrest the most violent and persistent attacks.]

Birth-palsies.—[It is sufficiently well known that idiocy, imbecility, spastic paralysis, athetosis, and epilepsy are sometimes caused by injuries received by the babe in difficult labor. These lesions have been supposed to be principally meningeal and of the convexity, although hemorrhage or laceration of the centrum ovale is known to have occurred.] To better illuminate the patho-

[1] Deutsch. Zeit. f. Nerv., Bd. viii. H. 5 u. 6. [2] Prog. méd., May 16, 1896.
[3] Indian Med. Rec., Feb. 1, 1896.

logic anatomy of such cases Schultze[1] has examined the brain and spinal cord of such infants as died soon after prolonged or difficult labor, and reports 3 such cases. The result is interesting, inasmuch as no lesions whatever of the brain itself were discovered, and only slight hemorrhages between the dura and pia, but in the medulla oblongata and spinal cord there were distinct hemorrhages, some macroscopic, many more microscopic. There were also some lacerations in the substance of the cord, and the author [we think reasonably] concludes that such lesions must play an important role in some of the cases heretofore thought to be cerebral. Interesting also is the possible relation of such injuries to syringomyelia. The hemorrhages were most frequent and pronounced just in the location where syringomyelia ordinarily begins, and it is not difficult to suppose that such lesions at birth might later in life lead to processes which constitute the pathologic basis of syringomyelia.

Atypical Muscular Dystrophy.—Pearce[2] reports one of the atypical, possibly transition, cases of progressive muscular atrophy that are constantly coming to view now that a careful examination of such cases has become general. The patient, a married woman aged 59, had begun 27 years before to suffer from weakness of the third and fourth fingers of either hand. In a few years the process had extended sufficiently to produce double wrist-drop and difficulty in walking, the extensors being always affected earlier and to a greater degree than the flexors. Eighteen years after the onset she was examined by Weir Mitchell, who found that, although the weakness was widespread and marked, there was atrophy of the dorsal interossei only. There was partial reaction of degeneration. The paralysis continued to gradually increase in extent and degree until the patient was helpless, but the face was never affected and the neck-muscles to only a slight degree. Sensation was normal, there was no fibrillary twitching, and the mind was unaffected to the last. She finally died of pneumonia. The microscopic examination of the spinal cord, as well as that of the sciatic and median nerves, was entirely negative. The muscles showed atrophy, fatty degeneration, and other conditions characteristic of idiopathic muscular atrophy. [It is to be regretted that the terminal filaments of the motor nerves were not examined nor the cells of the cord by the Nissl method.] The case shows that muscular dystrophy (idiopathic muscular atrophy) may begin in adult life, affect first the small muscles of the hand, and present reaction of degeneration. The marked predominance of the extensors in the progress of the paralysis is also anomalous.

Treatment of Alcoholism.—Dunham[3] emphasizes the undoubted fact that treatment is ordinarily entirely too brief. It should extend over at least 2 or 3 months. In the acute stages he relies on bromid and chloral, with $\frac{1}{150}$ to $\frac{1}{100}$ gr. of hyoscin hydrobromate, when there is pronounced delirium and strong pulse. Hypodermic injections of strychnin sulphate or nitrate, with a little digitalin, are used to strengthen a weak heart, and they may also relieve the delirium. He also recommends the following tablet to be used hypoder-

[1] Deutsch. Zeit. f. Nerv., Bd. viii. H. 1. [2] Univ. Med. Mag., May, 1896.
[3] Quart. Jour. of Ineb., Oct., 1895.

mically: gold and sodium chlorid, $\frac{1}{24}$ gr.; strychnin nitrate, $\frac{1}{60}$ gr.; nitroglycerin, $\frac{1}{300}$ gr.; atropin sulphate, $\frac{1}{200}$ gr.; digitalin, $\frac{1}{60}$ gr.; sodium chlorid, $\frac{1}{8}$ gr. A platinum needle must be used, as the gold corrodes others. This formula is used in the acute and also in the chronic stage, and in the latter he gives in addition a tonic of nux vomica, hydrastis, capsicum, and infusion of gentian. In the after-treatment and the later conduct of the patient he insists upon total abstinence, instead of an effort to confine indulgence to beer and cider. [This is certainly the only rational plan. The foregoing, in addition to proper feeding, good hygiene, and the necessary treatment of complications, is, on the whole, a good method of treatment, but we should hope that no one would adopt it as routine. The formulæ are very good, but unnecessarily complicated—at least the proportion of the ingredients will need to be greatly varied to meet the requirements of individual cases.]

Thyroid Treatment of Myxedema and Cretinism.—[That administration of thyroid is the best, indeed the only treatment worthy of the name, for myxedema and cretinism, is unquestionable, but the constant query is, "Can they be cured, and will they not relapse even if the remedy be continued?"] Murray[1] thinks a favorable answer may now be given to these questions. He says, in substance: Myxedema is a symptom or combination of symptoms of loss of the function of the thyroid gland. In the idiopathic form it is a symptom of chronic interstitial thyroiditis, just as anasarca may be a symptom of renal disease or ascites of hepatic disease. The myxedema can be cured, although the chronic interstitial thyroiditis still remains. As myxedema is thus a symptom of thyroid inadequacy, it occurs not only as a result of removal of or fibrosis of the thyroid gland, but also in rare cases in consequence of other diseased conditions of the gland. In illustration of this, says Mr. Murray, 2 interesting cases which have been observed by Köhler may be mentioned. In one the myxedema developed in consequence of syphilitic disease of the thyroid gland, and as this improved under treatment by potassium iodid the myxedema disappeared. In the other the myxedema occurred as a result of actinomycosis which affected part of the thyroid gland. Great improvement in the myxedema followed the removal of the infected tissues by surgical measures.

In myxedema which accompanies fibrosis of the thyroid gland, we cannot restore the gland to its normal condition, but we can restore the patient to health if no incurable complication has arisen. For example, says the author, a gentleman, aged 44, who had suffered from myxedema for about $2\frac{1}{2}$ years, was sent to him 3 years ago. At that time he suffered from well-marked myxedema. He could scarcely walk half a mile and could undertake no work. Under treatment with thyroid extract rapid improvement took place, so that in 6 weeks the myxedema had almost entirely disappeared; 5 months later he wrote to say that he was quite cured. So complete has been the recovery of his mental and bodily capabilities that $1\frac{1}{2}$ years ago he was able to undertake the duties of secretary to a large manufacturing company, and not long afterward he was able to ascend a mountain over 3000 feet high, with a walk of 10

[1] Brit. Med. Jour., Feb. 8, 1896.

miles, without feeling much fatigue. A daily dose of 10 minims of thyroid extract is sufficient to keep him in good health.

In order to show that patients remain free from myxedema as long as they take thyroid extract and without any increase in the dose, the author refers to the first case in which the treatment was adopted. This patient, he says, was a woman of 46 who had suffered from myxedema for 4 or 5 years. There were well-marked swelling of the face, of the hands, and of the feet; dry skin, without perspiration; loss of hair; subnormal temperature; languor and slowness of speech and action. It is now $4\frac{1}{4}$ years since the treatment was first begun—in April, 1891. She gradually lost all the symptoms of myxedema, which, however, partly returned on 2 occasions when the use of the remedy was discontinued for a time. She has for a long time been free from myxedema, and is so now. The swelling has gone and the skin is soft and moist; the hair has grown again, the temperature is normal, and she leads an active life as the wife of a workingman. She continues to take a dram of thyroid extract during each week. As this patient remains well at the end of more than 4 years, it is evident that as long as she continues to take the extract she will not have myxedema, even if she lives for 20 years more. This continuance of good health in the adult, says Mr. Murray, gives us all the more reason to expect that cretins, if treated early and continuously, will also grow up and develop into normal adults. It will, of course, he says, take years to prove this, but he has brought forward these observations, as they help to show that in cretinism it is well worth while to persevere with the treatment year by year with this object in view.

Maxey[1] reports a typical case that improved with such rapidity that the patient was apparently well in 6 weeks. Bloom[2] reports a case showing recurrence on withdrawal of the remedy. The patient was a woman of 42, and was discharged cured after 72 days of treatment with thyroid. In less than a year she returned in the same condition as when first seen. Instead of the former treatment, she was now put on protonuclein, which seemed to act equally well, as she was again apparently cured in about $2\frac{1}{2}$ months. Fox[3] reports a case that was at first mistaken for anemia with edema, and rapidly grew worse on iron and nux vomica. Improvement on thyroid was marked, but even a few days' cessation of treatment caused her to lose ground.

[The cases of sporadic cretinism treated with thyroid during the last year are entirely too numerous to be cited in detail. The following instances, with illustrations, in addition to what has been said regarding myxedema, will suffice to show what may be expected from this comparatively new treatment. We must, however, caution against the careless and too liberal use of the remedy and against too sanguine expectations in old cases.] One of the brilliant results is reported by Noyes.[4] A child of 2 years had the appearance of an infant of 6 months, and was a typical myxedematous cretin. It was given at first 5 gr., afterward 1 gr., of thyroid extract per day, and at

[1] Med. Sentinel, Dec., 1895.
[2] Phila. Polyclinic, Dec. 28, 1895.
[3] Marat. Med. News, Nov., 1895.
[4] Jour. Nerv. and Ment. Dis., May, 1896.

the end of 5 months had grown 8 in. in length, gained from 3 to 4 lb. in weight, and exhibited great mental improvement. In the discussion of Noyes's paper Leszynsky reported a case in a man of 25, who acted like a child and who was but very little improved by thyroid. Fisher referred to a family of 3 cretins in whom the thyroid treatment was absolutely negative, but he had seen considerable improvement in intelligence, even in patients as old as 40. Haskovec's case[1] is somewhat unusual: A servant-girl of 36 was normal until the age of 8, when she began to grow stupid and gradually became weak-minded, could not be taught to read or write, developed a goiter, and at last became quite idiotic; her speech was almost unintelligible and she at times had delusions. During 9 months of observation in the asylum her condition remained unchanged, pulse and temperature subnormal. After the administration of thyroid was begun the temperature was slightly elevated, respirations accelerated, and pulse 84 to 132. She first became restless and irritable, then began to notice her surroundings, and finally became good-natured and greatly improved mentally. The goiter greatly diminished in size, but she rapidly lost weight and appetite, sweat much, began to vomit and grew very weak, so that the remedy had to be discontinued.

Plate 10 represents a case reported by Vinke.[2] A child of 6 years, about

the size of one of 2, was idiotic, could walk only a few steps, and presented the usual deformities of cretinism. The anterior fontanel was still open. On

Sporadic cretinism. FIGS. 1, 2.—Appearance when treatment was begun. FIG. 3.—After five months' treatment with thyroid extract. (From photographs furnished by Dr. H. H. Vinke.)

thyroid there was immediate improvement. In 2 months he grew over an inch, lost 22 pounds in weight, did not sleep excessively, as he had done before, was mentally improved, and the fontanel was almost closed. At the end of 5 months he was still more improved in every way and the fontanel was closed, but he was still considerably in arrears of children of his age. Parker[1] records a remarkable case of cretinism with goiter. Figure 131 shows the child's condition at 18 years of age, at which time she was easily mistaken for a child of 2 or 3 years, weighed 36¼ lb., and was 33 in. long. She was given ½ of a 5-gr. tablet daily, and in 1 week had improved bodily and was able to say "dad," "mam," and "bab" for the first time in many years. By the end of the seventh week she had grown 1½ in. The dose was increased to 5 gr. a day, and at the end of 3½ months she could stand, which she had never been able to do. She continued to improve physically and mentally, got a new crop of hair, and cut 2 incisor teeth. Figure 132, from a photograph taken less than 6 months after the beginning of treatment, shows sufficiently well the physical and mental change.

Peterson and Bailey[2] report 7 personal cases and tabulate 40 from the literature. In none of these did the remedy fail to cause an improvement when properly and adequately given. The treatment presents less difficulty and danger in children than in adults. In addition to the great improvement in or disappearance of the myxedematous tissue, there has been, as a rule, a marked or even brilliant change in the mental and general physical condition, the child seeming to take up development at the point of arrest and growing afresh in body and mind. But it is the rarest exception, if indeed it has ever occurred, for the child to attain mental and bodily vigor equal to that of other children of the same age. In only a few has speech been acquired when it was previously absent. [Clearly, the time to begin the administration of thyroid extract in these cases is at the very earliest possible moment. Then, if long continued, there might be some hope of a real cure, which, so far as we have been able to learn, has not yet been recorded.]

Mercurial Multiple Neuritis.—Cases of pronounced multiple neuritis from the therapeutic use of mercury are rare, but are always possible, as the following 3 cases seen by Spillmann and Étienne[3] in 1 year will show. The first patient, a man of 35, contracted gonorrhea, and received therefor, from a druggist, some tablets and a "vegetable" syrup. At the end of 5 days he began to have symptoms of mercurial poisoning, and 18 days from the beginning of treatment he was found by the authors to present all the symptoms of severe multiple neuritis. Paralysis of all extremities was complete, and intense salivation, stomatitis, gingivitis, and puffy face showed clearly the kind of intoxication. The patient soon began to improve; in 3 weeks could walk a little, and at the end of 4 months was practically well. [It is well to note that in the period of convalescence the knee-jerks were exaggerated, for it is, perhaps, not sufficiently well known that in incipient and convalescent and

[1] Brit. Med. Jour., June 27, 1896.

[2] Pediatrics, May 1, 1896.

[3] Rev. de Méd., Dec. 10, 1895.

mild cases of peripheral neuritis the knee-jerks may be exaggerated.] It should be added that analysis of the tablets and syrup taken by the patient revealed a large proportion of mercury, and this metal was found in the saliva and in the urine even at the time of his discharge. The second case, a man of 25, contracted syphilis, and as soon as the roseola appeared began to take mercury. In 20 days he took 160 pills of protiodid [strength not stated] and made 11 mercurial inunctions. Almost immediately afterward the symptoms of neuritis appeared, apparently aggravated by exposure. At the end of 2 months he could not walk without support, presented marked incoordination, anesthesia, pain, tenderness, atrophy and loss of knee-jerks. After this he began to improve, but for 6 weeks suffered from severe pain and exquisite tenderness in the muscles. Six months later he could only walk about 200 yards, and it was more than a year before recovery was complete. The third case was treated by the authors themselves for active syphilis by means of intramuscular injections of thymol-acetate of mercury. From May 5 to June 9, 6 injections were given without any local disturbance. About the time of the last dose the patient began to complain of weakness, pain, and uncertainty of gait, and in a few days was the victim of well-developed neuritis of moderate severity. In a month he began to improve, and in another month was well. The authors cite 3 similar cases from the literature.

Neurotabes from Diphtheria.—Dejerine[1] reports a new case of typical pseudolocomotor ataxia. The neuritis in this case was caused by diphtheria and was of the purely sensory type. There was no weakness, no atrophy, and no electric change, but anesthesia, marked incoordination, and loss of reflexes. The affection lasted about $3\frac{1}{2}$ months. Dejerine[2] also reports a case of multiple neuritis, apparently alcoholic, peculiar in that the tibialis anticus remained unaffected. This, indeed, was the only thing that threw doubt on the diagnosis, as the author had never known this immunity of the anterior tibial to occur in any but saturnine neuritis—with the exception of one case of indeterminate etiology.

Neuritis following Pneumonia.—Peripheral neuritis of any kind after pneumonia is rare, and a case of bilateral neuritis of the brachial plexus reported by Leszynsky[3] is altogether exceptional, if not entirely unique. The patient, aged 36, was attacked in the third week of pneumonia, the inflammation involving only the upper part of the plexus on either side, and this only to a limited extent. The right circumflex nerve was affected, but almost exclusively in its sensory distribution, and the left posterior thoracic (serratus magnus muscle). [It would seem to us, judging from the distribution, that the nerves became involved by direct extension of the inflammation or infection from the lungs, not from the general blood-state, as is usually the case.]

Multiple Neuritis in Pregnancy and Childbed.—Multiple neuritis in pregnancy is rare, severe if not dangerous, and nearly always accompanied by, if not due to, hyperemesis. Puerperal neuritis is less grave, and ordinarily

[1] Rev. de Méd., 1895, No. 5. [2] Jour. de Méd. de Paris, 1896, p. 138.
[3] N. Y. Med. Jour., Apr. 11, 1896.

due to infection. Vinay[1] reports a case that is, to a certain degree, a transition form between the two. During the first months of pregnancy the patient lost a great deal of blood, and during the last months suffered from hyperemesis, so that she came to confinement in a cachectic state. During the last 2 months of pregnancy she complained of paresthesia of the extremities and of pains and weakness in the legs. On the third day after delivery she had a chill, with fever that lasted only 48 hours, but on the fourth day she noticed that there was marked loss of power in all the extremities. This rapidly increased until she was almost completely paralyzed. About 6 weeks after confinement she began to improve, and 4 months from that date had fully recovered.

Alcoholic Neuritis and Tuberculosis.—Kelynack in 3 years examined postmortem 8 cases of alcoholic multiple neuritis, and found in 7 of them active tuberculosis. He thinks that a consideration of these cases seems to warrant the following conclusions: 1. The subjects of alcoholic paralysis are peculiarly liable to pulmonary tuberculosis. 2. A recognition of this fact is of considerable importance in arriving at an early and complete diagnosis and in forming a reliable prognosis. 3. It is desirable to treat cases of alcoholic paralysis in special hospitals, in country homes, or in healthy private houses, rather than in the almost unavoidably tubercle-contaminated wards of a general hospital. 4. The necessity for immediate removal of all alcohol from these cases and its replacement by nutritious diet. 5. The careful avoidance of causes leading to, and the necessity for early treatment of, all catarrhal conditions of the respiratory passages and congested states of the lungs.

Sharkey,[2] in opening a discussion on **multiple neuritis** before the British Medical Association, very properly called attention to the fact that many cases are wrongly called "neuritis," as the pathologic process is one of degeneration and involves none of the phenomena that belong to inflammation in other parts of the body. For such cases [and in our opinion they constitute the majority of cases grouped under "multiple neuritis"] he proposes the term "peripheral nerve-degeneration," restricting the term "neuritis" to the cases in which the ordinary vascular changes of inflammation are present. There is a third class of cases, generally rapidly fatal, as some cases of Landry's paralysis, in which no anatomic changes are found, and these he would designate "peripheral nerve-intoxication." This conception of the pathology of these cases was generally concurred in by those present. The only dissenting voice was that of Saundby, who was willing to concede that some cases might be purely degenerative, but thought that the ordinary processes of inflammation were generally present. Marinesco of Paris dwelt upon the pathogeny, which is nearly always that of an infection or intoxication. The fact that the terminal filaments are first affected was also considered. Sharkey thought it might be due to their more delicate structure, or because the finer filaments would be more accessible to the circulating poison than would be fibers gathered into a compact bundle, or because, perhaps, the nerve-endings are farthest removed from the trophic center of the fibers, the cells in the cord. Mott called atten-

[1] Lyon méd., Dec. 22, 1895.

[2] Brit. Med. Jour., Feb. 22, 1896.

tion to the theory advocated especially by Marie that the nerve-changes are not primary, but depend upon some change in the nerve-cells from which the fibers spring. In the present state of the technic for examination of nerve-cells he thought it impossible in many cases to prove or disprove either the central or peripheral origin of the changes. In some cases, however, they are certainly due to the direct action of the poison on the terminal filaments. Sharkey and Grainger Stewart both noted the peculiar and unexplained "affinity which certain poisons seem to have for certain nerves." [We consider this an unfortunate, because probably inacurate, way of stating the clinical fact. It were better spoken of as a peculiar vulnerability of certain nerves to certain poisons.] Grainger Stewart spoke of the remarkably good results he had obtained in the treatment of these cases from the hypodermic injection of strychnin after the acute stage has passed. [See *Year-Book* for 1896.]

Neuritis with Spinal-cord Disease.—Petrini[1] describes a case that, so far as we know, is unique in presenting a multiple neuritis complicated by a severe spinal-cord lesion. The patient, a man of 37, a drinker and syphilitic, had a year previously recovered from an attack of multiple neuritis of the pseudotabes type. The final sickness began with pain, paresthesia, and weakness in the legs, gradually increasing in degree and spreading upward, until at the end of a month he was completely paralyzed, with muscular atrophy and reaction of degeneration. The muscles of respiration then became affected, tachycardia appeared, and the patient died about 6 weeks after the onset. The sphincters and pupils remained normal to the last. The microscopic examination showed degeneration and atrophy of all the nerves and muscles examined, and in addition a focus of softening in the cervicodorsal cord. The author does not make it plain whether this softening was hemorrhagic or thrombotic, but thinks it depended on diseased arteries due to syphilis. [Although a doubt remains in the reader's mind whether this focus may not have been a postmortem softening or artefact, it is an undoubted fact that alcohol or syphilis, or a combination of both, may cause at once multiple neuritis and degeneration of the arteries. We have, then, the possibility of an ascending paralysis, such as this was, caused by a combination of peripheral neuritis and acute cord-disease due to vitiated arteries.] Dejerine and Sottas[2] report a case of multiple neuritis with cell-changes in the cord. The patient presented all the symptoms of severe neuritis, gradually improved to a considerable extent, but never fully recovered. Seven years after the beginning of the trouble he died of tuberculosis, and the microscopic examination showed not only degeneration of the peripheral nerves and anterior roots, but also distinct changes in the cells of the anterior horns; which changes, they reason from the symptoms and histologic changes, were secondary to the neuritis, and not primary. Ballet and Dutil[3] have reported a similar case. The peripheral nerves were

[1] Jour. de Méd. de Paris, Sept. 8, 1895. [2] Abst. in Internat. Med. Mag., May, 1896.
[3] Progrès méd., May 16, 1896.

markedly degenerated, the anterior roots only slightly so, but there were distinct changes in the ganglion-cells of the anterior horns.

Neuritis from Bicycle-riding.—Dr. Destot[1] after a long ride on a wheel was attacked by a severe neuritis of the ulnar nerve, and he ascribed it to the pressure of the handle on the nerve at the root of the hand. If the handle be so constructed as to be grasped at a right angle with the full hand, the pad of flexor tendons and the fleshy part of the palm receive the pressure, and no injury can result; but if the handle must be grasped at an angle, pressure is exerted near the wrist, where the nerves are comparatively superficial, and considerable damage may be done.

Sensory Dissociation in Peripheral Disease.—Dissociation of sensation, for some time thought to be pathognomonic of syringomyelia (q. v.), has been found to be occasionally present in peripheral neuritis, tabes, hysteria, and other diseases. Barker[2] in an interesting study of "elective sensory paralysis" describes the reverse of the more usual sensory dissociation. In his own person pressure of a so-called cervical rib upon part of the brachial plexus caused anesthesia for touch, pressure, warmth and cold in the distribution of the cutaneus internus and antibrachius medialis, while sensation for pain was nearly or quite normal.

Nocturnal Incontinence.—Mendelssohn[3] in a long paper on this subject comes to the conclusion that the most generally successful treatment is a combination of three means—a supper without fluids, elevation of the foot of the bed [which is often of very signal service], and tincture of rhus aromatica, from 10 to 15 drops t. i. d., which, he says, seems to have a specific action in this trouble. It goes without saying that the general health of the child and any local affections of the genito-urinary system are to receive prompt attention. Prendergast[4] warmly advocates the cold douche or shower-bath at bedtime. He systematically used it on 80 "bed-wetters" (all boys) in an orphan asylum, and at the end of a few months all but 5 were considered as cured, and the 5 were all improved. He says, further: "During the whole course of treatment not a boy was placed on special diet; they ate whatever was served at meals, drank tea at supper, and had as much water as they wished. Not a drug of any kind was given, and not the slightest attention was paid to any peripheral causes, such as a long foreskin, tight prepuce, condition of the urine, etc., so that the test was a thorough one. One of the boys had been circumcised a year previous to the cold-water treatment without benefit, but was cured in 2 weeks by the douching. One very nervous lad was completely cured with 1 bath, probably owing to the shock and the profound mental impression. One of the cases cured was that of a feeble-minded boy of 11; he was mentally so deficient that it had been impossible to teach him the alphabet after 4 years' attendance at school, so that mental impression does not wholly account for the cure. The method employed in treating the cases was as follows: The boy was stripped and placed standing in an empty bath-tub; a basin, or a vessel

[1] Prov. méd., June 20, 1896.
[2] Jour. of Exper. Med., Apr., 1896.
[3] Berl. klin. Woch., Nov. 25 and Dec. 9, 1895.
[4] N. Y. Med. Jour., July 11, 1896.

with a spout to it like a watering-can, was filled with cold water and poured over the shoulders and down the back of the subject. In the nervous, delicate children one dash of water was sufficient for an application; in the sluggish, phlegmatic lads the dose might be repeated. The boy was immediately rubbed down, dressed in his night-clothes, and put to bed. From a hygienic point of view the cold water has proved an excellent tonic; not 1 of the 80 boys has had a 'cold' the past winter. A number of the boys treated suffered from incontinence of urine during the day, but all have been cured. Occasionally we have a backslider whose spinal center takes a 'nap,' but it is at once put on guard by a douche or two. The ages of the boys ranged from 6 to 12 years, and we have 485 in the institution. Since starting this article I have learned an important point in carrying out this treatment: it is, that sponging the back with cold water does not have the same effect as the douching. A private patient brought her boy to me for treatment for this condition. I ordered the cold douching, but the mother, from false motives of sympathy for the child, objected, and compromised by sponging the spine with cold water. She informed me 2 weeks afterward that cold sponging had had no effect, but that 6 cold douchings with a fountain syringe had cured the boy; this was a month ago, and the child has not relapsed yet. From this I would judge that the shock of the cold water is one of the important elements in the cure of the condition." [The author's theories as to the *modus operandi* of the treatment in the different kinds of cases are interesting, but not always convincing. The fact remains, however, that his results are extremely good, and the method certainly deserves an extensive trial.]

Raynaud's Disease in Children.—It is commonly supposed and generally taught that Raynaud's disease is rare under the age of 18, but Maugue,[1] having collected 171 cases of this disease, finds the ages as follows: 6 under 2 years, 5 in the third year, 35 between 4 and 18, 33 between 18 and 20, 46 between 30 and 43, and 46 between 43 and 77. He reports 3 original cases occurring during the first year of life, and 3 in infants 2 years old. The proportion, then, of cases to any one year is fully as high in the first years of life as it is later. In this connection we might mention a case recently reported by Batton[2] in a child of 3. The case seems to have been typical in every respect, the disease affecting the hands and feet, both ears, and the tip of the nose; there was no gangrene, and rapid improvement followed the administration of nitroglycerin.

Insomnia.—Rosenbach[3] proposes a novel device to protect nervous patients from noises of the house or street that prevent them from sleeping. A piece of cotton wadding about 6 by 3 cm. and 1 cm. or less in thickness is spread with a coating of vaseline and rolled into a tampon, the ends being slightly pinched in the rolling. This is then inserted into the auditory meatus to a depth of 2 or $2\frac{1}{2}$ cm.; the protruding end is flattened out in the hollow of the ear and covered with a thin layer of cotton, which readily adheres to the

[1] Jour. de Méd. et de Chir. prat., Sept. 25, 1895. [2] Phila. Polyclinic, Mar. 30, 1895.
[3] Münch. med. Woch., Aug. 13, 1895.

vaselin. This plug will exclude all but the loudest noises. On removing it the meatus is lightly wiped out.

Homolateral or Collateral (Uncrossed) Hemiplegia.—Pineles[1] records a case of cerebral apoplexy with right-sided hemiplegia, in which the lesion found was a large meningeal hemorrhage of the right convexity. As microscopic examination showed good pyramidal decussation, the author attempts to explain the condition by supposing that the lesion, by pressure and indirectly by general edema of the brain, caused really a paralysis of all four extremities, but that the local irritation of the right motor cortex by the clot caused the muscular tonus and apparently voluntary movements observed on the left side. [The explanation seems to us scarcely adequate, as some of the movements (for example, an attempt to take a glass of water from the nurse) were too palpably the result of volition.]

Lederhose[2] reports a similar case due to traumatism in which trephining was done on the side opposite the hemiplegia, and the postmortem revealed a large subdural clot on the same side as the paralysis. He concludes that—1. In all kinds of brain-lesions with following hemiplegia this may be exceptionally collateral or uncrossed. 2. Dilatation of the pupils or unilateral choked disk on the hemiplegic side may lead to the diagnosis of a collateral brain-lesion or hemorrhage.

Arteriosclerosis of the Central Nervous System.—["Arteriosclerosis, the most frequent vascular disease of the central nervous system," certainly merits the careful, we would fain say the more careful, attention of practical physicians. It gives rise to a great multiplicity of symptoms of all degrees of severity, and these symptoms may be so grouped as to closely simulate other functional and organic disease of the nervous system.] Jacobsohn[3] divides the cases simply into mild and severe, although it is impossible to draw a sharp line of distinction, especially as the symptoms are not always proportionate to to the vessel-change. The graver symptoms are caused either by the plugging of a narrowed vessel with a thrombus or embolus or by hemorrhage from a dilated and fragile vessel. To these might be added symptoms due to the pressure of an aneurysm on the surrounding tissue. Thrombosis is the most frequent lesion, but is often combined with hemorrhage or aneurysm. So far as the nerve-tissue is concerned, the result is practically the same, be the lesion hemorrhage, thrombosis, or embolism. There is a destruction of the nerve-elements resulting in a cicatrix or a cyst. On microscopic examination Jacobsohn finds a great number of minute atrophic areas immediately surrounding the smaller and smallest arterial twigs, which have become narrowed in caliber or quite occluded. [This finding we consider important, as it would explain many of the more general psychic and somatic symptoms of arteriosclerosis—symptoms that frequently seem to point to a functional neurosis rather than to organic brain-disease.]

[3] Arch. f. Psych. u. Nerv., Bd. xxviii. H. 3.

It is a peculiar and, as yet, unexplained fact that although no arteries of the brain or cord are exempt from arteriosclerosis, the process has a special predilection for the vessels of the basal ganglia, pons Varolii, and medulla oblongata. Why miliary aneurysms develop in the former location and other forms of arterial degeneration in the latter, why hemorrhage is more frequent in the vicinity of the internal capsule and thrombosis in the pons and medulla, is still an unsolved riddle. [Although it is probably true that the intravascular pressure is greater in these two sets of vessels than elsewhere in the brain, we are not ready to assume, with the author, that this would conduce to a plugging of the arteries as well as to their dilatation and rupture.]

A valuable part of the paper is that devoted to so-called **acute bulbar** (glossolabiolaryngeal) **paralysis,** which, the author proceeds to show, does not belong to the same category as the chronic affection of the same name, but is simply the result of arteriosclerosis, often syphilitic, of bulbar and pontine vessels. Clinically, it is atypical or irregular in the grouping of symptoms, because of the invasion by this same vascular change of neighboring or distant parts of the central nervous system. He proposes, therefore, to call the disease "multiple softening," and in support of the proposition reports a carefully studied case that was indeed atypical in symptom-complex and course, in which arteriosclerosis was the sole cause, and in which the exact microscopic examination showed widely disseminated lesions, various in degree, but all of the nature of softening. [There is no doubt that the author's thesis is entirely valid as regards his own and many other cases, but whether all cases heretofore known as acute bulbar paralysis fall within the same category must be determined by more extended experience. We think such will not be found to be the case.] In this category belongs a case very carefully studied and reported by Van Oordt:[1] A man of 73 was suddenly stricken with weakness of the left side and inability to swallow. The soft palate was paralyzed. He died 2½ months later, and the postmortem examination revealed a large unilateral focus of thrombotic softening in the medulla oblongata. The paper gives extensive references to the literature, as does also that of Wallenberg,[2] who reports a similar case, which, however, exhibited extensive and peculiar disturbances of sensation. There had been no autopsy in this case, and the diagnosis lay between thrombosis and embolism. Wallenberg thought the latter the more probable. Thérèse[3] gives an excellent resume of the subject of thrombosis of the vessels of the medulla oblongata, although reporting no original cases.

Hemiplegia in Typhoid Fever.—Osler[4] in reporting 2 cases of hemiplegia occurring in the course of typhoid fever gives the following classification of paralyses that occur during and after the specific fevers:

[1] Deutsch. Zeit. f. Nerv., 1896, Bd. viii. H. 3 and 4.
[2] Arch. f. Psych., Bd. xxvii. H. 2.
[3] L'Union méd., 1896.
[4] Jour. Nerv. and Ment. Dis., May, 1896.

Symptoms.	*Lesion.*
Hemiplegia. . .	Thrombosis of veins of meninges. Thrombosis and embolism of cerebral arteries. Hemorrhage. Meningoencephalitis.
Paraplegia. . .	Myelitis. Neuritis.
Diplegia. . . .	Neuritis.
Monoplegia. . .	Poliomyelitis. Neuritis.
Local paralyses.	Neuritis. (Toxic. Pressure.) Myositis.

The cases of neuritis greatly outnumber all other forms of paralysis in typhoid. The 2 cases of hemiplegia reported are the only instances that have come under the author's observation in a large experience with typhoid. The first patient was a girl of 7. The hemiplegia came on suddenly in the tenth week of typhoid, and the onset was attended with convulsions limited to the paralyzed right side, and unconsciousness. The face was involved, and there was aphasia for 7 weeks. The second case was that of a man aged 25. The hemiplegia suddenly appeared in the second week of the fever, unattended by convulsions. There was gradual improvement, but 8 months after the attack the hemiplegia was still marked—dragging of the foot, and the hand useless. Osler does not attempt a pathological diagnosis in his cases, but thinks the lesion in these cases is generally thrombosis. In this connection he also reports a fatal case of thrombosis of the cortical arteries in the course of typhoid. The patient, a man of 22, on the ninth day of the fever was suddenly attacked by a distressing feeling in the head, which was followed by a short, sharp clonic convulsion, with conjugate deviation of the eyes, rotation of the head, and unconsciousness. Further convulsions followed, and the patient died 8 hours after the onset. The autopsy showed thrombosis of the ascending parietal and parietotemporal branches of the middle cerebral artery.

Probably the only additional case in recent literature is that of Haynes, reported in the Bulletin of Johns Hopkins Hospital:[1] A man of 30 had a severe attack of typhoid fever, lasting 21 days, during the course of which the temperature rose as high as 105° F. On the 14th day of his illness it was noticed that he moved the left extremities less frequently and perfectly than the right. There were no spasms or convulsions of any kind. Improvement was very slow, but at the end of a year the leg had regained almost perfect function, although the arm was still greatly disabled. As the lesion was presumably cerebral, and as atrophy from cerebral lesion is rare, it is worthy of note that the muscles of the affected arm were markedly atrophic and showed diminished electric response.

[1] Jour. Amer. Med. Assoc., Dec. 12, 1896.

A New Type of Crossed Hemiplegia.—[There are 2 classical forms of crossed hemiplegia or crossed paralysis—that caused by a one-sided lesion in the lower part of the pons, in which the face is paralyzed on the side of the lesion and the extremities on the opposite side, and that due to a lesion of one crus cerebri, causing oculomotor paralysis on the same side and hemiplegia on the other.] Anna Goukovski[1] describes a third type, in which the tongue (hypoglossus) is paralyzed on one side and the extremities on the other. The illustrative case was a man of 60, who had an obliterating endarteritis, causing a focus of softening in one side of the medulla oblongata, just above the pyramidal crossing, which involved the motor fibres for the extremities of the opposite side and the root-fibers of the hypoglossal nerve for the same side. Raymond[2] also describes a peculiar case of crossed paralysis. The patient, a syphilitic woman of 39, presented paralysis of the extremities and lower part of the face on one side and of the external rectus of the eye (abducens nerve) on the other. On this side, too, the motor oculi communis was somewhat affected, as shown by slight dilatation of the pupil and its sluggish reaction to light and accommodation. The author makes a diagnosis of a basilar lesion which compressed the sixth nerve, involved to a slight extent the third, and affected the upper part of one side of the pons sufficiently to interfere with the pyramidal tract for the face and extremities.

Meningitis.—Well-authenticated cases of cerebrospinal meningitis in subjects as young as 6 days are rare. Roth[3] reports such a case. The course of the disease was sufficiently typical, but very rapid, lasting only 2 days. The child was at first restless, starting and crying out frequently, and had a temperature of 104.2° F. After the inception the temperature was lower, but there were frequent convulsions and transient attacks of cyanosis. Death immediately followed a severe convulsion. The autopsy showed the usual lesions of cerebrospinal meningitis, and bacteriologic examination discovered large micrococci in pairs or chains of 4 (pneumococcus). The mercury-treatment of cerebrospinal meningitis is not new, but Consalvi[4] reports unusually good results in 9 cases occurring in an epidemic of grip. Only 1 case, that of a girl aged 7, proved fatal, and in this case there was temporarily an improvement following the injections. The dose varied from $\frac{1}{13}$ to $\frac{1}{7}$ gr. of the bichlorid, according to the age of the patient, administered hypodermically once in 24 hours in the beginning and later once in 48 hours. The oldest patient treated was 19 years, the youngest 14 months. Most of the symptoms were relieved after the first 2 or 3 injections, though muscular rigidity persisted in some cases until after the seventh or eighth injection. In 1 patient an acute mercurial stomatitis developed after the tenth injection, and in another (both girls) a bloody diarrhea of short duration seemed to be the result of the remedy. Other therapeutic measures employed were leeches, ice, calomel in purgative doses, and bromid or morphin to quiet the patient when

[4] La Sem. méd., Jan. 15, 1896; Jour. of Nerv. and Ment. Dis., May, 1896.

necessary, with potassium iodid during convalescence. Smith[1] also reports very uniform success with the remedy. He begins with $\frac{1}{4}$ gr. of mercuric chlorid hypodermically, and then gives $\frac{1}{15}$ gr. every hour until there are symptoms of gastrointestinal irritation. He says that he has not lost a case in the last 10 years, during which time he has pursued this plan of treatment. He cites 7 cases. An early and constant sign of meningitis[2] is said to be a want of harmony in respiratory movement between the chest and abdomen. The chest-movements are almost restricted to the lower chest, and on inspiration the abdomen, instead of rising, as is normal, remains immovable or there is some retraction.

Exophthalmic Goiter.—[The latest and perhaps now the most generally supported theory (for as yet all is theory) regarding the pathology of exophthalmic goiter—Graves' disease, Basedow's disease—is that which considers the disease dependent upon abnormal action, probably over-action, of the thyroid gland. But this theory is far from being entirely satisfactory, and much more information is necessary before it can be unreservedly accepted.] This assertion is supported by the elaborate monograph of Brissaud.[3] He found, however, from the careful microscopic examination of the thyroids from 2 cases of Graves' disease and of 25 thyroids from miscellaneous cases, as well as from a consideration of the literature, that although the glands in exophthalmic goiter showed no changes peculiar to that disease, yet quantitatively the changes were always such as to make "hyperthyroidation" possible. [The results of treatment have not thrown much light upon the nature of the disease. Most cases have been aggravated, or at least not benefited, by thyroid extract, but a few have been improved. The same may be said of the preparations of thymus gland.[4]] Even the results of extirpation or partial extirpation of the gland are rather contradictory, although many cases have been unquestionably benefited by the operation. Starr,[5] an active advocate of the thyroid theory, has made a recent collection of operated cases which makes a very good showing for the operation. [But we are inclined to think that a close scrutiny of the cases would somewhat modify the number of "entirely cured."]

Generally, the first symptom relieved by the operation is the tachycardia; the nervousness, sweating, paresthesia, etc. improve later, and the exophthalmos is the last to yield. Improvement after operation, therefore, may be expected to be gradual and progressive. Regarding medicinal treatment Starr says: "I desire to mention one remedy which in several cases has seemed to me to be of great service—namely, the glycerophosphate of sodium, in 20-gr. doses, 3 or 4 times a day. This was first used by Trachewsky in Kocher's clinic, and was found to have the effect of diminishing the size of enlarged thyroid glands. It has also been successful in the hands of Chibret. Under

treatment by this drug alone a patient in the Presbyterian Hospital was markedly benefited within 3 weeks. A second patient, to whom various forms of treatment were given by me for 1½ years, appreciated within 2 weeks the fact that this remedy had been of more decided benefit in every direction than any other which had been used in the previous period."

The present confusion of the subject is well illustrated by the discussion of Dr. Starr's paper.[1] In this 13 physicians took part, and scarcely 2 were of the same opinion regarding either the pathology or treatment.

Steinlechner[2] records a case of Graves' disease complicated with tetany [which is confusing if we admit the thyroid theory of the former disease, as the latter is often caused by removal of this gland].

Hösslin[3] in an extensive paper on exophthalmic goiter lays particular stress upon two therapeutic measures. For the distressing attacks of tachycardia to which many of these patients are subject he has found nothing equal to clysters of some emulcent containing 20 to 30 drops of tincture of opium. [The drug is ordinarily not well borne when given by the mouth.] The other important point in the treatment is to put the patients on an exclusively vegetable diet.

Tetany.—Marschner[4] reports 5 cases in adults from the clinic of von Jaksch, all of which were seen within 5 months. The first case is noteworthy from the presence of choked disks. "The disk on either side was indistinctly defined, somewhat reddened, and there was venous congestion of the retina; these changes were less pronounced on the left side than on the right." With improvement in the tetany the papillitis gradually grew less marked, but had not entirely disappeared when the patient was discharged. The second patient had a moderate goiter, and was put on thyroid extract for 2 weeks, which seemed to reduce the size of the gland somewhat, but had no influence on the symptoms of tetany. In the third case the thyroid gland seemed to be normal, but the patient was given thyroid tablets for a period of 2 weeks. They apparently had no effect either upon the course of the disease or the size of the thyroid. The fourth patient was treated with Leichtenstern's tablets of thyreoidin during the time of observation, three weeks. They caused some decrease in the size of the previously slightly enlarged thyroid gland, but are said to have had no effect upon the tetany. [As the patient improved, and when discharged was free from attacks and Trousseau's symptom was no longer obtainable, it would seem to us difficult to substantiate this latter assertion.] The fifth patient was suffering from carcinoma of the stomach with metastatic growths in the omentum, and had her first and only spasm of tetany following the removal of 7½ liters of fluid from the peritoneal cavity. In all of these cases except the fifth the faradic reaction of nerves and muscles was found to be exaggerated, contrary to the experience of most observers, who have found this exaltation of electric excitability limited to the galvanic current.

Thomson[5] treated a rachitic baby 15 months old suffering from tetany by

[1] Jour. of Nerv. and Ment. Dis., June, 1896. [2] Wien. klin. Woch., 1896, No. 1.
[3] Münch. med. Woch., No. 2, 1896. [4] Deutsch. Arch. f. klin. Med., Mar. 26, 1896.
[5] Arch. of Pediat., 1896, xiii. No. 3.

the administration of thyroid extract. The result was negative, and antirachitic treatment was substituted. The results of this were also unsatisfactory, although in most cases such treatment is successful. The author thinks thyroid should be used with extra care in patients having a tendency to laryngismus. Bonome and Cervesato[1] report 2 cases in infants of 1 and 2 years respectively. One child had gastroenteritis and rachitis, but the other showed no cause for the affection. [The authors consider their findings in the spinal cord very important, but from the reading of the report we would judge them to be of purely artificial origin, probably caused by careless handling of the cord in removing it or subsequently.] Godart-Danhieux[2] reports a case of tetany in an adult which was of undoubted gastric origin. The patient had been suffering from enormous dilatation of the stomach, with all its attending evils, for some time, and improved and relapsed a number of times. He was finally, when in a state of exhaustion and emaciation, attacked with very severe and refractory tetany, which proved fatal. The author remarks that scarcely 30 cases of gastric tetany have been published. [This would certainly exclude the infantile cases, and, we think, would not cover those in adults.]

Levy-Dorn[3] reports a typical and fully-developed case treated with tablets of thyreoidin. The patient was a woman of 23. After 3 days of treatment there was distinct improvement, and the spasms ceased after the sixth day, but returned at the time of menstruation, 14 days later. From that time there had been no recurrence up to the time of report, 4½ months. Only 17 tablets were given in all. Krauss[4] reports 5 cases of infantile tetany, all of which occurred in the practice of a physician in Buffalo within a period of 3 months—a most exceptional record for this country. The children were from 6 to 18 months old, and in every case the child was suffering from gastrointestinal trouble or bronchitis, or both. The disease lasted from 6 days to 3 weeks. One patient died 4 weeks later of acute meningitis. Sarbo[5] reports 3 cases, 2 of which were of particular interest, principally because the patients were a mother and her 3-year-old daughter. The third patient was a shoemaker, 17 years old, whose symptoms were sufficiently characteristic, although Trousseau's sign could not be elicited. It is particularly noted that in the triceps there was myotonic electric reaction; that is, a persistence of the contraction after cessation of the electric stimulus. This symptom is almost confined to Thomson's disease, and the author found no record of its occurrence in tetany. From an extensive review of the symptomatology and known causes of tetany Sarbo concludes that the cases all have only one thing in common, and that is a condition of impaired nutrition. The action of all toxic agents and infectious processes is alike in that it impairs the structure, and hence function, of nerve-cells and fibers, but more especially of the former. He then proceeds to show that tetany must be a central disease, an affection of the cells of the central nervous system, with possibly secondary involvement of the peripheral nerves.

Tetanus.—[We gave last year a rather extended report of cases of tetanus treated by the injection of tetanus-antitoxin, which, on the whole, gave a rather favorable impression of this method.] Kneass[1] in an excellent resume of the subject draws conclusions less favorable. He has collected from the literature 68 cases thus treated, of which 61 are available for statistical purposes, and these give a mortality only slightly less than that prevailing under older methods. [It is known that the shorter the period of incubation the greater the mortality. Cases developed within a week rarely recover, and when the period of incubation is more than 2 weeks they rarely die.] The author says: "When we remember the experimental proof that the sooner after inoculation the antitoxic serum is injected the more likelihood there is of some beneficial result, we should expect, if there be any such effect, to find it among those cases in which the treatment was earliest begun. A glance at the table will show that this is not the case. Of the 16 fatal cases whose period of incubation ranged from 6 to 14 days, 14 had the treatment begun during the first 4 days, and of the 25 in which the serum was injected before the fifth day, 14 were fatal. Among the 68 cases but 22 are reported as causing an immediate improvement in the character of the symptoms, and in many of these the injections were begun so late in the course of the disease that one hesitates to ascribe this improvement to anything but a coincidence. This agrees with many of the authorities. Burger says that 'without rejecting the injections of antitoxic serum in the treatment of tetanus, we can have but the most limited confidence in its curative efficacy.' Roux has said that he has never seen the serum have the least effect upon the course of the disease."

Tirard[2] records a case of recovery. A girl of 4, daughter of a butcher and accustomed to run about the stables in her bare feet, began to be ill about 2 weeks after receiving a cut on the foot. After 3 days of general malaise severe convulsions began, and continued in spite of large doses of chloral. Antitoxin was first given more than 3 days after the first convulsion and when the child was in bad condition, there being general rigidity, trismus, risus sardonicus, frequent general convulsions, and more frequent "starts." Six injections of 10 gr. each were given in 3 days before there was material improvement, although some amelioration was noted after the third dose. After this the progress toward recovery was continuous, but slow, it being a month before it was complete. Marson[3] reports the case of a man aged 28 who suffered a compound fracture of the thumb, and 10 days later developed a rigidity of the masseters. He was treated for 6 days with physostigmin, chloral, and bromid, the stiffness increasing slightly in extent and severity. On the sixth day he had a mild convulsion, and was given an injection of 34 gr. of antitoxin, which was repeated in 8 hours. There was some immediate improvement, and the remedy was given during the next 4 days in diminishing doses. Although the convulsions ceased, the temperature steadily rose during the administration of the antitoxin, and continued after it was withdrawn,

[1] Jour. Am. Med. Assoc., July 18, 1896. [2] Lancet, Nov. 2, 1895.
[3] Ibid., Aug. 10, 1895.

reaching 104.2° F., and the patient died, apparently of heart-failure, in an unconscious state following delirium. No autopsy. The author collected 38 cases of tetanus treated with antitoxin, with 25 recoveries. Of 22 in which particulars were given, 17 recovered, and of these 9 were designated as "severe," with 5 recoveries, and 13 as "mild," with 12 recoveries. [It will be seen that these statistics give a much more favorable view than those of Kneass.] Hartley[1] reports the case of a man of 44 injured while shoeing a horse. The first symptoms of tetanus appeared 13 days later, and after 2½ days, chloral having no effect, he was given 1 g. of antitoxin. This dose was repeated daily or twice daily for several days, and chloral was given at the same time. The antitoxin controlled the convulsions and local spasm much better than did the chloral, but was more depressing, and the latter drug induced sleep fully as well as or better than the former. The best result seemed to be attained by the administration of both—the antitoxin to calm the muscular spasm and the chloral as a hypnotic. Marked improvement did not occur before the twelfth day of the disease; he was sent home 3 weeks after the onset, and the injured arm was somewhat rigid for 5 weeks more. In this case, as in many others, the antitoxin produced an urticarial rash. The injections were painful and caused local swelling and inflammation.

"In summing up Cowling's report on tetanus, Yandell says: 'Recoveries from traumatic tetanus have been usually in cases in which the disease occurs subsequent to 9 days after the injury. When the symptoms last 14 days recovery is the rule, apparently independent of treatment. The true test of a remedy is its influence on the history of the disease. Does it cure cases in which the disease has set in previous to the ninth day? Does it fail in cases whose duration exceeds 14 days? No agent tried by these tests has yet established its claim as a true remedy for tetanus.' In how many cases has tetanus antitoxin been tried when the symptoms have come on at an early date after the injury, and what have been the results?"

Timmermann[2] reports a case of recovery in which the period of incubation was 17 days. Physostigmin, morphin, and chloral seemed to control the spasm at first, but after a few days respiration was so impeded as to render death apparently imminent, and antitoxin was given. Improvement was not immediate, but gradual, more than a week elapsing before the spasms ceased. Withington[3] reports a case following abortion. It recovered under antitoxin and other remedies, but was atypical in many respects, and the diagnosis cannot be unquestioned. Smith[4] alludes to 4 cases of tetanus neonatorum treated with antitoxin, of which 1 recovered. Walko[5] reports a case coming on 9 days after confinement. Injections were begun on the fourth day of the disease, 0.2 g. being given every 5 hours. The patient died on the eighth day. Grayson[6] reports a case of moderate severity in a child of 6 who was wounded in the foot by a nail. The period of incubation was 7 or 8 days and

[1] Lancet, Dec. 7, 1895.

[6] Pittsburg Med. Rev., Oct., 1895.

the onset gradual. After 12 days antitoxin was given, as the patient had grown worse on bromid and chloral, with almost immediate improvement. One dose a day, 5 to 10 c.c., for 4 or 5 days was administered, and convalescence was uninterrupted except by a papular eruption. Trevelyan [1] reports a very severe case of cephalic (head) tetanus treated by antitoxin and ending fatally. The period of incubation was 12 days; treatment was begun $1\frac{1}{2}$ days after the onset, and the patient died on the sixth day, the antitoxin apparently having had no effect. Tracey's case [2] also apparently began as head-tetanus, but rapidly became general. The period of incubation was supposed to be 12 days. The first 2 days there was no treatment; then for 5 days it was restricted to bromid and morphin, at the end of which time antitoxin was begun, as the patient had grown worse and convulsions occurred every few hours. After the first dose the spasms were distinctly more frequent and severe, and after the second, 12 hours later, they were still more frequent and were accompanied by delirium. After this there was gradual improvement, antitoxin and morphin both being employed, the former seeming to have more effect than the latter. [Antitoxin was given in this case for more than 2 weeks, and, altogether, the author thinks it was of decided utility. The account of the case as given by him is not very convincing on this point.] The cases of Macartney [3] are somewhat unusual, and in the absence of urinary examination the diagnosis might be questioned. A woman of 50, 8 days after the removal of an epithelial growth, experienced some stiffness about the jaws. This very gradually grew worse, and a week later she began to have spasms with opisthotonos. They were not very severe, but came on (after about 12 hours) every 10 to 15 minutes. The minimum dose of antitoxin was then injected, but it had no effect on the spasms, and the patient suddenly died 1 hour later. The second case was that of a boy of $5\frac{1}{2}$ years who developed the first symptoms 7 days after a crush of the foot. The onset was sudden and violent, epileptiform in character, and similar fits occurred several times in the next 12 hours. The existing slough was then freely cut away and one-fifth the adult dose of antitoxin injected. The convulsions continued unabated, and about 4 hours after the first a second dose was administered. This seemed to have no effect whatever, and the patient expired 4 hours later. The author alludes to a third case in the practice of a colleague. The period of incubation was 3 or 4 days, and antitoxin was given early, a second dose being given 6 hours after the first. The remedy apparently had no effect, and the patient died a few hours after the second dose. Thursfield [4] reports 2 cases: The first was a man of 50, injured in an epileptic fit, period of incubation 10 days; first treatment (bromid and chloral) 8 days after the onset, antitoxin the next day. The chloral with morphin was continued, and 1 g. of antitoxin injected from twice a day to once in 2 days. Improvement was gradual, and antitoxin was discontinued after the eighth day. He had occasional spasms for 6 days after this, and it was almost a month before he was well. The second patient was a gardener of 18

[4] Birmingh. Med. Rev., Feb., 1896.

years, period of incubation about 17 days, onset gradual, progress slow; antitoxin first given on the seventh day, when there were well-marked spasms with opisthotonos. In 2 days 3 injections of 1 g. each were given, but the patient grew steadily worse, and died 6 hours after the last dose. [In reading the account of these cases we receive the impression that the antitoxin neither hastened recovery in the first nor retarded death in the second.]

Swindells[1] reports 2 cases of recovery, the only drug given being chloral hydrate in repeated doses. One was a case of chronic tetanus, and the other a mild case of the idiopathic form. Proegler[2] also reports a mild case that ended in recovery. The patient was 2 years old, the period of incubation 2 weeks, and the treatment 5-gr. doses of chloralamid every 3 to 4 hours, given by the rectum. Lawrenson[3] reports a fatal case in which the entrance of infection seems to have been through a chilblain. The patient had been sick for 5 days when first seen, and died the next day. Treatment was chloral, 10 gr. every 4 hours.

Grinnell[4] reports a successful case treated with veratrum viride and gelsemium. The patient, a boy of 6, cut his foot on a piece of glass, and showed the first symptoms of tetanus 9 days later. Two days after that he began to have convulsions. The cicatrix was scraped, the site scarified and disinfected, and bromid given. As there was no improvement after 4 hours, Norwood's tincture was administered, at first 1 drop, later 2 drops, every hour. As this did not prevent the repetition of the spasms, fluid extract of gelsemium was added in like doses. On the third day of this treatment the dose was increased to 3 drops of each every hour, which seemed to control the spasms. These doses were continued for 48 hours, and only once caused vomiting. When complete relaxation had been obtained the amount of the drugs given was gradually diminished for 8 days, when treatment was discontinued. Ammonium bromid was given throughout the period of active treatment in doses of from 3 to 4 gr. every 2 hours.

The New York City Health Department now furnishes the antitoxic serum.

Acromegaly.—[On this subject there is but little to add to the matter contained in the *Year-Book* for 1896. Cases continue to be reported with a frequency that is astonishing, considering that the disease was not recognized until recently.] Dallemange[5] reports 3 cases with autopsy. In all there were changes in the pituitary body, and in 2 of them in the thyroid gland also. [Although changes in the pituitary body are so frequent in acromegaly, the relation of such changes to the disease is still a matter of doubt. Some writers, as Marie, who first described the affection, think that disease of this body causes acromegaly, as disappearance of the thyroid causes myxedema, while others, among them Dallemange, think the changes in the pituitary body are secondary to the general nutritive disturbance of the disease.] This latter opinion is shared by Sanger Brown,[6] who reports a typical case, with

[6] N. Am. Pract., Sept., 1895.

symptoms strongly indicative of enlargement of the pituitary body. Worcester[1] reports a case interesting in the combination of myxedema and acromegaly: A woman of 70 was admitted to the asylum apparently suffering with senile dementia. There was well-marked myxedema, and considerable improvement followed the administration of 5 gr. of desiccated thyroid 3 times a day. After this there was no treatment and no record for a year, when she was found to have the appearance of acromegaly. She gradually grew weaker, and died 6 months later. The autopsy revealed a much enlarged pituitary body, the weight being 58 g. and the longest diameter 4.6 cm. No normal structure was found. The condition of the thyroid was not stated. The results of pituitary feeding throw no light upon the nature of the affection, as they are not at all uniform [as, indeed, we stated last year]. Rolleston[2] reports a sufficiently typical case in a woman of 34, who lost the sight of the

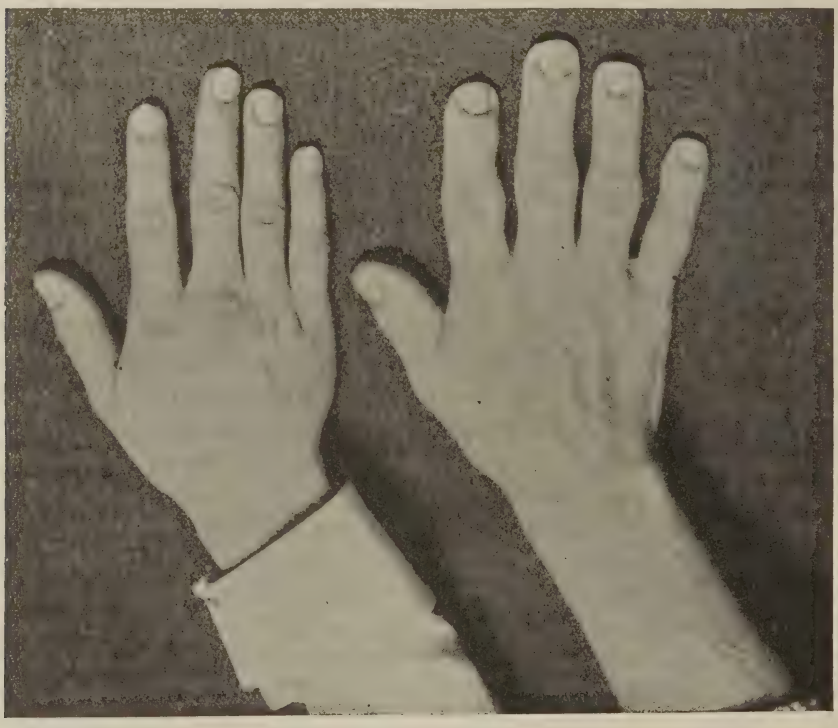

FIG. 133.—Hand of a patient with acromegaly alongside that of a robust woman of the same stature. The broad, spade-like hand of acromegaly is well shown (N. Y. Med. Jour., Jan. 11, 1896).

left eye in less than a year after the onset, and when examined had nasal hemiopia of the other. There were no signs of choked disk, but optic atrophy was present. This pointed strongly to enlargement of the pituitary body, but 5-gr. doses of pituitary extract t. i. d. for a month were of no avail whatever. Ransom has reported negative results of this treatment, while a case under the care of Broadbent[3] seemed to improve. Marinesco[4] has reported

[1] Boston M. and S. Jour. Apr. 23, 1896.
[2] Lancet, Apr. 25, 1896.
[3] Ibid., Mar. 28, 1896.
[4] Mercredi méd., 1895, No. 46.

3 cases, all of them having symptoms indicating pituitary enlargement. The general condition seemed to improve, as did headache and other pains, but the treatment has no effect upon the enlargement. Thayer[1] reports a case of acromegaly and 3 of **pulmonary hypertrophic osteoarthropathy,** with the differential diagnosis and illustrative photographs (see Figs. 133, 134). In the

FIG. 134.—Hand in a case of hypertrophic pulmonary osteoarthropathy beside that of a robust individual of the same stature (N. Y. Med. Jour., Jan. 11, 1896).

latter affection the general nervous disturbances of acromegaly, the eye-symptoms referable to enlargement of the hypophysis, and the overgrowth of the tongue, nose, and chin are absent, although the enlargement of fingers, wrists, and feet may be exceedingly similar. As the patient with acromegaly had a large goiter, she was treated with thyroid extract, but with negative result. Bruns[2] has, among others, reported a case in which thyroid treatment was more effective. A woman of 24 presented nearly all of the signs typical of acromegaly. She was very nervous, excitable, anxious, seldom free from headache, suffered from numerous paresthesiæ and pains in the upper extremities, and all the symptoms were greatly aggravated by exertion. Thyroid extract caused an immediate improvement in all these distressing symptoms, so that she could resume her ordinary pursuits. There was general loss of flesh, but

[1] N. Y. Med. Jour., Jan. 11, 1896. [2] Neurolog. Centralbl., Dec. 15, 1895.

no impression was made on the peculiar enlargements of the disease. After 2 months of active treatment the patient became emaciated, very weak and "chlorotic," and the pulse rose to 120 in the recumbent posture. The glandular treatment was then stopped, quiet enjoined, and iron given, but before the patient had greatly improved in general condition the pains, headache, and paresthesia returned. [The case again shows that thyroid extract is no harmless agent, that it must be used with care, and that its good effects are apt to persist only during its administration.]

Sears[1] reports a very similar case in a woman 45 years of age and of neurotic heredity. She suffered greatly from various paresthesiæ, stiffness of the joints, palpitation, sweating, and mental sluggishness. The physical condition was typical of acromegaly, but there were no eye-symptoms indicating a tumor of the pituitary body. A few symptoms pointed also to myxedema. She was put on general tonics and the dried extract of thyroid gland in gradually increasing doses up to 12 gr. a day. "Three months after her first visit she reported that she was feeling very much better and took more interest in current events. Her memory had improved and she spoke and moved more rapidly. Pain in the hands had greatly diminished, so that she slept well at night, but her joints still felt stiff. Her grasp was firm, and she was able to do her own washing and ironing, even to wringing out the clothes with her hands. The 'puffing' in her ears was gone and the palpitation of the heart better. There was much less puffiness about the eyes and no pitting over the ankles. She had lost over 20 lb. in weight, but felt stronger than for many months. From this time to the present her general condition has remained practically the same or possibly has slightly improved. She has been able to do all her own housework, even to the sewing, and has also gone out on 1 or 2 occasions in the capacity of monthly nurse. Her mental condition is normal, except that she complains that her memory is still somewhat defective. Her weight is still further reduced, so that she now tips the scales at 146 lb., but there has been no change in the measurements of her hands or feet. The longitudinal furrows on her nails are, however, less marked, and her tongue shows a considerable diminution in size. The mucous growths in the nose have disappeared and the nasal passages are unobstructed. During last June she suffered for a time from very severe vertical headaches, and she has had occasional attacks of palpitation and vomiting, which were apparently due to an overdose of thyroid extract, which she has taken almost continuously in daily amounts varying from 3 to 9 gr. The temperature, which was taken only at infrequent intervals, ranged from 98.5° to 99.2°, more commonly the latter."

Last year we presented the thesis of Brissaud and Meige that acromegaly is most intimately related to gigantism. To this Marie emphatically objected, but Brissaud in a second communication[2] advances strong arguments to show that when the abnormal growth begins before the union of the epiphyses the result is gigantism, and when it begins after the period of natural growth the the result is acromegaly. He cites a number of illustrative instances. Among

[1] Boston M. and S. Jour., July 2, 1896. [2] Société méd. des Hôp., May 15, 1896.

these would belong the case of a young giantess reported by Hutchinson,[1] who not only showed some of the signs of acromegaly, but also possessed a greatly enlarged pituitary body, as was shown by autopsy.

Figures 135, 136 represent a case of acromegaly observed by Dr. H. H. Vinke of St. Charles, Mo. The illustrations are of particular value in showing the remarkable changes that have occurred between the ages of 28 and 51 years, and as illustrating the extreme deformities of the disease.

Asthenic Bulbar Paralysis.—[Time and again cases of bulbar paralysis have been reported with negative postmortem findings, also clinical cases closely simulating bulbar paralysis, but apparently not due to organic disease. In the *Year-Book* for 1896 we reported on what Jolly called myasthenia gravis pseudo-paralytica in which bulbar symptoms are pronounced.] Strümpell[2] now adds a typical well-observed case with autopsy, and proposes the above name. The paralysis involved especially the tongue, lips, and pharynx, but the eyes and extremities were to a certain degree affected. There was no atrophy, nor any change in electric reactions, even in almost completely paralyzed parts, which would distinguish it at once from a true bulbar paralysis, Moreover, the reflexes were normal or only slightly exaggerated; but the most striking characteristic was the rapid exhaustion, not only of most of the paretic parts, but also of muscles apparently normal. This striking trait was emphasized by Jolly [see *Year-Book* for 1896, p. 622], but, contrary to Jolly's finding, Strümpell could not demonstrate a like exhaustion after electric stimulus, nor was one group of muscles affected by exertion of another. The patient, a woman of 21, gradually grew weaker, the paralysis more general and complete, choking and dyspneic attacks were added, and she died 13 months

[1] Am. Jour. Med. Sci., Aug., 1895. [2] Deutsch. Zeit. f. Nerv., Bd. viii. H. 1 and 2.

after the beginning of the disease. The careful microscopic examination was entirely negative. [The disease is purely motor, but whether of the central or peripheral nervous system, or of the muscles only, remains for the present undetermined].

Murri[1] reported recently a similar case which had already run a vacillating course of 12 years. His report is interesting in that he found that muscles completely exhausted by the faradic current retained undiminished response to voluntary impulse. He considers the disease to be neuropathic and not myopathic.

Four sufficiently typical cases are reported by Pineles,[2] 2 of which improved and 2 terminated in rapid death from asphyxia. They all presented paresis of muscles supplied by bulbar nerves and the rapid fatigue that is so characteristic. Pineles particularly notes the frequent remissions that may mislead the physician to a diagnosis of hysteria. Bruns[3] in commenting on these cases speaks particularly of the danger of sudden death, and alludes to a case seen by himself in which fatal asphyxia immediately followed the use of an esophageal tube. He cautions also against the use of strong electric currents. The first case of this kind [so far as we know] reported in this country is described by Collins,[4] who with Strümpell prefers to call it asthenic bulbar paralysis. The patient was a woman of 27, whose symptoms had begun 3 years before with sudden ptosis of the left eye and double vision, which trouble passed off in a few months. A couple of years later she experienced for about 8 weeks a similar condition of the right eye. When she came under observation there was a general weakness of the entire body, which was fatigued with extreme ease, but it was particularly the parts concerned in speech, mastication, and deglutition that tired rapidly. A careful examination for organic disease was entirely negative. Under a plan of rest-treatment she rapidly improved, and in 4 months was almost well, when an acute follicular tonsillitis caused a relapse. Under proper treatment she again improved for a few months, when a third and bad relapse suddenly occurred without apparent cause. She had partially recovered from this at the time of the last attack. Without going into details, it is sufficient to say that at no time was there complete paralysis of any muscles, neither was there atrophy, fibrillary twitching, nor any change in electric reaction or in the reflexes, as below noted. The essential features of the case were lack of vigor, with rapid fatigue affecting the entire muscular system, but more especially the tongue, lips, and pharynx. This rapid fatigue also characterized the reflexes and electric response. They were not strong, but otherwise normal, but after being elicited a few times rapidly diminished, and then disappeared until after a period of repose. The special senses, especially sight and hearing, also showed the same lack of endurance. The treatment is rest and the prognosis grave, although cases have been known to recover.

Since the foregoing was written 2 additional cases have been contributed to

[4] Internat. Med. Mag., Apr., 1896.

the literature by Kojewnikoff.[1] At least he describes them under the above title, although it is far from certain that the second one belongs in this rubric. As between various nosological groups individual cases are found that seem to be transition forms, so this patient of Kojewnikoff seemingly presents the characteristics of an incomplete case of progressive glossolabiolaryngeal paralysis with the principal symptoms of asthenic bulbar paralysis added. That is, it apparently unites the pathology of the two classes of cases, and the conclusion might be drawn that the process in asthenic bulbar paralysis differs from that of chronic bulbar paralysis only in being less in degree and less definitely located.

Disturbance of Speech from Anemia.—In connection with the foregoing should be noticed the cases recently described by Hallervorden[2] [although this author himself seems to have overlooked their clinical resemblance]. He observed 3 well-marked and strikingly similar cases of a peculiar speech-anomaly caused by the acute anemia of severe hemorrhage. The trouble consisted in a combination of alalia and aphasia; that is, the patient in the first place could not articulate distinctly, speaking with the thick, dragging utterance of a drunken man or of bulbar paralysis, and secondly there was difficulty in finding the proper word and in clearly grasping the spoken language of others. The similarity to asthenic bulbar paralysis is great. There is general prostration, most noticeable in the parts supplied by bulbar nerves, and furthermore, to which the author calls particular attention, there is a very rapid fatigue. When beginning to speak the patients could do so tolerably distinctly and correctly, but almost immediately the mechanism seemed to become exhausted and the effort had to cease. This was more noticeable as the patients approached recovery. A strong effort of the will would for a few minutes mend the trouble, and a stimulant (brandy) acted in the same way, but the improvement was but temporary. [But here we have, in addition to "bulbar" exhaustion, interference with the cerebral center of speech, showing that there is, in all probability, an affection of the brain, medulla, and muscles—a condition of affairs that may throw some light upon the pathology of the other and more chronic functional affection.]

Convulsions from Lead and Alcohol.—It is not a late discovery that convulsions may be due to lead or alcohol, but, as the fact seems not to be very generally known, we deem it well to mention 3 cases reported by Jackson.[3] They particularly well illustrate that lead-poisoning or alcoholism complicated with nephritis makes a particularly dangerous combination. Jackson's first case, a painter aged 21, whose father had died of lead-poisoning, had wrist-drop and the characteristic lead line. After ailing a few days he had convulsions rapidly following each other, after which he was for some time in a stuporous condition, which persisted in a minor degree for several days. There was a trace of albumin in the urine, which disappeared on recovery.

[1] Deut. Zeit. f. Nerv., Nov., 1896. [2] Arch. f. Psych., Bd. xxviii. H. 2.
[3] Boston M. and S. Jour., Apr. 2, 1896.

He had no return of albumin nor of convulsions, and the author very reasonably attributes the convulsions to the lead. [But he seems not to notice what should not be forgotten, that, although the convulsions may have been due to lead, their occurrence may have been, and likely was, favored by the slight nephritis. It should be remembered, too, as was noted in the *Year-Book* for 1896, that there is such a thing as toxicopathic heredity, and the death of the father from lead is, in this relation, a most pregnant fact.]

In the second case there was a complication of alcoholism, amyloid kidney, purulent peritonitis, and syphilis, the latter two being unrecognized until the time of the autopsy. [Of this quartet it is difficult to say which integer played the most prominent part, but we agree with the author that it was the alcohol.]

Case 3 was a man of 29, a steady worker and a steady and hard drinker. He had had some dizziness on several occasions. One day this became worse, and was followed by 2 severe convulsions, and these by violent delirium. The urine contained a trace of albumin. Delirium with occasional convulsions continued until death 2 days later. [There was no microscopic change in the kidneys, but we would hesitate to say with the author that the case proves "beyond any reasonable doubt that fatal epileptiform convulsions may occur in alcoholic poisoning independent of renal disease," although the alcohol was beyond peradventure the most active etiologic factor.]

The Spinal Cord in Pernicious Anemia.—[In the *Year-Book* for 1896 some attention was given to the changes produced in the spinal cord by various abnormal blood-states, particularly pernicious anemia. The contributions of the year have served only to strengthen the conclusions there given, notably an additional contribution by Nonne[1] and one by Lloyd.[2]] The patient of the latter presented during life no symptoms that might not have been accounted for by the pernicious anemia (hemoglobin, 23%; red cells, 1,280,000). Postmortem, there was found marked degeneration of both posterior columns, and changes less pronounced in the pyramidal tracts. The direct cerebellar tracts, contrary to the rule, were found intact. Some notice must be taken of a paper on this subject by Teichmüller[3] with report of a case from the clinic of Prof. F. A. Hoffman in Leipsic. [An attempt is made, on the strength of the microscopic examination, to disprove the generally accepted statement of Nonne, that in pernicious anemia the white substance alone is affected, the nerve-roots and gray matter remaining intact. But the paper contains internal evidence that the conclusions of its author are entirely without foundation, for the changes in the gray horns and posterior nerve-roots that he found on microscopic examination are palpably artefacts, produced by postmortem injury of the cord. Had the author acquainted himself with the instructive work of Van Gieson on heterotopia, and then studied a few of the grosser and finer postmortem lesions, it never would have occurred to him to publish his findings under the above heading.]

[1] Münch. med. Woch., 1896, No. 14. [2] Jour. Nerv. and Ment. Dis., Apr., 1896.
[3] Deutsch. Zeit. f. Nerv., Bd. viii. H. 5 and 6.

Locomotor Ataxia.—Leimbach[1] has made a careful study of the notes of 600 cases of locomotor ataxia occurring in the private practice of Erb. Of these, for various reasons, only 400 were found available, which is, however, a quite sufficient number for statistical purposes. He gives the relative frequency of the principal symptoms, and also the frequency with which each appears as the initial sign of the disease. The lancinating pains were, as earliest symptom, much more frequent than any other, occurring as the initial manifestation in 283 of the 400 cases. In 65 cases they occurred as second symptom, and in only 47 were they entirely wanting up to the time of observation. They remained the only symptom in some cases for from 10 to 26 years. A feeling of weakness in the legs was the first symptom in 78 cases, and the second in 113, which is somewhat surprising, as it is well known that in the early stage there is no real muscular weakness. The girdle feeling is commonly regarded as of frequent and early occurrence in this disease, but was the first symptom in only 34 cases, and the second in but 44. Paresthesia of the lower extremities is a comparatively early symptom, as it was the initial sign in 74 cases and the second in 110 cases. [It cannot be too frequently insisted upon that the presence of incoordination is never necessary to the diagnosis of locomotor ataxia. By far too many physicians give too much importance to the presence or absence of this symptom, and this assertion is borne out by the figures of Liembach.] Uncertainty in standing, even with the eyes closed, was the alleged earliest symptom in only 3 of his 400 cases, and the second symptom in only 21.

[As the symptom ataxia, or incoordination, receives too much consideration, so the slight bladder-symptoms are too much neglected. This cystic incompetence is very important, and may take the form of slight atony, so that the patient must wait a moment and strain a little to start the stream, or there may be slight dribbling of urine after urination is seemingly finished, or there may be a relative weakness of the sphincter, the patient losing a few drops before he can attend to the call of nature.] This bladder-weakness occurred in one or another form—as initial symptom 90 times, as second 119 times, and as third 74 times.

It is often stated that organic heart disease is very frequent in locomotor ataxia, so it is worthy of note that in the 300 cases in which it was examined for it was found only 6 times—viz. 2 cases of mitral insufficiency, 1 of mitral insufficiency with aortic stenosis, 2 of aortic insufficiency, and 1 of aortic insufficiency with aortic stenosis. There was 1 case of aneurysm of the aorta. All of these patients were undoubtly syphilitic.

The Distribution of Anesthesia in Locomotor Ataxia.—The study by Laehr[2] of 60 cases of locomotor ataxia with special reference to the occurrence of anesthesia and its distribution is a real contribution to our knowledge of this well-known disease, although Hetzig several years ago called attention to the facts elucidated. In only 5 of the 60 cases did Laehr

[1] Deutsch. Zeit. f. Nerv., 1895, Bd. vii. p. 493.

[2] Arch. f. Psych. und Nerv., Bd. xxvii. H. 3.

fail to find anesthesia of greater or less extent on the trunk, and these 5 were cases of tabes complicating general paralysis of the insane, in which the spinal affection was secondary to and much less prominent than the cerebral disease. This trunk-anesthesia, although so uniformly present, is usually not very marked, and relates more particularly to the sense of touch rather than to that

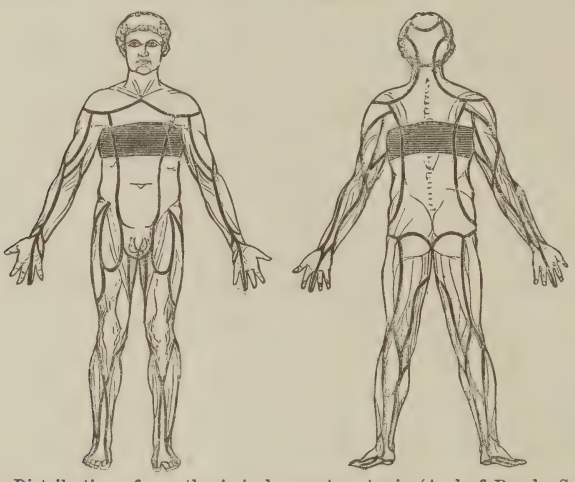

FIG. 137.—Distribution of anesthesia in locomotor ataxia (Arch. f. Psych., Sept., 1895).

of pain, in contrast to the sensory disturbance of the lower extremities, which first manifests itself as analgesia, the sense of touch often remaining normal till late in the disease. Its location on the trunk is generally at about the

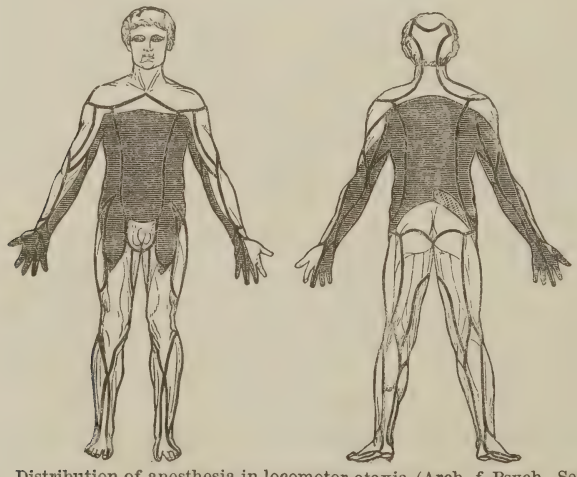

FIG. 138.—Distribution of anesthesia in locomotor ataxia (Arch. f. Psych., Sept., 1895).

level of or just below the nipple, in the form of a band reaching from the spine around to the middle line in front, and is nearly always bilateral, but the bands on the two sides may not be of equal width. In the incipient stage of the disease the bands are narrow (one or two intercostal spaces), may be incom-

plete in front or behind, the borders may be illy defined, and there may even be no distinct anesthesia, but merely an inability to locate touches with normal accuracy. When the anesthesia is very slight a prolonged examination may cause it to disappear [apparently educating it away, just as ataxics may be educated to execute movements with greater accuracy—method of Fränkel]. One of the most instructive facts elicited by the author's investigations is that the areas of anesthesia correspond not to the distribution of the cutaneous nerves, but to the spinal segments, as outlined by Thorburn, Starr, Sherrington, Head, and others. (See Figs. 137–139.) This was beautifully shown in some cases that the author was able to observe for a considerable

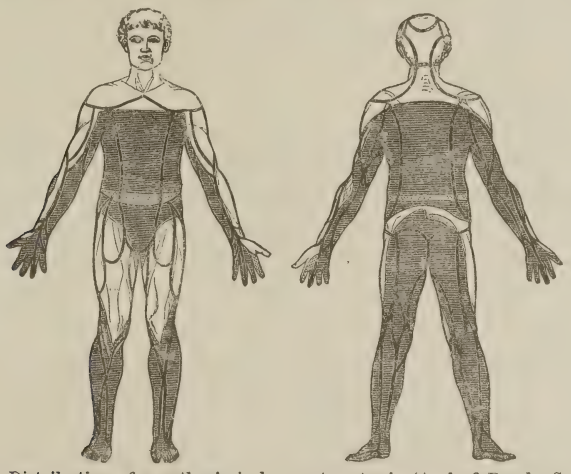

FIG. 139.—Distribution of anesthesia in locomotor ataxia (Arch. f. Psych., Sept., 1895).

length of time and watch the gradual extension upward of the anesthetic area. With great uniformity, as soon as it reached the third intercostal space it began to encroach upon the arm, at first affecting only the inner surface below the axilla, then gradually spreading over the entire inner border, and finally involving the radial side as well. He was also able to observe a similar progression downward from segment to segment. [It must not be forgotten that a peripheral neuritis, which is now known to be a not very rare complication of tabes, might cause anesthesia which would obscure the distribution of this spinal anesthesia.] It is an instructive fact that in a number of cases there were areas of anesthesia corresponding to spinal segments some distance apart, which would go to show that the pathological processes of tabes may begin in different parts of the cord at nearly the same time. It was also found that the skin at the border of the anesthetic area was often hyperesthetic to pricking, pinching, etc., and furthermore that in this hyperesthetic zone the cutaneous reflexes were very lively. The author thus explains the peculiar difference of opinion regarding the activity or absence of the superficial reflexes in locomotor ataxia. If the place we stimulate to elicit a superficial reflex (*e. g.* the sides of the abdomen for the abdominal reflexes, the inner surface of the thigh for the cremaster reflex) happens to lie within the anesthetic zone,

the reflex will be diminished or lost; if within the hyperesthetic zone, it will be lively or exaggerated. Trunk-anesthesia is a very early, but not the earliest, sensory disturbance, as some degree of anaglesia of the legs generally precedes it. Analgesia of the trunk of the ulnar nerve he finds to be much less frequent (16 in 43) than did Biernacke (14 in 20), who first described it. [See the *Year-Book* for 1896.]

Optic Neuritis in Tabes.—Bernhardt[1] contends that although choked disk may possibly occur as a part of locomotor ataxia, it is exceedingly rare, and when present is nearly always due to syphilitic lesions. He is fully in accord with those who think that tabes is, in the great majority of cases, due to specific disease, and there is nothing to prevent the occurrence of a typical syphilitic meningitis or other form of cerebral syphilis, which would cause optic neuritis in the course of tabes, but be entirely independent of it, except in a community of etiology.

In the **gastric crises** of tabes Bechterew[2] strongly recommends oxalate of cerium in the usual dose for the vomiting of pregnancy—7 to 20 gr. t. i. d.

Pachymeningitis Cervicalis Hypertrophica.—Köppen[3] reports 2 cases that put a new face upon this disease as first described by Charcot. They vary from the classical type not only clinically, but also in the postmortem findings, and would tend to show that the disease is not so exceedingly rare as has been supposed. The most striking and characteristic symptoms have always been supposed to be the extremely chronic course, severe and long-continued pain, marked atrophy limited to the upper extremities, and absence of cerebral symptoms. Köppen's first case ran its full course from inception to fatal termination in 9 months; there was entire absence of pain, only very slight atrophy limited to the scapular muscles, and there was some speech-defect and slight dementia. In the second case the lower extremities were involved: there were optic atrophy, inequality of the pupils, weakness of ocular muscles, and some mental hebetude. A very careful microscopic examination was made in both cases, which led the author to believe that the disease is often of syphilitic origin, that it is not in reality a pachymeningitis, but that the pia and arachnoid are affected equally early and extensively, and that the spinal cord itself is, through its vessels, attacked coincidently with, and not secondarily to, the membranes.

Painless Tumor of the Cord.—In this connection it might be well to mention Bailey's 2 cases of tumor of the spinal cord,[4] for in tumor of the cord, as in spinal pachymeningitis, pain is justly considered one of the most prominent symptoms and one of the most important means of localization. Case I. was a woman of 65, who died of acute pulmonary edema and Bright's disease, and purely by accident a psammoma of the spinal cord was discovered at the autopsy. The growth was intradural, between the seventh and eighth posterior roots, $\frac{3}{4}$ in. long, $\frac{1}{8}$ in. wide, and $\frac{1}{10}$ in. thick. It had caused no symptoms during life. Case II. was a woman of 29, who had had a tumor of

[1] Berl. klin. Woch. July 15, 1895.
[2] Therap. Woch., June, 21, 1896.
[3] Arch. f. Psych. u. Nerv., Bd. xxvii. H. 3.
[4] Jour. Nerv. and Ment. Dis., Mar. 1896.

unknown character removed from the abdomen by celiotomy, and another from the third rib. In the course of 6 years she had been paralyzed 3 times, all 4 extremities being affected. The last attack proved fatal some 6 months after its onset. There was at no time any pain, spontaneous or on movement, nor was there tenderness on percussion over the spine. Postmortem, a greatly degenerated gumma was found on the ventral surface of the cord, involving the first to the fourth anterior cervical nerve-roots. It was $\frac{1}{8}$ in. thick. Clarke[1] has also reported a case of tumor of the spinal canal that ran its course without pain. The growth was a soft endothelioma, was extradural, extended from the fourth cervical to the first dorsal vertebra, and involved all the posterior roots in this region. The author attributes the absence of pain to the soft character and slow growth of the neoplasm. [But, whatever the cause, it again shows that absence of pain does not exclude tumor of the spinal canal.]

Lumbar Puncture.—[We last year devoted some space to a report on lumbar puncture, and the operation continues to receive considerable attention from neurologists and surgeons.] Rieken,[2] the assistant of Quincke, who was the first to systematically employ this measure as a diagnostic and therapeutic aid in various cerebral and spinal affections, gives a full report of the 34 cases operated on from August, 1891, to April, 1895. [The paper adds but little to our report of last year (*Year-Book* for 1896, p. 644), but serves to confirm the conclusions contained therein—viz. that the operation is not dangerous, is reasonably easy to perform, may be of great diagnostic worth, but is therapeutically almost worthless.] Of the 34 cases, but 1, the last, seemed to show that the puncture and withdrawal of fluid aided recovery or possibly saved life. This case was, briefly, as follows: A child of 1 year [the age is given as 6 months in the tabular summary] became suddenly ill with convulsions, vomiting, and cyanosis, followed by fever, headache, anorexia, and tenderness of the extremities to pressure. After 10 days there was some improvement, followed by relapse with fever as high as 107° F. in the evening. (A 5-year-old brother had been sick with something similar, but was convalescent.) The attending physicians made a diagnosis of cerebrospinal meningitis, and 19 days from the onset the child was taken to the hospital. There it was found to have high fever, tenderness of muscles to pressure, and slow pulse. The patient was restless and constantly screamed. Puncture was done with the temperature at 103.1°, and 27 c.c. of turbid cerebrospinal fluid withdrawn, rich in leukocytes and other cells. Within 2 hours after the puncture the temperature was normal; it remained so, and the child made a rapid recovery. The author thinks it possible that recovery might have ensued without the operation, but even in that event believes that it hastened recovery.

A word may be added concerning the technic as practised by Quincke: A trocar and cannula (sizes 3 to 7.5 cm. long, 0.6 to 1.2 mm. thick) are employed, and the site chosen is 5 to 10 mm. from the middle line, and in children on a level with an interspinous space, in adults opposite the junction of the middle with the lower third of a spinous process. The point is directed so as to reach the

[1] Brain, 1895, Summer and Autumn No. [2] Deutsch. Arch. f. klin. Med., Oct. 25, 1895.

dura mater about in the middle line, and in adults the needle must be directed slightly upward, as the vertebral arches slightly overlap. The depth necessary to pierce the dura will vary from 2 to 7.5 cm., according to the age of the patient and thickness of the soft parts. The puncture is made in the 2d, 3d, or 4th lumbar interspace, which is, of course, below the termination of the spinal cord, and the danger of injuring the cauda equina is minimal. If the patient complain of headache, dizziness, or nausea, or there occur jerking in the legs, the withdrawal of fluid is at once stopped. It is best not to aspirate, but to let the liquid slowly run away from its own pressure. When prolonged drainage is desired a narrow lancet is passed along the cannula into the canal and a small slit made in the dura. Local edema follows this procedure, but no ill effects have been observed.

The most important contribution to the subject in this country is that of Jacoby.[1] He reports 35 cases, as many as 7 punctures being made in 1 case. They were as follows: supposed tubercular meningitis, 17; purulent meningitis, 1; meningitis with abscess, 1; tumor of the brain, 6; hydrocephalus, 4; ventricular hemorrhage, 4; spinal hemorrhage, 2; acute mania, 3. He punctures between the 3d and 4th or 4th and 5th lumbar vertebræ, using as a guide a line drawn from crest to crest of the ilium. This passes over the 4th lumbar spine. The needle is inserted about 5 mm. from the median line, although children may be punctured directly between the vertebral spines. He uses anesthesia as a convenience, not a necessity. The depth necessary to reach fluid is 2 to 6 cm., but he alludes to a case in which Goldscheider was obliged to penetrate 8 cm. (over 3 in.). Jacoby agrees with other authors that it is better not to aspirate, and that accidents are very rare, but mentions the danger pointed out by Stadelmann, that of drawing infection from the cranial cavity into a heretofore uninfected spinal canal. The operation is simple, but not altogether easy, and the author advises preliminary practice on the cadaver. A dressing of iodoform-collodion suffices. No permanent benefit was attained by the operation in any cases, a transitory amelioration in a few. In brain-tumor the withdrawal of fluid is apt to cause intense headache for about 15 minutes, followed by considerable relief. In a case of compression-myelitis with great pain Goldscheider repeatedly aspirated and injected a solution of cocain into the dural sac, but to no purpose. Freyhan punctured in 1 case supposed to be tubercular meningitis; tubercle-bacilli were found in the fluid and the patient recovered, but this case is unique thus far. The procedure, however, is of undoubted diagnostic value. The character of the fluid may give valuable information. In tumor and abscess of the brain the fluid contains only 0.4 to 0.8% of albumin and does not spontaneously coagulate, while in meningitis it contains about 1.6% of albumin and a coagulum spontaneously separates. Lichtheim's first employment of the method for purposes of diagnosis will illustrate its possibilities: A patient with otitis presented cerebral symptoms; fluid removed by puncture contained streptococcus pus, and therefore a diagnosis of meningitis was made, which was confirmed by autopsy. Jacoby had a similar

[1] N. Y. Med. Jour., Dec. 28, 1895, and Jan. 4, 1896.

case in which the diagnosis lay between abscess alone and abscess complicated with meningitis. Lumbar puncture revealed pus; operation was consequently discountenanced, and the autopsy revealed abscess of the cerebellum and purulent meningitis. He found tubercle-bacilli in 11 of the 17 cases of suspected tubercular meningitis, but as autopsies were not obtained positive conclusions cannot be drawn. He had 1 case, however, in which the correct diagnosis of tubercular meningitis was made by means of the puncture before the symptoms of the disease were sufficiently advanced to make a diagnosis possible. It is to be remembered that in a few cases in which meningitis was confined to the brain the withdrawn fluid was perfectly normal. Two of Jacoby's cases are exceptional: A woman of 22 after a fall upon the buttocks and lower part of the spine rapidly became completely paraplegic, with anesthesia, loss of reflexes, and retention of urine. She was punctured between the 4th and 5th lumbar vertebræ, and about 15 c.c. of dark blood were drawn off. Thirty minutes after the operation the anesthesia had improved, but motion was unaffected. In 24 hours she could move both legs; the third day she recovered power over the bladder, and in 2 weeks was nearly well, but several months later still showed some "weakness in the peronei and extensors of the ankles and absent knee-jerks." A young man was violently thrown from a bicycle against a stone fence. There was immediate weakness of both legs, with slight anesthesia and incontinence of urine and feces. Puncture was done about 24 hours after the accident between the 3d and 4th lumbar vertebræ, and about 20 c.c. of dark fluid blood withdrawn. There was no immediate effect, but he began to improve on the fourth day, and 4 weeks after the injury had completely recovered except for slight anesthesia about the perineum and genitals and some impairment of motion of the toes. The author closes as follows: "As a result, therefore, of my experience and that of others, we may summarize the acquired facts as follows: By means of lumbar puncture cerebrospinal fluid can be easily removed from the subarachnoid sac of the spinal cord and from the cavities of the brain. Therapeutically, it is only of direct value as a palliative through the reduction of increased pressure; it may perhaps prove of more service indirectly as the first step to local treatment of the cord and brain. Diagnostically, it possesses great clinical advantages in the diagnosis of the various inflammatory affections of the cerebral membranes and in the recognition of intraventricular hemorrhage, as well as of hemorrhage within the spinal canal. From the facility with which this little operation can be carried out it should not be long before lumbar puncture will form a part of the routine work of every practising physician."

The following case of Kiliani[1] and the 2 of Jacoby just cited are probably the only ones of the kind on record: A man of 45 fell 20 feet, striking on his back; on examination 13 hours later he was found to be paraplegic, including paralysis of the bladder and rectum, and anesthetic below the level of the 3d lumbar vertebra. For 5 days there was absolutely no change, when lumbar puncture was performed between the 3d and 4th vertebræ

[1] N. Y. Med. Jour., Mar. 14, 1896.

and 8 c.c. of tar-like blood withdrawn. One hour after the operation the anesthetic zone was smaller and in some places less pronounced, and there was slight motor improvement. The condition then remained stationary for 4 days, when the patient suddenly died of asphyxia while the bed was being changed.

The subject of lumbar puncture was rather extensively discussed at the last German Congress for Internal Medicine,[1] and was introduced by Lenhartz, who had performed the operation 230 times on 126 patients. He places the patient on the side and punctures in the middle line between the 3d and 4th lumbar vertebræ. Regarding the information to be thus gained he says: 1. It allows of a good estimate of the amount and pressure of the cerebrospinal fluid. 2. The proportion of albumin in the fluid is of diagnostic value. Over $\frac{1}{4}$ to 1000 speaks for the presence of inflammation, with some exceptions, as 2 to 4 per 1000 has been observed in tumor and apoplexy. 3. The specific gravity of the fluid is of no import. 4. The presence of numerous cells indicates inflammation. 5. The presence of tubercle-bacilli is positive evidence of tubercular meningitis. In the last 9 of 19 cases examined they were found. To facilitate finding the bacilli Lenhartz allows a bit of absorbent cotton to sink into the fluid, where it becomes permeated by the germs, and is then tapped out on the cover-glass. In epidemic cerebrospinal meningitis diplococci are found free or in the cells; also streptococci. 6. The color of the fluid is of small value; *e. g.* in cerebrospinal meningitis it may be purulent, seropurulent, slightly cloudy, or perfectly clear. It is bloody principally in pachymeningitis and head-injuries. Therapeutically, he uses puncture in—1. Acute and chronic serous meningitis; 2. Severe chlorosis with pronounced nervous symptoms; 3. Acute cerebral edema caused by injuries to the head; 4. He has also seen some relief in brain-tumor. Krönig found tubercle-bacilli in 4 out of 5 cases of tubercular meningitis. He had seen relief in serous meningitis, the headache of chlorosis, and in 1 case of acute meningitis. Goldscheider uses the same technic as Lenhartz, avoids aspiration, has seen no evil results, and found the tubercle-bacillus in 3 cases: they were, however, cases in which the diagnosis was not difficult. In epidemic cerebrospinal meningitis he had generally found increased tension, but seldom pus. As opposed to the opinion of Lenhartz, he thought increased pressure of some importance, and in answer to a question raised by him said there was such a thing as serous meningitis, but it was rare. He had found puncture to afford only transient relief of symptoms. Schultze believed in spinal puncture for chlorosis, calling it "white phlebotomy" as opposed to "red phlebotomy," which had been recommended in this affection. He had seen subsidence of most threatening symptoms in tubercular meningitis after puncture, but thought that in brain-tumor trephining afforded more relief from pressure. In 1 case of enormous hydrocephalus he had seen the fluid only drop very slowly. Ewald called attention to the fact [noted in the *Year-Book* for 1896] that sudden death had followed puncture in cases of brain-tumor.

[1] Neurolog. Centralbl., May 15, 1896.

Hansemann supported Goldscheider in affirming the existence of a serous meningitis, as he had seen 2 cases postmortem. Lenhartz in closing said that when the pressure of the fluid fell to 60 mm. of water he terminated the operation. He thought the slow dropping of fluid noticed by Schultze was due to occlusion of the cannula. He never used an anesthetic. With one exception he had seen no ill effects; generally there is immediate relief of headache, dizziness, and vomiting. The exception was a case that suddenly terminated fatally 4 hours after tapping.

Syringomyelia.—[Syringomyelia has, until quite recently, been considered to rank among the clinical curiosities, and is, we have reason to think, still unknown to some physicians.] Dimitroff[1] in reporting a new case has collected from the literature of about 8 years (from 1887 to October, 1894) observations of 297 cases. Of these, 7 cases do not properly belong in this category, and of the 201 cases studied only clinically, some may have been incorrectly diagnosed, but 61 cases were observed clinically and postmortem, and 23 were only studied after death—a total of 84 autopsies.

Syringomyelia and Morvan's Disease.—[It is now very generally conceded by neurologists that Morvan's disease is identical with syringomyelia, although the fact that Morvan has been able to collect such a large number of cases from the comparatively small population of Brittany remains unexplained.]

FIGS. 140, 141.—Deformities in Morvan's disease (Neurolog. Centralbl., May 15, 1896).

Bielschowsky[2] reports a case from Mendel's clinic under the title of Morvan's disease, and then proceeds conclusively to show that it is none other than syringomyelia. The patient, a woman of 40, was seen 6 years after the beginning of the affection, and showed the typical trophic changes of Morvan's disease—viz. loss of phalanges following painless whitlows, marked arthropathy of one wrist-joint, and slight affection of both shoulder-joints (see Figs. 140, 141) There was also some trophic change in the skin, and above the left elbow a

[1] Arch. f. Psych. u. Nerv., Bd. xxviii. H. 2. [2] Neurolog. Centralbl., May 15, 1896.

scarlike fold not unlike Dupuytren's contracture. [This patient had never been exposed to trauma of any kind, and the case offers all but conclusive evidence that the arthropathies, whitlows, etc. of syringomyelia are a truly trophic trouble and depend in no wise upon the analgesia, as has been suggested by some.] (See following case.)

Korb[1] reports a case of syringomyelia with careful postmortem examination. Although typical, it is of unusual interest as showing to a marked degree the changes described by Morvan in the affection named after him. (See Fig. 142.) The trophic affection of the bones and connective tissue was marked, whereas the muscular atrophy, so frequent and generally so pronounced in syringomyelia, was almost wanting. This is interesting and instructive in view of the fact that the disease-process in the cord was limited to the central part and posterior horn, the anterior part of the cord being intact. [This would indicate, to us, a different location of the trophic-cord centers for muscles and bones, and we cannot at all agree with the author in attributing the deep and extensive bone-changes entirely to infection from the ordinary accidents of daily life, which progressed to this serious degree simply because the conservative warning of pain was absent. (See preceding case.) This theory would not account for the cases in which the first of a series of whitlows is painful, the second less painful, and the others painless. Such cases are not extremely rare. We have seen 2 such. The case is of interest as showing some anesthesia to touch, formerly supposed to be always absent, now known to be at times present, in syringomyelia, and a delay in pain-conduction which has been but seldom mentioned in this disease.]

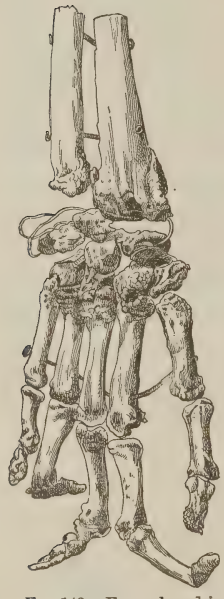

FIG. 142.—From hand in Morvan's disease (Deutsch. Zeit. f. Nervenheilk., June 2, 1896).

[It should be remembered that anesthetic leprosy may very closely resemble syringomyelia, especially of the type of Morvan, and since the investigations of Zambaco a few years ago it is reasonably certain that some cases before thought to be syringomyelia, and even some of the cases seen and reported by Morvan, were indeed cases of leprosy.] Presumably such a case is reported by Prus,[2] although neither the history nor the symptoms were typical of syringomyelia. In the blood the author found a bacillus that he considered to be the lepra-bacillus. The deformities of the fingers produced by painless whitlows could be easily mistaken for those of Morvan's disease.

A very unusual case is that reported by Thomas[3]—a boy of 6, whom he considered to be suffering from syringomyelia of the Morvan type. Although the child had the deformed fingers and thermoanesthesia, the course and symptoms of the disease were sufficiently atypical to make the diagnosis doubtful.

[3] Rev. méd. de la Suisse Rom., No. 11, 1895.

[It must not be forgotten that dissociation of sensation, loss of temperature-sense, and analgesia, with preservation of sense of touch, are sometimes found in disease of the peripheral nerves and in lesions of the spinal cord other than syringomyelia. Indeed, Pic and Regaud have reported their occurrence in compression of the cord from Pott's disease, when the autopsy showed no lesion of the cord whatever.]

Landry's Paralysis.—The most important contribution of the year to the study of acute ascending paralysis is that of Pearce Bailey and Ewing.[1] They give the report of a case, complete clinically and pathologically [and what is of peculiar value in their work is the examination of the spinal cord by means of the latest and most approved technic—Nissl's stain]. The clinical history is sufficiently typical: A woman of 36 years, a beer-drinker, with negative previous history and examination of whom was negative as regards evidence of syphilis, was attacked Nov. 19 with vomiting. This continued, and on the third day she went to bed in an exhausted condition. She had, too, occasional attacks of vertigo and fainted on attempting to rise from bed. On the next day (Nov. 23d) she rather suddenly lost power in the legs, and on Nov. 24th there were added paralysis of the left arm and paresis of the right. Sensation was normal. On examination Nov. 25th the pulse was found to be 100 and regular, the temperature 101.4° F., the respirations 28, the urine of a specific gravity of 1.030, free from albumin, but containing a few hyaline casts, the thoracic and abdominal viscera normal. Both legs and the left arm were completely paralyzed, and the right arm nearly so. There was some left ptosis. Sensation was normal, there was no pain or tenderness, the sphincters were intact, and the reflexes were lost. Electric examination the day before death showed diminished faradic response. Nov. 26th she vomited repeatedly and was sleepless, and on the 27th she complained of headache and dyspnea. On the 29th the urine contained a trace of albumin, the dyspnea increased, dysphagia appeared, and during the day advanced to aphagia; there was marked dysphonia, and the patient died that evening, 10 days after the beginning of the vomiting and 6 days from the onset of the paralysis. The autopsy disclosed "congestion and edema of the lungs; acute degeneration of the liver and kidneys; acute hyperplastic splenitis." To the naked eye the nervous system presented nothing abnormal. Microscopic examination of the cauda equina, nerve-roots, and spinal meninges was negative, except for the presence of slight circumvascular infiltration of round-cells. The gray matter of the spinal cord was extensively affected throughout the entire length of the cord, being much more involved in some areas than in others. The lesion consisted in intense congestion of all the blood-vessels, especially of the ramifications of the central branch of the anterior spinal artery. In the cervical region there were several capillary hemorrhages, and some of the arterial twigs contained thrombi composed of multinuclear leucocytes. Nearly all the vessels showed a pronounced circumvascular infiltration with small round cells. In some places this infiltration had extended beyond the circumvascular sheath, and the small cells were gathered in such

[1] N. Y. Med. Jour., July 4 and 11, 1896.

numbers as to form what may be properly regarded as miliary abscesses. Furthermore, there was a diffuse cellular infiltration in the gray matter, which sometimes extended slightly into the white matter. At some levels congestion and exudation were so intense that nothing could be distinguished but the round-cell infiltration and the detritus of neuroglia- and ganglion-cells. Where the process had extended into the white matter, as was observed in the cervical region only, the fibers were absent, and their places occupied in part by large mononuclear cells, with homogeneous or granular protoplasm.

Before detailing the degenerative processes in the ganglion-cells, it may be well to briefly describe a normal human ganglion-cell of the anterior horn as it appears when stained by Nissl's method (Plate 11, Fig. 1). The cell-body under these conditions contains a number of chromophilic masses, larger and grouped concentrically about the nucleus, arranged in rows along the cell-borders and prolonged as slender rods into the dendrites. These bodies are not found in the axis-cylinder process. The significance of these chromophilic bodies is not known, but they are believed to be a characteristic and normal element of the ganglion-cell. Besides these bodies, smaller granules are scattered through the cytoplasm, giving the appearance of a fine network. Some areas of diffuse, structureless, greenish pigment are often encountered in normal ganglion-cells of the adult, a feature which is much more conspicuous in old age (Plate 11, Fig. 2). By this method of staining, the nuclear membrane is distinct, and is separated from the deeply staining nucleolus by a clear area in which may occasionally be made out a fine granular network.

The abnormities in the ganglion-cells observed in the present case consisted principally in the partial or complete absence of the chromophilic masses (Plate 11, Figs. 3 and 4). In cells in which the lesion was least marked the absence of chromphilic bodies was noted only in the central portions of the cells. Other cells were seen in which the cytoplasm was entirely bereft of chromophilic bodies, and their places were occupied by a multitude of fine, rather deeply-staining granules, which gave to the cell-body a very peculiar "dusty" appearance. Further, in many cells even the finer bluish particles were absent, and in these cells especially, less often in the others, the nuclear membrane was indistinct, irregular, or granular, and the nucleolus fragmented or absent (Plate 11, Fig. 5). Finally, in the areas where evidences of exudative inflammation were most pronounced, many shrunken and irregular cell-bodies and collections of deformed chromophilic bodies without visible cell-nuclei were with difficulty to be recognized. The fragmentation of cell-processes, as observed by Oettinger and Marinesco, was occasionally encountered, but in such situations as to render its pathological significance uncertain. The cells of Clarke's columns were only slightly affected, and offered a sharp contrast to the intensely inflamed anterior horns. The sacral region and conus medullaris were the least affected portions of the cord, and were in places almost normal, which would readily explain the integrity of the sphincters. The changes in the gray matter throughout the entire cord were but slightly marked in the posterior horns. The lesions in the medulla and pons were chiefly marked in

PLATE 11.

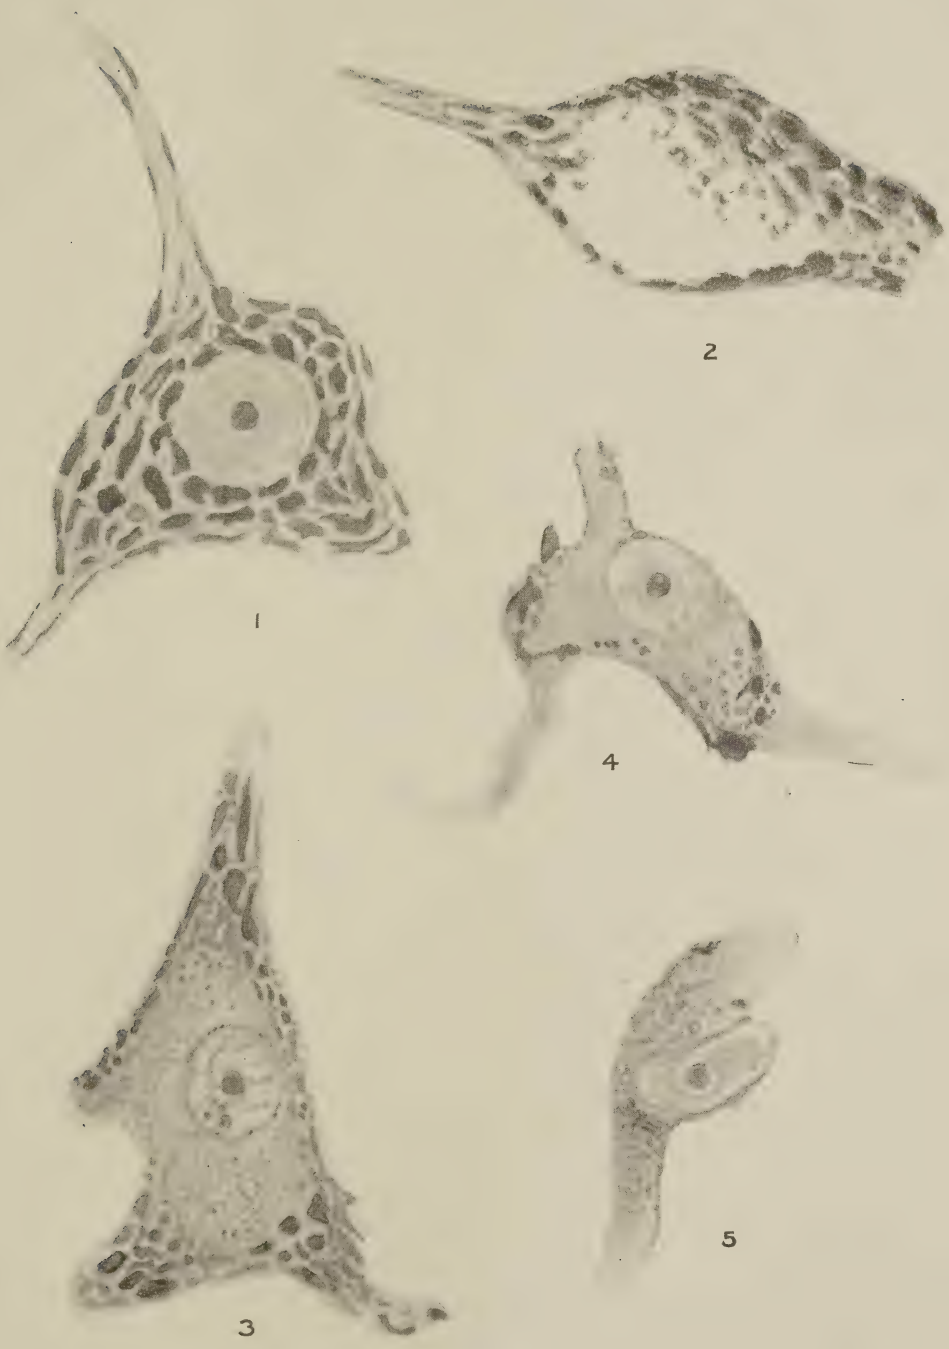

FIG. 1.—Normal human ganglion-cell of the anterior horn of the spinal cord. FIG. 2.—Increase of pigment in the senile ganglion-cell. FIGS. 3–5.—Degenerative changes in the ganglion-cell. (N. Y. Med. Jour., July 16, 1896.)

the gray matter along the floor of the fourth ventricle and in that of the pons, although the white matter and periphery were not entirely uninvolved. The changes were similar to those described in the cord. The nuclei of all the cranial nerves were more or less damaged, those least affected being the sixth and seventh. The changes in the nuclei of the third nerves were chiefly in the ganglion-cells which lie internally. The nucleus funiculi teres was but little affected. The basal ganglia showed the circumvascular lesions and numerous small foci of cellular infiltration. The internal capsule was intact, but the motor cortex presented the same small collections of round-cells and ganglion-cells in the milder stages of degeneration. The temporosphenoidal lobes were normal. The marked lesions of the medulla extended slightly into the middle peduncles and the lateral lobes of the cerebellum.

No bacteriologic examination was made either by culture or by animal inoculation. Sections from various levels were stained by Löffler's alkaline methylene-blue and by Gram's method, but no bacteria were found. [It is greatly to be regretted that the peripheral nerves were not examined, for the terminal filaments, and even the nerve-trunks, may be degenerated when the nerve-roots remain normal.] In addition to their original work the authors give a critical review of all carefully observed cases of Landry's paralysis in which an adequate microscopic examination was made. [It is the most judicial and advanced review of the subject with which we are acquainted, but for the sake of brevity we shall confine ourselves to their conclusions, which follow :] "Acute ascending paralysis is an acute toxemia in which the poisonous agent affects chiefly the nervous system.

"The commonest seat of the lesion is in the spinal cord and in the medulla, and it may be present in the cortex and in the nerve-roots. When in the spinal cord the lesion is that of acute anterior poliomyelitis—namely, an acute exudative inflammation following the distribution of the central branch of the anterior spinal artery, with cellular infiltration of the circumvascular sheaths, degeneration of ganglion-cells, loss of structural elements, and with or without degeneration of the anterior roots. The lesions in other parts of the cerebrospinal axis are of a similar nature.

"The evidence that the lesion of typical Landry's paralysis may exist in the peripheral nerves alone is based upon a single case reported 20 years ago by Dejerine. When the lesion affects the peripheral nerves there are increase of neuroglia-cells and degeneration of nerve-fibers.

"It is at present impossible to deny that acute ascending paralysis may run a fatal course without leaving demonstrable histological changes in the nervous system. It is certain that the cases with negative pathological report did not present the marked vascular lesions of acute anterior poliomyelitis, but it seems probable that in these cases there were changes in the ganglion-cells demonstrable by delicate methods. From present data it seems to us impossible to distinguish by the clinical symptoms the different types of lesions."

[A goodly number of cases are reported as Landry's paralysis that are simply typical cases of multiple neuritis affecting the lower extremities before

the upper.] Such an one is that of Bowie.[1] A lad of 17, after exposure and influenza and exposure again, rapidly became weak in the legs, and then arms, with some pain and soreness. There was moderate anesthesia of the feet, loss of the knee-jerks, and intact sphincters. Improvement was rapid, so that in 2 months he was able to walk. A similar case is the 1 reported by Pailhas.[2] The weakness in the legs appeared coincidently with what was supposed to be influenza. The patient began to improve at the end of 2 weeks, and the disease ran the ordinary course of multiple neuritis except for a slight recrudescence caused by exposure to cold. Diller and Meyer[3] report a case as one of acute ascending paralysis, which ran a course of more than 3 months before the fatal termination. The only postmortem finding was moderate degeneration of the pyramidal tracts. [As the brain and peripheral nerves were not examined, the case is very incomplete, and it is exceedingly doubtful if it should be classed as one of Landry's paralysis.]

MENTAL DISEASES.

Mental Changes in Graves' Disease.—Maud[4] points out the changed mental state in cases of Graves' disease, dwelling especially upon their motor restlessness, which sometimes almost imitates a chorea, and which is present in subacute mania and neurasthenia. Its value is that it expresses their mental attitude as well. They are very subject to fright—often have hallucinations of sight and sometimes of hearing. The memory is usually much impaired. Their mental processes are fragmentary, so that Sir James Russell Reynolds has denominated it a chorea of ideas. They have no fixity of attention, and often present a distinct tendency to melancholia. Hysteria and the psychic changes of hysteria are frequently present among them, and in rare cases the disease is marked by the development of acute mania.

The Breaking-strain of the Ribs in the Sane and Insane.—Campbell[5] gives the results of carefully conducted experiments to determine the breaking-strain of ribs in cases that had suffered from mental disease and those not thus affected. He gives the average breaking-strain of the ribs of 58 insane patients, for males, 41.04 lb. against the convexity, while in 50 cases of the noninsane the breaking-strain was 42.73 against the convexity. For females the proportion was 20.68 lb. against 23 lb. These figures tend to show that the influence of chronic wasting diseases in hospital and other similar cases is practically equivalent to that attributable to mental disturbance. In general paresis, however, there was an unequivocal diminution of the resisting power of the ribs, their breaking-strain falling in some cases below 20 lb. in the male. Microscopic examination also disclosed architectural deficiencies.

The Polyneurotic Psychoses.—Ferrari[6] discusses the mental disturb-

[1] Lancet, Apr. 4, 1896.

[6] Revista Sperimentali di Freniatria e di Medicina Legale, translated for the Alienist and Neurologist, Jan., 1896.

ances that frequently occur in multiple neuritis, and which have been denominated by some as a special form of psychosis under the term polyneuritic psychosis. He points out very pertinently that this mental disturbance only occurs in a polyneuritis that is the result of some particular poisoning, especially lead and alcohol, and denies its being a special mental manifestation, but that it is characteristic of the particular poison only. The article, however, reviews the question of psychical disturbance associated with multiple neuritis, and lays stress upon the peculiar character that usually dominates it—namely, the memory disturbances. Quiet cases of delirium tremens present precisely the same picture that is shown in the mental disturbance of alcoholic multiple neuritis, with the addition only of hallucinations. The mental disturbance of lead-poisoning, whether polyneuritis be present or not, is always the same. The main consideration is that a diffuse poison does not elect certain elements of the nervous system to the exclusion of all others, and the discussion goes to show that the arbitrary distinction of central and peripheral disease must be given up.

The Knee-jerk in Psychiatry.—Cramer[1] reports results of the study of 2384 cases, from which the following conclusions, among others, were drawn: Progressive paralysis is the only form of insanity with a definite relation of the knee-jerk in a certain proportion of cases. Absence of the knee-jerk in cases of insanity in which alcoholism, exhausting excitement, and severe lesions of the nervous system can be excluded should arouse suspicion of general paralysis, and is therefore a symptom pointing to bad prognosis. In the convalescence of mania, or in chronic mania, or in the acute forms of paranoia, and the alcoholic psychoses, absence of the knee-jerk is only of bad prognosis when signs of extreme collapse are present. Increased knee-jerk is only of bad prognosis when combined with advanced idiocy or symptoms of general paralysis. Increased knee-jerk is only rarely important in differential diagnosis. In the course of chronic paranoia increase of the knee-jerk with other symptoms points to an exacerbation. Neurasthenia seems always to be accompanied by increased knee-reflex. Cases of general paralysis with absent knee-jerk seem to have a longer course, with more marked depression and with rare periods of excitation. Absence of the knee-jerk after epileptic attacks allows the exclusion of simulation. Smith called attention to the great value of Sommer's instrument for registering the knee-jerk. Mendel said that he had failed to get the knee-jerk in only 1 case of functional psychosis. In this case, 1 of apparently recent mania, the patient recovered, but in 2 years proved to be paretic. Mendel prefers the terms "strong" and "weak" to "increased" or "decreased" as applied to the knee-jerk.

Heredity and Alcoholism.—Le Gendre[2] again takes up this question and presents it in an instructive manner. He points out that clinical observation teaches that the children of alcoholic parents may possess either an innate desire for drinking alcohol or purely functional troubles of the nervous system

[1] Neurolog. Centralbl., 1895, No. 19; Am. Jour. Med. Sci., Jan., 1896.

[2] Rev. prat. d'Obstét. et de Pædiat., Sept., 1895.

or organic lesions of the nervous centers. The taste for alcoholic drinks remains in abeyance, like many other hereditary aptitudes, until some occasion leads to its manifestation. The tendency usually appears between 15 and 25 years of age with boys; girls also experience this imperious desire for drink, but less frequently.

The dynamic troubles of the nervous system which may appear in the descendants of alcoholic parents may implicate any or all of their functions. Moral sensibility is affected. They are impressionable and emotional. Often sensibility to pain is modified symmetrically in the extremities, especially in the direction of exaggeration, but sometimes it is diminished. Reflex excitability is exaggerated, and explains the tendency to the frequent incontinence of urine. Hysteriform and epileptiform convulsions are not rare as the result of slight exciting causes. Nocturnal terrors are frequently observed among such children. Disturbances of the mental faculties are cited. He speaks of the arrest of a normal development of the intelligence, especially after early years of precocity, and cites the growing number of adolescent assassins. The author then calls attention to the anatomic lesions of the nervous centers among this class, which are frequently observable in the fetus and render development of the brain impossible in part or in whole, producing anencephaly, hydrocephaly, and porencephaly, and slighter degrees of developmental difficulties. This may only manifest itself at the period of adolescence and puberty, but indicates that the organs started out with lessened capacity for development. The author calls especial attention to epilepsy. In 60 families where the parents were alcoholic there were 301 children; of the 169 that survived early life, there were 60 epileptics. He calls attention to the statement of Lancereaux, who long ago pointed out the special physical conformation of such offspring. Ordinarily of slight stature, poorly developed, the skull and upper portion of the face is usually asymmetrical. Sometimes one-half of the body is atrophied, the head is small, the facial expression sad. He calls attention to the experience of recruiting officers in a wine district, who noticed a diminution in the stature of recruits born in a certain year. This is explained by the fact that during that year the vintage failed and brandies were substituted as the daily beverage. He refers to Morel's observations that the use of strong alcoholic drinks in youth has a tendency to induce infantilism. In a somewhat similar way he discusses the descendants of those poisoned with lead and morphin. Transmission occurs especially if the subject of the intoxication is the mother, but is less pronounced when the male parent is affected. [While the article is a special plea from the author's point of view, it is suggestive, and brings a lot of material again into line showing that unfavorable conditions in the parent are bound to be more or less manifest in the offspring.]

Katatonia.—Kraepelin[1] recognizes katatonia as a definite morbid type, and has studied it with a view to ascertaining its actual prognosis and course.

[1] Versamml. des Sudwestl. Deutschen Psych. Vereins in Karlsruhe, 9 Nov., 1895; Allg. Zeit. f. Psych., lii. vi. p. 1126; Am. Jour. Insan., Apr., 1896.

In 63 well-marked cases, females predominating, there were 24 that had remissions; 14 of these relapsed; for the others the time was yet too short to say what the outcome would be. Twice 2 relapses and once 4 were observed. During the remissions there was only in 1 case a claim by the friends of complete mental health. The relapses generally occurred within 5 years, occasionally longer; the mental weakness was more marked each time. The disorder resembled paresis in this, with which it is otherwise also comparable, and its general tendency seems to be toward dementia. Kraepelin sums up his conclusions as follows: 1. Remissions are common in katatonia, especially in the male sex; their duration may be for years, even over 10 years. 2. During the remission the mental restoration is not complete; some peculiarities (constrained, emotional, or especially quiet disposition, irritability) still remain. 3. An individual that has been once affected with katatonia has a great chance of a relapse sooner or later. 4. We have to deal with an organic cerebral disorder, tending to a more or less pronouncedly serious condition of dementia.

Craniotomy for Idiocy.—Dana[1] reviews this operation, and reaches conclusions which are rather fully borne out by the experience of others in this field and by a certain number of cases under our own observation. He properly insists that craniotomy for idiocy is justifiable in certain selected cases. These are microcephalic idiots in whom there is no evidence of patent fontanels at birth, and those in whom hereditary syphilis, rickets, and tuberculosis can be excluded; also extreme cases of microcephaly are not to be selected, as this implies cerebral agenesis. The method by which improvement is brought about is largely surgical and pedagogic. Every such operation must be followed up by persistent and intelligent attempts to educate such children. The operation may sometimes be repeated with benefit. In epileptic cases it is not always attended by immediate cessation of the fits and the appearance of benefit, but these may occur later.

A Family Form of Idiocy.—Sachs[2] again calls attention to this disease, and refers to cases formerly reported by him under a different caption. So far, in his own observation and that of others, including the cases of Kingdon, Carter, Magnus, and Goldzieher, 19 cases are known. The chief symptoms of the affection are mental impairment observed during the first few months of life and leading to absolute idiocy; paresis or paralysis of the greater part of the body, which may be flaccid or spastic; the reflexes may be deficient or increased; a diminution of vision terminating in absolute blindness, with changes in the macula and later an optic-nerve atrophy; marasmus leads to a fatal termination at about the age of 2 years. The affection is marked by its occurrence in several members of the same family. It must be differentiated from hereditary syphilis, and sometimes presents a somewhat similar picture. For this disease he proposes the name of amaurotic family idiocy.

The Etiology of General Paralysis.—Hirschl[3] has obtained the fol-

[1] Therap. Gaz., May 15, 1896. [2] N. Y. Med. Jour., May 30, 1896.
[3] Berl. klin. Woch., 1895, No. 45.

lowing results and conclusions from an analysis of 200 cases: In 56% of cases there was a clear history of syphilis, in 25% it was probable, and in only 19% a history of syphilis could not be discovered. Soft chancres were not used in this investigation as proving the existence of syphilis. In 78 cases in which the time of infection could be fixed the interval between that and the appearance of paralysis varied from 2 to 29 years. The author thinks the cause of general paralysis is a single one, on account of the similarity of the symptoms and of the anatomic process, the latter being a diffuse encephalitis and periencephalitis. The question whether this cause is syphilis requires some explanation of the 19% of cases with negative histories. This the author disposed of by taking the histories of 63 cases with late syphilitic lesions, and finding that in only 54% was there a history of syphilitic infection, in 9.5% it was doubtful, in 36.5 there was none at all. The anatomical changes in paresis were compared with those of syphilis, especially with the interstitial hepatitis of late syphilis. Finally, some of the symptoms of paresis were found to occur in syphilis, such as reflex immobility of the pupil, double vision, optic atrophy, ophthalmoplegia, and tabes; the symptoms of general paralysis were claimed to be favorably influenced by antisyphilitic treatment, and the prevalence of the two diseases was adduced to further prove their relationship.

Juvenile Paresis.—Alzheimer[1] discusses the subject of early paretic dementia—the developmental general paralysis of Clouston and others. He analyzes 38 cases found in the literature, and adds fully detailed accounts of 3 personal observations of his own. He finds that, as regards its etiology, syphilis plays a predominant, if not, indeed, an exclusive role; that hereditary predisposition seems to favor it, and traumatism may be the immediate cause of the outbreak of the symptoms. Clinically, the tendency is toward a form of chronic dementia, without delusions, though other psychic symptoms may occur, but generally as transient phenomena. The course and prodromal stage are rather longer than in the adult type. The paralytic symptoms generally appear early, and are prominent throughout. Hemiplegias, paralytic strokes, tabetic symptoms, optic atrophy, etc. are, relatively, rather frequent. The microscopic postmortem findings are similar to those in other forms, and the same is true of the finer lesions. In 2 of his own cases he found pronounced degenerative changes in the basal ganglia.

While the cases reported show many peculiar features, they are not, in his opinion, such as would authorize us to erect them into a special clinical type. Aside from the youth of the subjects, all the peculiar features are met in different cases of paresis of older persons. This form, however, he holds, throws a certain important light on the pathology. The usual causes, other than syphilis, to which paresis is attributed—grief, care, over-strain, the struggle for existence—fail here; the paresis occurs at an epoch when physical and psychic stress are at a minimum, and the influence of syphilis is all the more marked. The developmental changes, credited by Clouston and others, can

[1] Allg. Zeit. f. Psych., lii. No. 3; Am. Jour. Insan.

hardly play a part as early as the ninth year (at which age some of the cases began), and therefore Alzheimer rejects these as an especially important factor.

Regis[1] reports 2 new cases of general paralysis with hereditary syphilis. He believes that facts of this kind show conclusively that hereditary syphilis invariably exists in juvenile general paralysis, but that in order to find it we must hunt for it without allowing ourselves to be stopped by the difficulties that attend such search. Adding these cases to Alzheimer's statistics, it will be seen that of 42 unmistakable, well-authenticated cases of juvenile general paralysis there were 37 with histories of syphilis (hereditary), in 29 of which its existence had been established with certainty, and in 8 it was probable. The father of 2 of the patients presents a cerebral condition bordering upon general paralysis. The question naturally arises if there is not some special condition which allies juvenile general paralysis to hereditary or family forms of organic affections of the nervous system.

Bresler[2] analyzes 40 cases of general paralysis collected by Ziehen under the age of 20, and reports a typical case in a girl 13½ years in which the only bad hereditary symptom mentioned is insanity in uncles and aunts. He finds that girls are more subject to juvenile general paralysis than are boys.

Vertebral Puncture in General Paralysis.—John Turner[3] gives his experience with vertebral puncture in a number of cases of general paresis for the purpose of lowering the supposed excessive intracranial pressure by this means. He refers to the cases reported by Batty Tuke in which operation was done upon the cranium for the relief of this alleged pressure. The lumbar puncture was used in 14 cases without discovering the increased pressure anticipated, and without producing any important results. He concludes that in fairly advanced cases of general paralysis such pressure as that postulated by Batty Tuke and Claye Shaw does not exist, and further states that the examinations of the fluid obtained by lumbar puncture are not in support of the supposition that they are the result of an inflammatory process.

Thyroid-feeding in Insanity.—Bruce[4] reports a second series of 60 cases. The majority of cases chosen for treatment were unfavorable, and all had received, without apparent benefit, the best dietetic and therapeutic treatment which the Royal Edinburgh Asylum could give. There were several most gratifying results in the shape of recoveries where patients threatened to pass into confirmed dementia or had remained stuporous for long periods, as in 1 case of 2 years' standing. Whether or not its action is due to the febrile process induced by the thyroid and the subsequent reaction to the fever, the answer is made that the actual and visible result of thyroid-feeding has all the appearance of a condition induced by a toxin introduced into the blood through the medium of the mucous membrane of the stomach, and it undoubtedly produces a mild feverish condition, the action and reaction to which is often of considerable benefit to the patient. It is also a direct cerebral stimulant, and may prove

[1] Mercredi méd., 1895, No. 21, May 22; Boston M. and S. Jour., Jan. 25, 1896.
[2] Neurol. Centralbl., Dec., 1895.
[3] Brit. Med. Jour., May 2, 1896.
[4] Jour. Ment. Sci., 1895, No. 139; Am. Jour. of Med. Sci., Jan., 1896.

an advantageous treatment in cases whose higher cortical cells remain in an anergic condition after acute attacks of insanity. There is also strong probability that at some periods of life the administration of thyroid supplies some substance necessary to the bodily economy.

Reinhold[1] has used the thyroid treatment in 12 cases of insanity in which there was enlargement of the thyroid gland. Only cases of parenchymatous thyroiditis were thus treated, cystic goiters being excluded. The mental affection was always of a functional nature, and occurred nearly exclusively in young subjects. In every case the thyroid gland diminished in size. Thyroid tabloids were employed, and the treatment was continued in almost all the cases for 6 weeks. The average diminution in the circumference of the neck was $2\frac{1}{2}$ cm., the greatest decrease being 6 cm. and the smallest 1 cm. A loss of weight was noted in nearly all cases. It could not be said that the mental affection was at all influenced by the thyroid-feeding. The duration of the treatment does not constitute an objection to this view, because the specific action of thyroid-treatment occurs rapidly and soon attains its maximum; thus a further extension of the treatment is not indicated. In only 1 case has the author observed an increase in the thyroid after a discontinuance of the treatment. No unpleasant effects were noted. Thus the author's observations in relation to the diminution in the size of certain forms of goiter during thyroid-feeding accord with those of Bruns.

Babcock[2] gives a record of the results reached by him in the treatment of 13 cases in the St. Lawrence State Hospital for the Insane of New York. Two recovered—a case each of melancholia and mania; 7 improved, of whom 2 will probably recover—5 cases of melancholia and 2 of mania; 4 cases underwent no change—2 cases each of mania and melancholia, all of whom were undoubtedly demented to some extent when treatment was inaugurated.

"While the mental improvement, in suitable cases, dates from the first rise of temperature, the greatest improvement accompanies the gradual subsidence by lysis of the febrile reaction. As a general rule, the higher the temperature during treatment the greater the mental reaction following its fall, and the more marked the convalescence thereby established. When temperature subsides and continues normal for 48 hours, the thyroid should be stopped and general therapeutic measures substituted. Much harm may be done if treatment is prolonged beyond this stage. Hydrotherapy, static electricity, and massage will now be indicated in most cases and found useful to promote convalescence."

Wright[3] tried the remedy on a number of varied cases of mental disease, and reached the following conclusions: 1. That the drug produced a decided reaction in all the cases, as is shown by the feverish state and quickened pulse. 2. That the patients lost in weight and became quite feeble during its administration. 3. That the patients developed an increased desire for food, and gained in weight as soon as the drug was discontinued. 4. That the effect upon the

[1] Münch. med. Woch., Dec. 24, 1895; Brit. Med. Jour., Feb. 15, 1896, p. 28.
[2] Therap. Gaz., Apr. 15, 1896.
[3] Med. News, Apr. 4, 1896.

mental state is so slight as to hardly justify the period of time and inconvenience to patient of confinement to bed and the risk incurred by the administration of the drug.

Hedlicka [1] at the Middletown State Hospital of New York used thyroid in 4 cases of general paresis, 1 case of suicidal melancholia, 1 of primary dementia, 1 of dementia following acute melancholia, 1 of puerperal insanity, 1 of paranoia, and 3 of secondary dementia. All these patients were free from respiratory or circulatory disorder. The treatment extended over 2 months, and was begun with the administration of 5 gr. daily, and was gradually augmented to 25 or 30 gr. daily. Among the effects of the drug the following are recorded: Both the pulse and respiration increased in frequency, but this increase was never extensive. There was an increase in temperature of 1 or 2 degrees. The appetite improved. The bowels were regulated, and in several cases diarrhea was produced. The elimination of urea was increased. The majority of patients lost weight while under treatment. Regarding the mental symptoms, there was noted, under moderate dosage, pronounced general psychical improvement, the mind became clearer, more active, and the manner livelier. Sleep was improved. When the dose surpassed the moderate mark, as a rule symptoms of irritation appeared. While under treatment 1 of the cases developed a left brachial monoplegia without apparent cause, which disappeared without special treatment. The case of puerperal insanity was cured. The case of suicidal melancholia, that of dementia following melancholia, and 2 of the cases of secondary dementia were temporarily improved. The case of primary dementia grew worse. In the cases of general paresis but few temporary ameliorations were noticed. The author considers the remedy more as an alterative of great value than as a curative drug.

ORTHOPEDIC SURGERY.

By V. P. GIBNEY, M. D., and H. W. GIBNEY, M. D.,

of New York.

Introductory.—The range of orthopedic surgery is still not fully settled, and, while in America we include deformities of all kinds, deformities that relate to joints, whether congenital or acquired, the range is not so broad in England. We include everything that may legitimately be regarded, both by the Englishman and the American, as distinctly orthopedic. The president of the Orthopedic Association has attempted to define the scope, and due mention is made of his paper. A Text-Book on Orthopedic Surgery by Tubby is reviewed, and one finds little or nothing relating to diseases of the bones or joints. Another English writer has published a most excellent work on Tuberculous Diseases of Bones and Joints. The contributions to the deformity and diseases of the spine, while not very exhaustive, have been somewhat frequent, and it has been our aim to present an abstract of the more prominent articles. Some space has been devoted to the subject of shoulder-braces by reason of prominence given to this subject by a well-known surgeon. Compression-paraplegia and laminectomy are considered, but we regret to say that no great advance has been made in this department. What to do with cold abscesses still remains the subject of discussion between the strictly mechanical and the operative orthopedic surgeons. Much work that is satisfactory has been done by the pathologist, and it would appear that before many years have elapsed we shall know just what to do in a given case, how to manage a cold abscess, and what kind of prognosis one may give. There seems to be opportunity for much relief from dry heat, yet the literature is quite meager, and, while the details of treatment are full enough, the actual results cannot be obtained. We certainly hope for much improvement in partially ankylosed joints, especially those of a tuberculous nature, when all signs of the disease have disappeared.

In view of the number of papers on congenital dislocation of the hip much may be expected during the coming years, although it must be admitted that the various methods of treatment are likely to confuse one. For instance: Lorenz, who has operated more successfully than any other surgeon, has written a paper on bloodless reduction and retention. A brochure by Brodhurst is worthy of some attention, as he claims to have succeeded in not only reducing the dislocation, but in retaining the bone in the position in which he

placed it. He advocates a subcutaneous operation preceded by weight and pulley. The result of all this is that we find ourselves in a position of uncertainty. Very young children may be successfully treated by the bloodless method, while older ones and those yet under the age of 10 must be subjected to operation. Older patients still require bone-section, practically resection of the head of the femur. We have nothing new to offer in the treatment of hip-disease, but the deformities which result therefrom have received due consideration. Osteotomy, forcible correction under an anesthetic, are still the popular methods.

In club-foot the operation on the tibia for the persistent inward rotation seems worthy of commendation, and the work of Swan has placed the operation upon a substantial basis. It will be encouraging to the general practitioner to be assured by statistical evidence that many rachitic deformities are corrected without the use of apparatus or operation—in other words, that time and growth are important agents in correcting deformity.

The advances in Orthopedic Surgery during the past year have been much greater, in our judgment, than during the preceding year. It was difficult to find in the literature of 1894–95 much that was at all new, and there were, indeed, few papers that were of much interest. In the following review we have endeavored to give, as succinctly as possible, the work which has appeared on—1. Orthopedic surgery in general; 2. Bone-pathology; 3. The diseases and deformities of the spine; 4. On the hip, both in its diseased condition and in its deformities resulting from disease and occurring at birth; 5. On the management of abscesses, chiefly those which result from diseased areas which cannot be reached well by the knife; 6. On the knee and its deformities and diseases; 7. Club-foot; 8. Deformities of the hand; 9. Deformities occurring in rickets; 10. The affections involving the muscles and tendons. A number of papers have appeared on torticollis, but we failed to find any new features in these papers.

A Definition of the Scope of Orthopedic Surgery.—Whitman[1] suggests the following definition: "Orthopedic surgery is that division of surgery which treats of disabilities and diseases of the locomotive apparatus, and of the prevention and treatment of deformities of the framework of the body." [This definition covers very fully the scope of the specialty in this country. It is to be regretted that a uniform definition cannot be adopted for America and Europe. In England the diseases of the locomotive apparatus are not included, but the deformities which result from disease are often considered by writers who somehow avoid any reference to the underlying causes of deformity. For instance, diseases of the hip and knee—indeed, of all the joints—are studiously avoided and are left to the general surgeon. It is unnecessary, however, to contend with our English brethren so long as we are unable to unite upon the scope among ourselves. The Orthopedic Association is intended to include in its membership men who employ apparatus alone, men who confine themselves almost exclusively to operative work, and

[1] N. Y. Med. Jour., June 20, 1896.

those who resort both to apparatus and to operative procedures. It is safe to say that the last-named class of men are in the majority.] Whitman very properly deals with the subject from the standpoint of both the mechanician and the surgeon, and has included, therefore, in his definition, the work which is accomplished both by apparatus and the knife. He dwells especially upon "the prevention of deformity in its broader sense, by guarding the body during the growing period from the evil effects of carelessness and ignorance, as well as unnecessary compensation for local deformity and disability."

Deformities.—Tubby[1] has a volume of 598 pages, illustrated by 15 plates and 302 figures, of which 200 are original. It is divided into 5 sections—the first treating of deformities of the spine; the second, of neck, chest, and upper extremities; the third, rachitis and the resulting deformities; fourth, deformities of the lower extremity; and fifth, ankylosis, congenital displacements, deformities resulting from cerebral and spinal paralysis, arthrodesis. The book is well written, the type is large, and the illustrations are very fair. It has much to commend it. For instance, the chapter on caries of the spine or angular deformity, while original enough, is still in thorough accord with the best teachings that relate to abscess and to compression-paraplegia. He does not use the term myelitis, because not only his experience, but his reading, has taught him that in certain cases there may be no myelitis whatever, but in every instance there is compression. He dwells very fully upon the diagnosis, and insists, not unreasonably, upon the necessity for a careful and thorough examination, with an intimate knowledge of the meaning of pains, shuffling of gait, and irregular movements. From malignant disease of the spine he differentiates with special emphasis, and quotes extensively from Marsh, who has contributed largely to both malignant disease and tubercular disease of the spine. [The treatment does not seem to be quite up to date. There are figured a number of braces that have long since been set aside as useless, and his instructions for applying the plaster-of-Paris bandage are those which were given a decade ago. On the contrary, we can heartily commend his remarks on laminectomy.] Three chapters are devoted to the subject of lateral curvature, in no one of which do we find any new points bearing upon the treatment. Indeed, all the methods are described, but the author does not commit himself to any one method, and in this, perhaps, he is wise. He, for instance, urges the restoration of the general health, recumbency in certain cases, postural methods, exercise, and supports. The chapters on both congenital deformities of the hands and fingers and on acquired deformities are unusually good; 151 pages are devoted to club-foot, and the pages are illustrated by cases in all stages of deformity. The methods of treatment are fully in accord with the teachings of the present day, and the subject itself is very fully considered. [Altogether, the author has presented a work which would be hard to duplicate. The charge cannot be brought against him that he has not made himself conversant with the current literature, and especially the current literature of this country.]

[1] Deformities: A Treatise on Orthopedic Surgery, London and New York, 1896.

Surgical Diseases of Children.—D'Arcy Power[1] has presented a very practical book, in which there is much space given to deformities and diseases of the joints; 95 pages are devoted to tuberculous diseases of the bones and joints. The work contains 60 illustrations, many of which present the deformities as well as the apparatus for correcting the same.

THE SPINE.

A New Form of Shoulder-brace.—Keetley[2] presents a very simple, and to all appearances a very efficient, shoulder-brace, shown in Figure 143. To a plaster-of-Paris or poroplastic felt corset anterior crutches are attached by a free joint a little posterior to the axillary line, midway between the axilla and the iliac crest. These crutches move very freely on the joint, and make pressure against the anterior part of the shoulder, say over the distal end of the clavicles. The force is exerted through a rubber elastic, which passes from one to the other over the back. They do not make pressure at the middle of the clavicle, where most shoulder straps do, but just at the right point—a point where one would make pressure with one's fingers if an attempt were made to hold a patient straight. They do not, therefore, press upon muscles or interfere with the action of muscles so much as one would imagine. Indeed, Keetley's argument for the use of shoulder-braces in certain forms of round shoulders, dependent, for instance, upon lateral curvature, old Pott's disease of the spine, and simple weakness of muscles in children who are too young to exercise,—this argument, we say, is very fully elaborated, and is certainly worthy of attention. He claims, for instance, that in the round shoulders of lateral curvature the leverage-power is so great that a patient cannot hold himself up, the muscles act at a disadvantage, and a little support to the shoulders is a very valuable supplement to a brace. [The orthopedic surgeon of to-day rather discourages shoulder-braces, and for reason. The muscles can be so fully developed by gymnastic exercises that the practical man takes advantage of this, and endeavors to make shoulder-supports of the muscles themselves; but when it is impracticable to give a patient correct gymnastic exercises, and when, even if one does attempt it, the patient is not sufficiently docile, then resort must be had to some artificial support. For this reason we can commend Keetley's apparatus.]

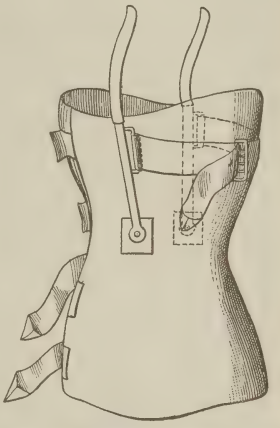

FIG. 143.—Shoulder-brace (Brit. Med. Jour., May 30, 1896).

A Spinal Brace.—Hoadley[3] describes a brace which takes its points of bearing over the sternum and over the pelvis anteriorly. No portion of the brace passes behind the body. Between the chest and the pelvic portion two lateral portions are so adjusted as to lie close to the sides, a little nearer the

[1] Surgical Diseases of Children, Philadelphia, 1895.

[2] Brit. Med. Jour., May 30, 1896.

[3] Jour. Am. Med. Assoc., Nov. 23, 1895.

posterior than the anterior aspects. The description of the brace is rather complex, although it seems simple enough, and one can get a better idea from the accompanying illustration (Fig. 144). [As to the merits of the apparatus we are not able to judge. It would seem to afford adequate support, though, like all braces, it is most efficient in the hands of the inventor.]

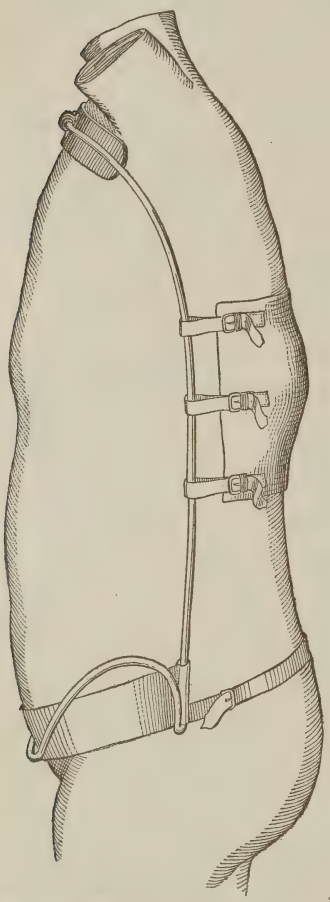

FIG. 144.—Spinal brace (Jour. Am. Med. Assoc., Nov. 23, 1895).

A Wagon with Apparatus for Pott's Disease.—Schapps[1] has published descriptions of an apparatus for the treatment of Pott's disease in the recumbent posture, which apparatus is attached to a kind of wagon. It is practically a combination of the Bradford-Cabbott frame with a wheel carriage, which enables the patient to be treated out of doors. [There is really nothing new in the device, but the details, which enable the physician to manage a case with the aid of an intelligent mother, are certainly an improvement on the ordinary methods of treatment by recumbency.]

Children's Spines.—Owen[2] contends for a close study of healthy as well as unhealthy spines in children. He insists on the necessity of giving the child the benefit of the doubt whenever one cannot tell whether the spine is normal or not. That is, the recumbent posture should be assumed until the diagnosis can be made clear. He deprecates the term "grow out" of some slight ache or discomfort. He thinks the term "growing pains" is very unfortunate. [His entire article is a plea, therefore, for early diagnosis, and this plea cannot be presented too frequently. His illustrations of the suppleness of a child's spine, the great flexibility, are especially good, and if the physician would always test the functions of the spine, errors in diagnosis would be much less frequent.]

Compression-myelitis.—Shands[3] presents brief histories of 22 cases, all of which give the final results, and all give, as well, the treatment employed, so that the statistician can easily make use of this material, and hence its mention in this article.

Cold Abscesses.—Gage[4] claims that if we can distinguish beforehand the abscesses which will disappear spontaneously and those that will not, the treatment is simple. An abscess that depends upon the tubercle-bacillus alone

[1] N. Y. Med. Jour., Aug. 1, 1896.
[2] Pediatrics, Mar. 1, 1896.
[3] Virginia Med. Monthly, 1895, p. 1165.
[4] Boston M. and S. Jour., vol. cxxxv. No. 2, p. 253.

will disappear either spontaneously or after one or more aspirations, while one that depends upon mixed infection, bacilli and other pyogenic cocci, will not, as a rule, undergo spontaneous resolution. Quoting from Dane, he says: "In pure tuberculous abscess, as in all purely tubercular lesions, leukocytosis is absent. If at any time the infection becomes mixed through the advent of pus-cocci, leukocytosis occurs. For instance, many cold abscesses of rib, hip, vertebra, etc. show no leukocytosis till opened; then the white cells rise." He concludes that if these observations are confirmed by further investigation, active interference should be postponed so long as leukocytosis is absent. He does not commit himself to the dictum, *no leukocytosis, no surgical interference,* yet we are sure that the trend of his article is in this direction. [His conclusions are fair, yet not fully in accord with the best surgical teaching of the day. To No. 4 of his conclusions we are sure the majority of orthopedic surgeons will subscribe.] The conclusions are as follows: "1. An abscess occurring in tubercular disease of the bones or joints is always secondary in importance, as well as in development, to the primary disease. Its treatment must not, therefore, in any way interfere with the treatment of the original lesion. 2. When the abscess is accompanied by any evidences of constitutional impairment, or interferes in any way by its location with the use of proper mechanical treatment, it should be immediately opened. When there is no interference with general health or with mechanical treatment, the abscess, if it presents a pure tubercular infection, may be left until it is nearly ready to open spontaneously. If it presents a mixed infection, it is to be opened at once. 3. All cases are to be opened as soon as they approach the surface to avoid unnecessarily extensive burrowing. 4. Of the methods commonly used in opening these abscesses—aspiration with irrigation, free incision with curetting—all seem to give inferior results to those obtained by simple incision in the most dependent portion, with the least possible interference with the walls of the abscess."

Shaffer[1] reports in detail 35 cases, 26 of which remained under the care of his hospital for a sufficient length of time to test the **value of** the plan of **noninterference.** Of the 26 patients, 3 had each 2 distinct abscesses, making 29 in all. In 2 of the double abscesses, large bilateral iliopsoas abscesses, absorption occurred. Of the 29, 27.58% underwent complete absorption; 65.50% opened spontaneously and closed under simple dressings in from 2 to 21 months; 6.89% were discharging a few drops daily at the time of his report; 93.09% have either closed or been absorbed. The remaining 9 are accounted for as follows: 1 was removed before treatment completed, 1 was nearly well when the patient entered the hospital, 7 had phthisis pulmonalis or multiple joint-disease or were removed from the hospital before treatment concluded. Of these 7, 5 died and 2 have small sinuses which discharge.

Wieland[2] reports on 21 **tuberculous abscesses,** with 16 complete cures treated by routine injection of iodoform in sterilized oil or glycerol, a 10%

[1] N. Y. Med. Jour., Feb. 29, 1896.

[2] Deutsch. Zeit. f. Chir., xli. 4, 5.

solution; 4 of the 21 left the hospital before recovery was complete; 1 had a fistula which would not heal and 3 months later caused septic infection; 14 of the 21 were seen again after the lapse of 2 years or more; 8 were quite well, without any return of the local tuberculosis; 1 had suffered relapse, but was cured by incision and curettage; 1 had a long fistula, but ultimately got well; 4 died 1 or 2 years after leaving the hospital—1 of tubercular trouble, 3 of amyloid degeneration. He did not omit good hygiene or medical therapeutics. Abscesses in tubercular arthritis, accompanied with grave suppuration, were most rebellious to the iodoform injections. [The method is tedious, and by reason of the long duration subjects the patient to the dangers of iodoform-poisoning.] Four cases had symptoms of poisoning, 2 of which had attacks of acute nephritis.

Bradford[1] presented a case, with autopsy, showing an abscess in front of the spinal column which pressed upon the trachea just below the larynx. For its treatment he proposed an incision down upon the tip of the transverse process at the level of the rib, removal of the periosteum from the rib, and exsection of a piece of the rib, the finger to be introduced into the opening for the purpose of exploration. On account of the larger vessels he suggested making incision on the right side. This operation he had performed in the mid-dorsal region, succeeding in draining the abscess without difficulty.

Dane[2] has studied **the blood in cases of tuberculosis of the bones** and joints, and among his conclusions he claims that a low leukocyte-count indicates the presence of an abscess, while a high count shows the presence of a secondary infection with pyogenic organisms, and in cases where at the primary operation the pus has proved satisfactory there is an increase in the leukocyte-count when the wound becomes infected.

SPECIAL TREATMENT IN CHRONIC BONE-DISEASE AND JOINT-DISEASE.

Iodoform-glycerol in Tuberculous Osteomyelitis.—Sherman[3] gives a paper on recorded experience in 20 cases—15 of hip-disease, 2 of knee-joint, 2 of ankle-joint, and 1 of elbow-disease; 164 injections were made. Half were intraarticular, the other half intraosseous, the solution being a 10% of iodoform in glycerol. In no case did he get iodoform-poisoning, nor was the injection the cause of suppuration. The action of the injections was in most instances disappointing. In no case was the orthopedic treatment interrupted. Commenting on this paper, Park had made an extensive trial of this method, but had not seen much benefit. In 2 of his cases which came to excision the iodoform was found packed into the mass, acting as a foreign body. He made culture-experiments with the iodoform, and these experiments demonstrated that the germicidal power of iodoform was very feeble. Moore said that he too had met with nothing but disappointment, except in the treatment of psoas abscess. Here he thought he had seen some benefit.

[1] Am. Med.-Surg. Bull., June 13, 1896.

[2] Boston M. and S. Jour, vol. cxxxiv. Nos. 23 and 24.

[3] Ibid., vol. cxxxv. No. 11.

Taylor stated that the iodoform and glycerol had proved disappointing, but it was his impression that a solution of iodoform and ether was valuable in sinuses. Ridlon had treated about 30 cases by intraarticular injection, one-third showing improvement; another third were stationary, and the remaining third appeared to have been made worse. Phelps had employed the treatment with negative results.

Hydrochloric Acid in Bone-diseases.—Waterman[1] has reported on 8 cases of sinuses leading to necrosed bone treated by the local use of hydrochloric acid. The acid employed was in the concentrated form, employed twice a week, the number of minims depending upon the individual case and the amount of bone exposed. These cases occurred in the Hospital for the Ruptured and Crippled, and were under daily observation. His conclusions were as follows: 1. No evil effects have resulted from its use. 2. The use of the acid in its concentrated form is preferable. 3. When the area of necrosis is extensive operative methods are advised. 4. Its action is limited to the necrosed area, whereas curetting may remove both diseased and healthy bone. 5. By the disintegration of the dead bone the newly-formed tissue has a better opportunity for its more rapid development.

Dry Heat of High Temperature.—Wirt[2] describes an apparatus which he has employed for the treatment of diseased joints consisting of a copper drum, 12 in. long and 9 in. in diameter, fitted at each end with a wooden ring and a hood of thick rubber. The back of the knee is protected with cotton after it is enclosed in the apparatus, and it is applied to the outside by means of a Bunsen burner. The majority of his patients tolerated a temperature between 250° and 300° F., provided 3 holes were made in the drum to secure proper ventilation and keep the air dry. It is claimed for this treatment that immediate relief to pain ensues and the mobility of the joint is temporarily increased.

THE HIP.

Congenital Dislocation.—Whitman[3] calls attention to the cure one may expect from the **Hoffa-Lorenz operation.** It is not an immediate perfect result, or even, so far as one can judge, a remote perfect restoration of function. [This accords with our own experience, and leads us to say that if one does not expect absolutely perfect results the operation may be of great value.] Hoffa[4] has presented a specimen obtained from a 3-year-old child dying of diphtheria after complete recovery from his operation. The pelvis showed that a good joint had been formed. The new acetabulum, which was soft and spongy when he operated, was found covered with a complete layer of hyaline cartilage.

Bloodless Reduction.—Mikulicz[5] attaches little importance to any malformation of the head or acetabulum in very young patients, claiming

[1] N. Y. Med. Jour., Aug. 8, 1896.
[2] Boston Med. Jour., Sept. 10, 1896.
[3] Med. Rec., vol. l. No. 11, p. 361.
[4] Am. Med.-Surg. Bull., 1896, ix. p. 97.
[5] Arch. f. klin. Chir., Bd. xlix. H. 2.

that at this period the head fits well into the acetabulum. The acetabular changes and those in the head take place during growth. He and Shede believe that in patients who have not walked replacement and retention are quite possible. Even taking into account the difficulties of cure—(1) shortening and retraction of muscles; (2) shrunken condition of the capsule or narrow opening into the acetabulum; (3) difference in size between head and acetabulum; and (4) hypertrophy of ligamentum teres—the slow method of reduction in these young patients will overcome all these difficulties. The apparatus he employs consists of 2 boards, extending from the buttock to the foot of the bed, united above, and so arranged that the lower ends can be supported. The legs are fastened to these and are abducted by means of the lower ends. He makes provision also for rotation and extension. He thus secures extension, abduction, and outward rotation. His patients are not confined to the apparatus all the time, but he at first applies it for 10 or 12 hours at a time. In the intervals he employs a corset to make pressure over the trochanters. Five cases are cited, 3 of which were entirely cured in 12, 17, and 18 months. He claims that the head was in the acetabulum and that the gait was normal. Ages, 1, $3\frac{1}{2}$, and 4 years respectively.

Reduction of Dislocations of the Hip.—Allis[1] has published a most valuable inquiry into the difficulties encountered in the reduction of dislocations. The brochure contains 171 pages, composed of reminiscences which deal with 2 or 3 very interesting cases wherein the most skilful surgeons failed: Part I. an introductory study, which deals with the anatomy, supplementary work, and a nomenclature; Part II., reduction of dislocations by manipulation, wherein the methods and obstacles are critically examined. His nomenclature is based upon the "firm conviction that all conceivable dislocations are primarily either inward or outward, and that from these primary positions the head may be secondarily shifted to any point about the socket within reach of the remnants of untorn capsule that join the shaft to the rim of the socket." He would denominate the primary inward as the thyroid, the primary outward as the dorsal. The thyroid he would subdivide into the low, middle, and high thyroid, and the dorsal into the low, middle, and high dorsal. He rejects the names "sciatic," "spinous," "interspinous." "As the head can closely approximate positions described by authors as 'subspinous,' 'interspinous,' or 'spinous' from either plane, if the names are to be retained I would suggest the prefix thyroid or dorso." [The methods of reduction are very clearly illustrated, and we make mention of this valuable work as a supplement to orthopedic surgery. The lesions about the hip are so varied and so complicated that it is necessary for one accomplished in this specialty to become familiar with all the lesions that can possibly arise in or about the hip.]

Treatment of Ankylosis.—Lorenz[2] adopts an open method, through an incision about 5 or 6 cm. in length in the long axis of the femur, begun at a point over the trochanter. The incision is carried through the gluteal mus-

[1] The Samuel D. Gross Prize Essay, Philadelphia, 1896. [2] Berl. Klinik, June, 1896.

cles, parallel with its fibers, in order to free everything between the head of the femur and the pelvitrochanteric line. A wide chisel is now inserted between the head of the bone and the pelvis, but the periosteum is not separated. While the chisel is still in position an assistant should over-adduct the thigh, so as to favor the passage of the chisel into the socket. He aims, therefore, to divide all the adhesions. The limb is brought by means of traction and manipulation into the corrected position, and retained by means of a plaster-of-Paris spica. Perineal straps are employed. At the end of 4 or 5 days the patient is allowed to get up and go about, using a cane. At the end of 5 or 6 weeks the plaster from the knee down is removed, and a short spica is allowed to remain for about 2 weeks longer. At the end of this time the limb seems to be as firmly ankylosed as at first, but after it becomes less sensitive one will perceive a certain amount of flexion and extension. The author forbids all attempts at passive motion, but active motion is encouraged. The surgeon should encourage this from day to day and put the patient through active movements, a little later assisting by passive movements. His after-treatment he terms the "gymnastic after-treatment." As illustration, the patient is to lie at first on his abdomen, and, with from 5 to 20 lb. weight over his hips, allow the limb to swing in the air. This is to gradually increase the flexion. The reverse for extension. Where there is perfect bony ankylosis he advises that an osteotomy should be done through the intertrochanteric line. If only the neck remains, chisel through this.

Rarity of Juxtaarticular Tubercular Ostitis.—Menard[1] believes that this is rare in the region of the hip, from a very large experience at the hospital at Berk, where he was able to find only 5 cases.

Atmospheric Pressure.—Querken[2] is unable to verify the theory of the Weber Brothers that atmospheric pressure keeps the bones of the hip-joint in contact. He has made a number of investigations bearing on this point, laying bare the large trochanter, severing the sources of the muscles at their attachment, and employing weights attached to the femur for the purpose of separating the head of the femur from the acetabulum. Traction of a light weight was not sufficient to draw the head of the femur out of the socket. He estimates the pressure of the synovial fluid in the hip-joint as from 4 to 10 mm. of mercury while the joint is in a state of rest. He endeavors to controvert by clinical facts Weber's theory, citing as illustration cases of infantile paralysis and nontraumatic dislocations of the hip.

The Best Osteotomy for Vicious Ankylosis.—LeDentu[3] prefers the cuneiform excision, because he believes that the shortening can be still further overcome by continual extension. [We disagree with the author from a personal experience, and believe that the oblique section is preferable.]

Models for Measuring the Deformity.—Judson[4] has an attractive paper describing certain models which he has employed for estimating the

[1] Rev. d'Orthop., Sept. 1, 1895, p. 326.
[2] Ibid., May, 1895, p. 223.
[3] Ibid., Mar. 1, 1895.
[4] Am. Med.-Surg. Bull., Feb. 22, 1896.

angle of deformity. The advantage of these models, which are made of cardboard and so constructed as to give lordosis and free movements at the hips, limited at any given point by an ordinary scarf retainer, is that they enable one to measure lateral deviation as well as flexion and extension. The author claims for them great help in the class-room.

A Hip-splint.—Vance [1] attaches to a leather fixation-splint a stem which passes below the foot, by means of which traction can be made. [The author claims excellent results from this method, and those who are familiar with his work readily assent, because he is an expert mechanician, gives much personal attention to his cases, and especially to the fit of the apparatus. Other surgeons have failed to get the same good results from the use of leather.]

THE KNEE.

Synovitis.—Hoffman [2] has obtained good results by the use of adhesive strips applied over the joint, but not completely encircling the limb. In looking up the history of the use of adhesive plaster he has found that Peter Hood, an English bonesetter, used the adhesive strips, such as are employed in the Cotterell dressing for sprained ankle, as early as 1848. [As one of the authors has given credit in former publications to Cotterell of London, he begs now to acknowledge his indebtedness to Hoffman for calling his attention to the reference to Hood's treatment. His son, Wharton Hood, in his book on bonesetting [3] quotes from his father's article on the treatment of sprained ankle, which was published in 1858, as follows: "This feeling made me resolve to adopt the following course of treatment—namely, to strap the whole of the foot and ankle over with adhesive plaster and then cover this with a bandage." . . . . "I put the plaster evenly over the foot and ankle and then applied a bandage moderately tight. I drew on my stocking, and, to my delight and surprise, I was at once able to walk across the room without any pain, and continued throughout the day as long as I did not twist the foot, but kept it perfectly straight and flat when I placed it on the ground." It may be mentioned that the patient himself was Peter Hood. Furthermore, that the result was excellent—that he sprained the same ankle 5 years later, strapped it after a day or two of antiphlogistic treatment, securing very promptly an excellent result, which continued up to the date of his publication, 5 years later.]

Excision as an Orthopedic Procedure.—Plimpton [4] analyzes 65 cases wherein excision was performed as an orthopedic measure. The gross pathologic appearances are illustrated. The average shortening in 57 cases was a little less than 1 in., the least shortening $\frac{1}{2}$ in., greatest shortening 3 in.; 1 patient died from too much ether, 1 died 3 months after the operation, sarcoma appearing in the knee. [The article really is published, so far as one can judge from reading it, to demonstrate the rapidity with which the operation can be done. For instance: "The average time of operation in the

[1] Med. News, Aug. 29, 1896.
[2] Am. Med.-Surg. Bull., Oct. 1, 1895.
[3] Macmillan & Co., 1871, London and New York, p. 103.
[4] Med. Rec., Jan. 25, 1896.

last half of this series will not exceed 14½ minutes, save in an exceptionally bad case." A criticism has been offered by members of the Orthopedic Section, as well as the Surgical Section of the Academy, that the operation cannot be done thoroughly in that length of time. Indeed, the wisdom of attempting it is questioned. The reason given by the author is a good one—namely, the patient is less apt to get overdosed with ether.]

Bony Ankylosis.—Marsh[1] states that his opinions have materially changed with regard to the cause of bony ankylosis; that is, he formerly believed that suppuration was the only cause. Suppuration is not necessarily followed by ankylosis; and, indeed, this condition occurs often independent of suppuration. It occurs in tuberculosis without pus, in Charcot's disease, after nerve-injury, in gout and rheumatism, in gonorrhea, occasionally after trauma. He has observed it in extreme cases of lateral curvature and in osteoarthritis. He states, furthermore, that he knows of no means by which bony ankylosis can be averted in osteoarthritis, and is quite sure that passive movements cannot prevent it. When bony ankylosis does occur, he advises excision or osteotomy.

Death after Forcible Straightening.—Ahrens,[2] from Bruns' clinic, reports a death due to fat-embolism of the lungs. The patient was 53 years of age. The ankylosis had existed for a long time, and attempts at gradual correction had failed. Two days after the operation for forcible straightening drowsiness came on, and death followed next day. The autopsy showed the fat-embolism in the lung, the ends of the bones in an advanced stage of osteoporosis, and 2 recent crushes. He referred to analogous cases reported by Halle and Marburg.

Brisement Forcé.—Townsend[3] reports in detail 11 cases of ankylosis in which *brisement forcé* was employed, in many instances repeatedly. The cases were all rheumatic. His results were as follows: 1 complete cure when the shoulder was involved, 1 partial, but in this case *brisement forcé* was only employed once. There were 9 failures. He further concludes that one must be sure that no active disease exists at the time of the operation, and that the intervals between the operation should be given to massage, electricity, douches, and other similar measures.

Slipping Patella.—Bradford[4] reports 7 interesting cases in which the patella had become dislocated. In none of his cases was there any noticeable lengthening of the ligamentum patellæ, mentioned by Shaffer. Lack of tonicity of the extensor cruris muscles, especially the lower fibers of the vastus internus, and a laxity probably of the internal lateral ligaments, seemed to be the causes in the cases reported. He discusses the mechanical means employed —massage and electricity and operative measures. The operative treatment is easy of execution and free from danger. The procedure which he prefers is taking a fold in the capsule, while the transplantation or shortening of the ligamentum patella will not be found necessary except in the severer cases.

[3] Med. News, Feb. 1, 1896.
[4] Boston M. and S. Jour., Feb. 20, 1896.

General Pathology of Bone.—Spencer[1] deals fully with the comparative physiology and embryology of bone, the effect of alterations in the circulation of the blood through bone, on nerve-influence, on changes due to impairment of general nutrition, and the new formation of bone. Among his conclusions are the following: A full normal supply of blood favors normal bone-formation. An excessive arterial supply leads to decalcification and absorption. A diminished supply checks the normal rate of bone-formation, and "eccentric atrophy" is the result. An excessive supply of venous blood causes pathological bone-changes. The nerve-influence is regulatory in action. There are other important conclusions drawn from these lectures that are well worthy of study.

Acute Infectious Disease.—Park[2] deals with the deformity and malformations which result from acute infections. In this he states that "necrosis forms by all means the most common result of osteomyelitis. Inasmuch as this produces weakening of the bone, fracture, deformity, or curvature may result." Incidentally he mentions that Volkmann collected 32 cases in which epitheliomatous changes occurred in the site of old fistulous passages.

Tuberculous Disease of Bone and Joints.—Cheyne[3] has embodied in a volume of 361 pages a valuable treatise on pathology, symptoms, and treatment. The chapters on the synovial membrane and bone are of especial interest to the orthopedic surgeon, and are based upon the author's Astley Cooper's prize essay. Operative procedures are not recommended to the exclusion of mechanical appliances, yet as a matter of course the latter do not occupy a very important place in the volume. [To one whose attention is devoted almost exclusively to mechanical orthopedics this book is of especial value, as it deals with the life-history of the tubercle, the localities in which it may be frequently found, and the influence of various agents employed for its relief.]

Loose Bodies in Joints.—Barth[4] has studied histologically 24 specimens, all due to a chipping off of a portion of the joint-surface or to arthritis deformans. The osteochondrosis desiccans theory of König was not susceptible of proof by pathologic anatomy. A cartilage-body may be torn out by undue tension of the crucial ligament, and yet very slight joint-symptoms follow. Signs of foreign body appear later, after many months, or years even. Curiously enough, the experiments on animals showed that the cartilage thus broken off remains alive, while the bone dies. The observations are interesting, because one should be able to make accurate pathologic diagnoses, and with this knowledge secure union at or very near the point of detachment, or, failing in this, to remove through an incision the offending portion.

Bolton[5] has analyzed 72 cases. His paper is full of interest, inasmuch as the different structures of these bodies have been noted, the postmortem findings in a few cases are recorded, and final results are given. He has no hesi-

[1] Lancet, May 30, 1896.

[5] N. Y. Med. Jour., June 27, 1896.

tation in recommending, from his exhaustive study, removal of the body when there is much disability.

Arthritis Deformans.—Osler[1] has placed on record 2 or 3 cases occurring in children. In 1 advanced case, a child 7 years of age, death occurred from intercurrent nephritis. The autopsy showed extensive involvement of the cervical vertebræ. He regarded this complication as exceedingly rare. [From our own experience the involvement of the cervical vertebræ is not so rare, as a number of cases have been under observation during the past 15 or 20 years at the Hospital for the Ruptured and Crippled. Very few have been placed on record, for the reason that they were so rebellious to treatment].

Koplik[2] presented quite an elaborate history of a case in a child 7 years of age. A very good bibliography is attached to his paper. [Unfortunately, however, there is little in the way of treatment that is worthy of record.]

Bier's Treatment.—Meyer[3] has made a report on 2 or 3 cases of tubercular joint-disease treated by the method of Bier. The idea in this treatment is that chronic hyperemia might favor resolution in tuberculous lesions. Meyer has found it valuable even after operations, and is firmly convinced that it is an excellent thing for obstinate sinuses. He insists that the patient must remain under observation for a considerable time, so that an acute or cold abscess, if it develops, may be recognized and treated early. The bandage he applies in a slightly different place from time to time, that atrophy of the muscles may be avoided. In children it should be applied quite lightly at first, in order to gain confidence. The parents are instructed to leave the bandage on as long as possible, say a half hour or as long as it is tolerable. After its removal massage is to be employed; then the bandage again. Pretty soon it can remain on day and night, to be removed morning and evening only for massage. The part of the extremity below the affected joint should be surrounded by a snugly-applied flannel bandage. [The treatment of itself is certainly commendable, but the danger seems to be in the confidence one may place in it to the neglect of protection apparatus. We are prepared to welcome any treatment that will assist in the cure of obstinate sinuses, and if hyperemia will contribute to this, it is certainly worthy of consideration. From a limited experience in hospital with tubercular ankles we are convinced that hyperemia has done very little in the way of effecting relief.]

CLUB-FOOT.

Inward Rotation.—Swan[4] proposes a new operation for the cure of inward rotation of the entire limb after aggravated equinovarus. He makes a section of the tibia at the junction of the middle with the lower third, carefully dividing it transversely. The section must be complete. The fibula is left intact, while the two segments of the tibia are firmly grasped, the lower one being rotated outward. This procedure carries with it the foot and the

[1] Mont. Med. Jour., 1896, vol. xxiv. No. 10.
[2] Arch. of Ped., Mar., 1896.
[3] Am. Med.-Surg. Bull., Jan. 25, 1896.
[4] Dublin J. M. Sci., Oct., 1895.

fibula. He closes as follows: "In these days of rigid surgical cleanliness the patient after such an operation should suffer neither pain nor inconvenience, and in a short time will be running about with symmetrical and unfettered limbs. I have operated on many dozens of cases by this method, and in the great majority of cases of aggravated equinovarus I believe it will be found a satisfactory and necessary proceeding."

Ridlon[1] has a memoir which deals quite fully with the modern treatment of club-foot, which is well illustrated, and which shows the Ridlon operation, which is practically a modification of the Phelps method. [For one who cares to see all the different methods well illustrated, the appliances employed, etc., we would urge him to consult this paper.]

Sayre[2] contrasts the results of removal of the astragalus with forcible manipulation in the treatment of talipes varoequinus. His comparison is rather in favor of the forcible manipulation. Although the foot not operated upon except by manipulation was the better foot of the two, he still was dissatisfied with the result, and made a cuneiform osteotomy of the tibia and fibula above the ankle-joint. In conclusion, therefore, he advocates in proper cases the removal of a wedge of bone from the tibia and fibula in preference to tarsectomy.

The *x*-Ray.—Barwell[3] and Willard[4] have published various forms of talipes as depicted by the *x*-ray. They are not very clear, and do not give us any more information than an ordinary picture of a skeleton foot would give. In one of Barwell's, however (p. 235), a very good illustration of the distortion of the os calcis and the extreme arching of the midtarsal region is shown in a case of calcaneus.

PARALYTIC DEFORMITIES.

Goldthwait[5] has placed on record a very interesting series of cases where the operation of **tendon-transplantation** has been performed, and Samuel Milliken[6] has published a single case in which he claims priority. This has been disputed by Benjamin Parrish, whose contribution was on record long before the date of Milliken's operation. Indeed, the members of the Orthopedic Section of the Academy have a very distinct recollection of Parrish's case, presented a few years ago. Goldthwait concludes as follows: "The best results are to be looked for in the cases in which one group of muscles is paralyzed, leaving the antagonistic or accessory group unimpaired." Much of the deformity is due to the action of these muscles without the control of the other group; 4 cases are reported after at least 3 months since the operation. The first case, that of an adult, was operated upon over a year ago. In all there has been a marked improvement. In 3 cases the peroneus longus was attached to the tendo Achillis and the peroneus brevis to the flexor longus pollicis. In 2 cases the anterior tibial tendon was attached to the peroneus

A Manual of Obstetrics.

BY

W. A. NEWMAN DORLAND, M. D.,

Assistant Demonstrator of Obstetrics, University of Pennsylvania, etc.

760 Pages, with 163 Illustrations in the Text, and 6 Full-page Plates.

PRICE, $2.50 NET.

This work is a systematic and rational presentation of the subject of Obstetrics as recognized by the leading teachers of the day. The subject has been divided into the two main parts, *Physiologic Obstetrics* and *Pathologic Obstetrics*. Prominent features of the book will be found to consist of the large number of *diagnostic tables* that have been formulated and introduced in their proper places; the classification of puerperal sepsis; and the grouping of the hemorrhages of pregnancy, of the puerperium, and of the newborn.

For Sale by all Booksellers, or sent post-paid on receipt of price.

A MANUAL
OF THE
PRACTICE OF MEDICINE.

BY

GEORGE ROE LOCKWOOD, M.D.,

Professor of Practice in the Woman's Medical College and in the New York Infirmary; Attending Physician to the Colored Hospital and to the City (late Charity) Hospital; Pathologist to the French Hospital, etc.

935 Pages, with 75 Illustrations in the Text, and 22 Colored and Half-Tone Plates.

PRICE, $2.50 NET.

This manual presents the essential facts and principles of the Practice of Medicine in a concise and available form, adapted to meet the requirements of those who heretofore have been obliged to resort to larger works of reference.

For Sale by all Booksellers, or sent post-paid on receipt of price.

W. B. SAUNDERS, Publisher,
925 Walnut St., Philadelphia.

SECOND EDITION, REVISED.

A Manual of Medical Jurisprudence and Toxicology.

BY

HENRY C. CHAPMAN, M. D.,

Professor of Institutes of Medicine and Medical Jurisprudence in the Jefferson Medical College of Philadelphia; Member of the College of Physicians of Philadelphia, of the Academy of Natural Sciences of Philadelphia, of the American Philosophical Society, and of the Zoological Society of Philadelphia.

With 55 Illustrations, and 3 Plates in Colors.

PRICE, $1.50 NET.

For many years there has been a demand from members of the medical and legal professions for a medium-sized work on this most important branch of medicine. The necessarily prescribed limits of the work permit only the consideration of those parts of this extensive subject which the experience of the author as coroner's physician of the city of Philadelphia for a period of six years leads him to regard as the most material for practical purposes.

For Sale by all Booksellers, or sent post-paid on receipt of price.

A MANUAL OF ANATOMY.

BY

IRVING S. HAYNES, M. D.,

Adjunct Professor of Anatomy and Demonstrator of Anatomy, Medical Department of the New York University, etc.

Beautifully Illustrated by 135 Half-Tone Illustrations Reproduced direct from Photographs of Dissections taken by the Author.

12mo. CLOTH. PRICE, $2.50 NET.

The author's experience as a teacher of anatomy for a number of years has peculiarly fitted him for the preparation of a book such as this. The text is thorough, comprehensive, and concise. Special attention has been given to the viscera and their relations to the surface of the body, on account of the practical importance of such knowledge to the student. The book is handsomely illustrated, there being, in addition to the 135 half-tone illustrations, 42 diagrams, representing in outline the more intricate plates, and thoroughly bringing before the student the points which similar works have failed to elucidate.

For Sale by all Booksellers, or sent post-paid on receipt of price.

925 Walnut St., Philadelphia.

tertius. The tendons were attached by splitting one and drawing the other through this and suturing them with quilted sutures.

Arthrodesis.—Karewski[1] gives his results in the operation known as arthrodesis. The 3 pathologic conditions which he claims can be overcome by this operation are shortening of the extremity, contraction of the joint, and flail-foot. It is done as a last resort. He finds it more serviceable in the ankle-joint or tarsus, though he has done the operation twice in monoplegia of the arm. His test for the benefits that may be derived from the operation is a simple one—namely, to put the foot in plaster of Paris and see how the patient gets about with it. In 9 patients operated upon, 7 used crutches before the operation, while afterward all of them could walk by simply using a cane. He states that, as the interval from the time of operation increases, just so much better becomes their condition as regards walking. Greater success is met with in children than in adults. In 1 of his cases necrosis of the calcaneus occurred, due to circulatory disturbance, and a partial resection of the joint was necessary to save the foot. He has done the operation in some cases of hammer-toe. [From our own personal experience in this procedure we are convinced that it has a very useful field. It is possible to make a flail-foot, even if one does not secure perfect synostosis, much more useful. The great difficulty in getting the best results is that the operation is usually confined to the tibio-tarsal joint, while the mid-tarsal joints are free, and, as the strain is thrown upon the foot at this point, the bony adhesions are sometimes broken down at the tibio-tarsal.]

HAND AND FINGER.

Cleft-hand.—Dowd[2] has placed on record a case successfully treated by the use of periosteal flaps. He has a very good Röntgen picture which shows congenital fusion of the 4th and 5th metacarpal bones. The pictures of the hand before and after operation show conclusively the value of the operation (see Figs. 145, 146).

Clasp-knife Finger.—Buedinger[3] relates the case of a woman aged 68 who fell with the thumb of her outstretched right hand abducted. Soon thereafter violent pain occurred in the neighborhood of the metacarpophalangeal joint, without swelling. Marked crepitation on movement of the finger was noted. A few months later pain gave place to an impairment of the flexion and extension of the joint. She noticed that active extension of the flexed thumb had become impossible, but that when she threw the last joint back forcibly with the other hand, the obstruction to extension gave way with a sudden snap. He found slight rheumatoid changes in the joint. Flexion of the thumb was nearly perfect, but caused at the base of the first phalanx a hard, painless mass, above which the skin was freely movable, and which could be felt to disappear with a sudden extension of the joint. On incision he found the swelling to be that of the tendon sheath folded up like a concertina

[1] Berl. klin. Woch., Sept. 23, 1895. [2] Ann. of Surg., Aug., 1896.
[3] Wien. klin. Woch., May 21, 1896.

during flexion, and it caught the tendon so tight that it could only be released by a smart tug. The fold of the sheath contributed to the temporary swelling. The sheath was divided and tucked over, when the mobility of the joint

FIG. 145.—Cleft-hand treated by periosteal flaps: appearance before operation (Ann. of Surg., Aug., 1896).

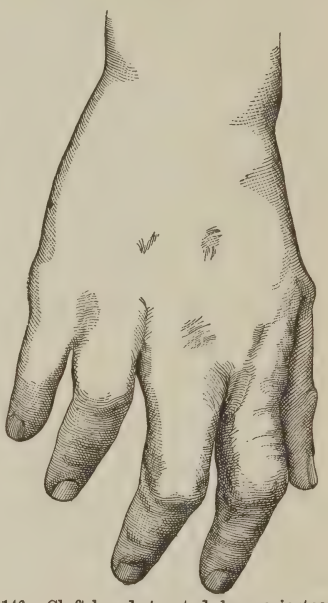

FIG. 146.—Cleft-hand treated by periosteal flaps: appearance after operation (Ann. of Surg., Aug., 1896).

was perfectly restored. In a study of this affection the author finds that the cause is by no means uniform, as it is often attributed to abnormalities in the tendon as well as in the sheath. He advises the open method by way of treatment.

MUSCLES AND TENDONS.

Marsh[1] gives a very interesting clinical lecture on the **displacements and injuries** of muscles and tendons. It is well illustrated, and deals pretty thoroughly with the displacements which one is apt to encounter. He does not commit himself to the open method of treatment, for the reason that in rupture of the tendo Achillis, for instance, union very often takes place if the severed ends are placed sufficiently close to each other. When a fleshy part of the muscle is torn he believes that attempts to unite the ends by suture would be useless, as the sutures would not hold; but when one can get the sheath of the muscle and bring the severed ends together, much good may result.

ACHILLODYNIA.

Roessler[2] presents a paper which is fully abstracted in the American Medico-Surgical Bulletin for March 28, 1896. The Achillo-bursitis anterior is the

[1] Brit. Med. Jour., July 25, 1896.

[2] Deutsch. Zeit. f. Chir., xlii. No. 5.

name the author gives, based upon an analysis of 10 cases. He shows by diagram the normal bursa in front of the tendo Achillis, and, having examined 225 of these bursæ, has seldom found them perfectly normal. In such as presented symptoms he found thickened walls, periosteal hypertrophy, with hyaline degeneration. Indeed, such changes existed as would occur from long-continued rubbing and irritation.

RACHITIC CURVES.

Spontaneous Cure.—Veit[1] had proved, by photographs taken in 1891 of a number of curves in rachitic children, and again in some patients 2 or 3 years later, that a spontaneous change for the better is the rule. [It all depends upon the growth. We can from our own general experience substantiate the claims of Veit.]

Bruns[2] has made similar observations at the Tübingen Clinic, and gives his conclusions as follows: 1. The greatest number of cases undergo spontaneous cure; 2. The process of spontaneous cure lasts from 2 to 4 years; 3. If the curves are unchanged at the sixth year, spontaneous cure does not occur; 4. The chief aim of the treatment is to improve the general health. Of the number of cases which he has observed, 75% were cured, 1.53% were improved, and only a little over 9% remained in statu quo. He believes that after the acute stage it is not detrimental for the children to be on their feet.

OPHTHALMOLOGY.

BY

HOWARD FORDE HANSELL, M. D., AND WENDELL REBER, M. D.,

OF PHILADELPHIA. OF PHILADELPHIA.

General Epitome.—Although there has been no startling advance in ophthalmology during the past year, our lines of positive knowledge have been steadily pushed farther into the debatable territory. In **anatomy** we have come to know much more fully the intimate nature of the retina, thanks to the latest silver and gold methods of staining. One investigator traces accurately the light-impression, while another pronounces the sensation of sight as the result of a pressure-stimulus taking place within the goblet (pigment) cells. While speaking of the retina we might note the disposition on the part of some to class glioma of the retina among the sarcomata. **Trachoma** has come in for its usual full discussion, finding advocates for both the chemic and the mechanic treatment of the granules. Inasmuch as trachoma is a condition almost sure to terminate in a certain degree of conjunctival atrophy, it would seem that surgery ought to be reserved for the final "coup." **Sympathetic ophthalmia** has proved quite a battle-ground, and there is a growing consensus of opinion as to the inadequacy of Deutschman's migration-theory. Unfortunately, this relegates sympathetic ophthalmia to its position of 10 years ago. Attempts are again being made to trace the path of the irritation. As to **glaucoma,** the question remains in statu quo. The clinical fact seems to stand that, no matter what the exact nature of the originating cause may be, retention is the final expression of that process. The therapy of glaucoma is somewhat better defined by several exhaustive clinical studies.

Two corneal conditions have been extensively investigated: **ulcus corneæ serpens** and **keratitis interstitialis.** The former has been pretty conclusively traced to the pneumococcus or Fränkel-Weichselbaum bacillus, and the necessity for early vigorous measures is emphasized. **Parenchymatous keratitis,** it is claimed, is not so often evidence of hereditary syphilis as Hutchinson would have us believe. It is instead thought to be not infrequently tuberculous. The literature of **orbital tumors** has been quite enlarged, and we are glad to note an effort toward a better classification of orbital new-growths. The intractability of orbital syphilis is pointed out.

To perform **iridectomy** or not is still the question with cataract-operators. After sifting all the evidence we are more and more persuaded that

the preference for one or the other method is largely a matter of personal equation. The latest statistics would show that the average visual acuity is slightly better after the simple operation, yet it must be borne in mind that at times nothing deceives better than figures.

The eye in its relation to systemic diseases continues a fruitful field for the broad-minded investigator. One worker shows that the average duration of life after the appearance of albuminuric retinitis (save that of pregnancy) is 2 years. The widespread influence of gout on the eye is graphically set forth, and the almost invariable association of greatly lowered nutrition with idiopathic cataract reemphasized. Iritis is shown to be more frequently secondary to systemic conditions than is commonly believed.

The year has brought forth an avalanche of evidence to the effect that no department of preventive medicine is more important than the correction of **anomalies of refraction** and of muscular action. Doubt must give way before the brute force of such an array of facts. If permitted to continue in the child and youth, eye-strain means neurasthenia, etc. in the adult. The importance of the fact cannot, therefore, be overestimated. In all functional nervous diseases careful research into the condition of the intraocular and extraocular status, by a skilful oculist, cannot be too strongly advised. The pendulum is slowly but surely swinging away from the operative treatment of imbalance of the eye-muscles, the more rational gymnastic methods supplanting the surgical ones. The innervational method of increasing adductive power is rapidly gaining favor. The relative value of advancement and tenotomy as a combined measure in squint is graphically shown by an exhaustive study of over 600 cases.

Among **new remedies** formol seems to stand out as the most favored. Subconjunctival injections are not as popular as they were a year ago. Arecolin is added to our group of myotics, and iodol, ichthyol, rhinalgin, etc. have found a place in our therapy.

The most interesting **new instruments** of the year are a portable ophthalmometer and a prismatic perimeter.

The application of the **Röntgen rays** to ophthalmology in the detection of the precise site of foreign bodies in the anterior section of the ball has been practically demonstrated, and, in our opinion, it is only a question of a few months before their use will be extended to the diagnosis of foreign bodies in the vitreous. In fact, the practicability of this method has already been personally suggested to us. If a plate encased in a protective rubber shield is inserted far up into the nostril, and the Crookes' tube held close to the temple on the same side, it has been found that the blade of a Graefe knife that has been thrust through a fresh animal's eye imbedded in the human orbit, corresponding closely to the conditions obtaining in life, will be found pictured in its entire length after a few minutes' exposure, since the rays are transmittable through the thin plates of bone of the orbit and nose. By these means the presence, the approximate location, the shape, and size of a piece of metal can be positively determined before operation.

CONGENITAL MALFORMATIONS.

Normal Growth of the Eyes.—Weiss[1] measured accurately the eyes of new-born children and of adults at different ages, and found that the volume of the eyes increases from 3 to 4 fold during lifetime, the volume of the whole body 21 fold. The eyes grow at the same rate as the brain, and equally in all directions.

The Cornea.—A child 3 days' old died of pneumonia. Teplyachine[2] examined the cornea and uveal tracts, and found both were infiltrated with gummatous cells throughout their depth, showing conclusively intrauterine disease of both eyes of syphilitic origin. A congenital dermoid cyst was removed from the cornea by Brose.[3] There was also lack of development of the right side of the face.

Stephenson[4] has seen in the cases of 2 brothers **total absence of the iris** without other anomaly. Duboys[5] had a case of double congenital aniridia without other abnormalities.

Corectopia, according to Van Duyse,[6] originates in an abnormal formation of the vascular coat of the embryonic lens and in an incomplete absorption of the pupillary membrane.

The Lens.—Tiffany[7] observed 2 cases of ectopia lentis that occurred in a family of 9 children; 5 other children and the father had the same anomaly. All the children were hyperopic. Congenital aphakia, coloboma of the choroid near the disk, and an opaque body extending to the capsule from the disk coexisted in an eye examined by Dunn.[8] Piecola[9] reports a case of **persistence of the canal of Cloquet,** with remains of the hyaloid artery. The unusual coincidence of a **persistent hyaloid artery,** a persistent pupillary membrane, and a subconjunctival venous angioma is noted by Moll.[10]

Congenital night-blindness may exist without the ophthalmoscopic signs or the symptoms of retinitis pigmentosa. It is a distinct disease or condition depending upon the malnutrition of the deep layers of the retina. In the cases reported by Cutler[11] the disease was transmitted through the males only of 5 generations.

The Lids.—Congenital entropion of the upper lids was recorded by Harlan.[12]

The Orbit.—Lagrange[13] removed, with fatal result, a large congenital glioma of the orbit from a child 20 days old. Gallenga[14] has discovered congenital nodules of cartilage in the orbital tissue. In exploring the site of a dermoid tumor of the orbit that he had emptied of its contents Doyne[15] found the outer wall of the orbit was missing.

Nystagmus.—Adenoud[1] and Benton-Fanning[2] record instances of horizontal nystagmus associated with arhythmic horizontal oscillation of the head that ceased during sleep and diminished by will. Treatment was of no avail. The family history of the affection extended through several generations.

Hydrophthalmus.—Angelucci[3] believes that hydrophthalmus is a consequence of heart-disease, and should be classified as a vasomotor disturbance. Lodato[4] has made clinical observations to prove the uselessness of iridectomy in the treatment of congenital hydrophthalmus.

Lacrimal Apparatus.—Stephenson[5] reports the single instance in literature of a congenital duplication of the caruncula lacrimalis.

AMETROPIA, ITS CORRECTION, SEQUELS, ETC.

Size of Test-letters.—Grove[6] draws attention to the important fact that there is a difference in the size of Snellen's test-types as sold by different opticians. He has frequently measured them in private offices and in hospitals, and found them usually wrong. His observation is that the types are too large, and that this is the fault of the printer, but it will produce errors too great to be ignored in practice. [This is a matter that should be attended to. But the fault lies not wholly with opticians. Oculists are constantly authorizing the publication of test-cards regardless of Snellen's sizes.]

Beaumont[7] urges more definite regulations with regard to the question of **latent hyperopia** in the examination of candidates for public service. He points out the fallacy of assuming that vision of $\frac{6}{6}$ necessarily indicates emmetropia. [The same observation applies to the United States military and marine service. It should not be forgotten that statistics are valueless in which the tests have not been made under mydriasis and with the test-lenses. This also applies to the testing of the eyes of school-children.]

Ingalls[8] pleads for **the early correction of ametropia,** declaring that "it is a waste of time to send a child to school when his eyes are not in proper condition to do the work assigned." [This language is not one whit too strong. We have often felt the profoundest pity for children who, handicapped by an ocular defect, have been goaded by teacher, schoolmates, and parents into nervous collapse.]

Reflex Symptoms.—Jessup[9] reiterates the well-known fact that persistent and recurring headaches in young persons and in those near the presbyopic age are in many cases due to an error of refraction, weak accommodation, and anomalies of the extrinsic muscles. Mittendorf[10] reports 4000 cases of headache that were relieved by the correction of optical defects. In 50% of the cases the ametropia consisted of very low degrees of hyperopic astigmatism. Simple myopia[11] rarely plays an important role in the etiology, but

[11] Jessup, loc. cit.

myopic astigmatism is often a cause. The troubles of accommodation are presbyopia, spasm, paresis, and paralysis of the ciliary muscle. The last two may follow influenza, typhoid fever, lactation, anemia, diphtheria, or other exhausting disease. The extrinsic muscle-anomalies are usually a loss of convergence. The eyes in all cases of headaches should be carefully examined under mydriasis in persons under 40 years, especially with a view of discovering astigmatism, and the error corrected. [In most cases the limit should be extended up to nearly 50 years of age.]

Of 270 neurasthenic women who had consulted Jones[1] for affections of their pelvic organs, 53 complained of head-symptoms. A large proportion of these suffered from varying degrees of hyperopic astigmatism; 27 were completely cured or greatly relieved by correction of their refractive error.

Gradle[2] maintains that other circumstances besides the optic condition must be taken into consideration in order to account for the variability of the subjective complaints. He refers to "normal asthenopia," where there is an appreciable ratio between the refractive error and the ocular disorder; and to "exaggerated asthenopia," where the relation between cause and effect is out of all proportion. The latter class will generally require the cooperation of the neurologist or general physician.

In young patients suffering from "eye-strain,"[3] who read little, are disinclined to study, are incapable of continued near-work, who wander from one oculist to another, and who have no palpable excuse for asthenopia, the cause will not infrequently be found in **irritation of the genital organs,** and particularly in these days of bicycle-riding, when from a badly-fitting saddle or too continuous riding vulvovaginal or prostatic irritation may be induced and unsuspected.

Coover[4] details 15 cases of **reflex irritation following eye-strain.** Among the prominent symptoms, all relieved by full correction, are attacks of convulsions resembling epilepsy, caused by continued use of the eyes at the near-point. Headache, vertigo, nausea, constant pain over the brows and occiput, restlessness, melancholia, loss of appetite, faintness, insomnia, palpitation of the heart, chorea, stammering, cough without expectoration, irritability, thickness of speech and numbness of the hand and tongue, mental confusion, backache, dyspepsia, are numbered among the symptoms. Halberstadt[5] adds to this list chronic constipation, dysmenorrhea, paresis of cervicospinal muscles, and temporary insanity. Elmer[6] recites examples of patients afflicted with epileptoid seizures, of mental condition approaching insanity, of chorea, and of petit mal, who were entirely relieved by correcting glasses. Lydson[7] also mentions epilepsy as a possible ocular reflex.

Kirkendall[8] cites a case of stammering in a child that disappeared after wearing 4 D. sphericals. He relates 2 cases of elderly persons in whom

[8] Am. Med.-Surg. Bull., Nov. 15, 1895.

nervous dyspepsia was entirely dissipated by the constant wearing of weak plus cylinders for astigmatism against the rule.

Methods of Diagnosis.—Bull [1] divides the visual range into 3 zones, the remote, the mean, and the near. Their extent depends upon the degree of ametropia. He says: "Make all astigmia myopic, and then measure the myopia in the remote zone. It dispenses with the necessity of resorting to the use of mydriatics for the purpose of subjective optometry." [We emphatically dissent. No method at present known can ignore the importance of mydriasis in either subjective or objective optometry.]

Retinoscopy is recognized as a useful adjunct to the list of objective tests of ametropia. Difference of opinion exists as to the source of the boundaries of the shadow. Thus, Weiland [2] demonstrates that the pupil of the observer's eye defines the outline. According to Jackson,[3] the factors that determine the form of the light-area and shadow in the pupil are the refraction, form, and size of the source of light, the form of the patient's pupil and of the sight-hole of the mirror. Bardelli [4] states that all phenomena of retinoscopy have their origin in the effects of light and shade as determined on the fundus by the pupil of the eye examined, while the pupil of the observer's eye does not enter as a factor. Bull [5] claims that the accurate and speedy way to determine proper correction in compound astigmatism is to ascertain and correct astigmatism *first*, and then the spherical defect.

The theory that **corneal astigmatism** is sometimes **corrected by** partial contraction of **the ciliary muscle** is combated by Hess,[6] who claims that previous workers have failed to take into account the play of the pupil and the influence of lid-pressure. In 23 persons, representing all the different refraction-conditions, he was not able to demonstrate in any instance partial contraction of the ciliary muscle. As **factors influencing the corneal curvature,** Lautenbach [7] considers not only the extraocular muscles and the lids, but also the orbital resistance, the ocular pressure, the tonicity of the cornea, and even the ciliary muscle, to be operative.

In a study of 2500 eyes the effort is made by Risley and Thorington [8] to show to what extent **abnormalities in the orbits** were associated with anomalous conditions in the bones of the face and nasal fossa. A number of patients presented a wide difference of refraction in the two eyes, with high astigmatism in one and much lower in the other, and with asymmetrical meridians; and this condition was associated with a well-marked difference in the two sides of the face. These differences suggest not only the probable etiology of the astigmatic eye and its asymmetries, but of many cases of absolute abnormality in the ocular balance, and define the limits of possible relief from treatment by surgical or other procedure.

In an analysis of 1485 astigmatic eyes Kilburn[1] found a larger proportion had **axes against the rule** than other observers had noted, and especially in myopic astigmatism. [This result was due to the method of classification adopted. When the variation was less than 45° from the vertical he classed the case as according to the rule, and when less than 45° from the horizontal as against the rule.]

Davison-Schwarzchild[2] and Mittendorf[3] assert that astigmatism against the rule frequently develops about the presbyopic age in persons who have hitherto not had astigmatism or astigmatism according to the rule, because of alteration of the curve of the cornea produced by change of external muscular pressure which accompanies the phenomena of presbyopia. [It is by no means certain that the extrinsic muscles are concerned in the production of astigmatism in healthy eyes. Moreover, we have not noted that astigmatism against the rule is more common after 45 years than earlier in life.]

Green[4] has shown that when a **spherical lens is tilted forward** through an angle of 15° the maximum increase in the power of the lens is less than one-fourth of the maximum increase of power when the plane of the lens is vertical or when it is tilted forward through an angle of 30°. This principle is applicable to the correction of astigmatism the main meridians of which are vertical and horizontal by inclining spherical lenses without cylinders.

Starkey[5] reemphasizes the frequency and importance of **latent astigmatism.** According to his experience, all latent astigmatism may, in many cases, be made manifest without a mydriatic by giving lenses that correct the manifest error to be worn a day or two, when an additional amount of astigmatism will be manifest that may be corrected, and so on until all the latent trouble is unmasked. This is done without discomfort to the patient—a matter of no small advantage with the skeptical, the nervous, and the irritable. [This method is not without its good features, but it is not admissible in disturbance of the ocular muscles, in which case only the most careful correction under thorough cycloplegia can be accepted as the proper method.]

Prentice[6] in a paper entitled **"The Iris as Diaphragm and Photostat"** offers a theory for the beneficent action of low-power lenses (quarter diopters). Starting with the eyes as a compound lenticular system, he shows how, by preventing spherical aberration, the iris improves the definition of objects. This action on the part of the iris is in excess of that iridic act associated with accommodation. He believes that "a disturbed equilibrium of these functions is probably the cause of asthenopia in low degrees of ametropia." This would also account for the variation in symptoms in those presenting low degrees of ametropia, and would explain why some (those with small pupils) suffer comparatively little, while others (those with large pupils) are practically incapacitated for near-work. Asthenopia is therefore quite as likely to be experienced on account of the size of the pupil as it is on account of

[6] Ann. Ophth. and Otol., Oct., 1895.

refraction. The larger the pupil, the more pronounced will be the improvement in visual acuteness obtained by low-degree corrections. The quarter-diopter lens rarely proves of benefit when the pupils are small. Morrison's[1] studies lend color to the view that the pupillary conditions are well worth weighing in every case of refraction.

Mittendorf[2] affirms, unhesitatingly, his belief in **the value of the quarter-diopter cylinder,** and claims that in a certain proportion of cases even the eighth-diopter cylinder is appreciably beneficial.

The correction of high degrees of optical defect will, according to Dunn,[3] develop symptoms of muscular asthenopia that, with hitherto insufficient or absent corrections, have been latent. By clearly defining the images in each retina the struggle for binocular fixation is infinitely increased, and patients find it impossible to wear glasses that are properly fitted to the ametropia of each eye on account of muscular imbalance. [A point well made. We have seen frequent instances of such developed muscular asthenopia.]

Congenital predisposition to myopia is defined by Schnabel and Herrnheiser[4] as a defective development in either one or both of the ocular tunics in the immediate neighborhood of the optic nerve. They distinguish the sickle-shaped and the annular conus, the former occurring at the side, the latter within the sheath of the optic nerve. Hence all myopias are of the same anatomic origin, and there is but one form of typical myopia. They pronounce as false the view that the myopia of school-life originates in staphyloma posticum, and is likely to progress into malignant myopia, claiming that the development of posterior staphyloma cannot be arrested.

Greef[5] subdivides **high myopia** into the axial and the nonaxial. In the latter class, found most frequently in unilateral high myopia, posterior staphyloma is seldom found. He estimates the refractive value of the myopic lens at from 14–17 D., and contrasts this fact with the unvarying 10 D. equivalence of the emmetropic lens. Of the 3 ways in which the lens may produce myopia—namely, by forward displacement, by increase of its refractive coefficient, and by increase of its anterior and posterior curvature—he selects the last as the most probable factor.

Bitzos[6] concludes that in **the pathogeny of myopia** two factors are essential—elasticity of the sclerotic and an augmentation of the intraocular tension, existing simultaneously. Thus, Puech[7] describes a case of acute glaucoma in a young man who before had enjoyed good vision. After several attacks the eye became myopic, equal to 10 D., from overstretching of the sclera. All occupations or methods of life that contribute to diminish the resistance of the sclera, and those that necessitate increased exercise of accommodation, contribute to the development of myopia. Antonelli[8] demonstrated

[8] Ibid., Sept., 1895.

the increase of refraction in the nucleus of the lens and the acquisition and growth of myopia in a case of iridochoroiditis by means of retinoscopy. [There may also be, in incipient cataract, an increase of refraction of the entire lens.] Roure[1] contends that the myopia so generally found with congenital opacities of the cornea and of the lens is due primarily to dilated pupil, necessary to even moderate acuity of vision, and secondarily to the higher and irregular refraction of the periphery of the lens and the accommodative effort necessary to focus the rays.

Field[2] considers that bright light in the school-room contributes to the increase of myopia among scholars.

Operation in Myopia.—Von Hippel[3] has operated on about 60 cases of high myopia in both young and elderly persons. The indications for the treatment do not rest upon the number of diopters of myopia, but upon the choroidal and retinal changes. One eye was lost by croupous conjunctivitis. Detachment of the retina was never observed after operation. Vision was increased from 4 to 10 fold. Sattler[4] has operated in 85 cases. Vision was increased from 3 to 4 fold only. Both operators declare that there is no nucleus in the lens of the myopic eye. Detachment of the retina followed in 4 of Sattler's cases. [This is no contraindication to operation, since detachment often occurs in nonoperated myopic eyes.] Fuchs[5] speaks of a case in which the myopia increased in spite of the extraction of the lens. Valude[6] is strongly in favor of the operation. Eperon[7] calls attention to 2 errors in the statements commonly found as to the effect of the removal of the lens in high myopia: 1. to consider that because in emmetropia a loss of refraction equal to 10 D. is found; 2. when it has caused a much greater loss of refraction to explain it on the assumption of the greater refraction of the myopic lens. The optical defect varies with each degree of primitive hyperopia or myopia, modified by the effect of the cut on the curvature of the cornea. The opinion that the lens plays an important role in the production of strong myopia, and that it possesses a refractive power superior to that of the emmetropic lens, is erroneous. The corneal curve should be measured in each case to determine its refractive power. [These calculations are based on the assumption that each 3 D. of myopia equals 1 mm. of axial length. While this is true of the lower grades, it becomes more and more incorrect the greater the length of the axis.] Stadfelt[8] believes, with Tscherning, that 16 D. represents both theoretically and practically the optical worth of the lens, for it must be remembered that in spectacles the correcting lens is 15 to 20 mm. in front of the position of the human lens.

Accommodation.—Greef,[9] Axenfeld,[10] Ovio,[11] and Zimmerman[12] are

[12] Arch. of Ophth., Jan., 1896.

agreed that as long as the path for the accommodative impulse is intact the impulse and act are the same in both eyes, whether there is or is not any interest in binocular vision. Seguin[1] asserts that the amplitude of accommodation is higher in those persons whose occupations demand constant use of the eyes at the near-point; the amplitude is less for each age than Donders' tables show.

Presbyopia.—Katz[2] compares thus the tables for presbyopia glasses:

Age.	Donders.	Landolt.	Katz.
40	0	.25	.75
45	1	1	1.5
50	2	1.5	2
55	3	2	2.5
60	4	2.5	3
65	4.5	2.75	3.25
70	4.5	3.3 (3.5)	3.5

[Pilgrim's[3] picture of asthenopia in presbyopia is not overdrawn. He justly ascribes the condition to the use, by the patient, of lenses of his own selection.] Pilgrim's method is to take careful account of the muscular balance after the presbyopia has been corrected. If abduction and adduction sustain normal relationship to each other, 0.37 D. is ordinarily deducted from the strength of the lens with which the patient declared the clearest vision at 14 in. was obtained. If, however, adduction was found to be below par, fully 0.62 D. is deducted, and 2 drops of a $\frac{2}{5}\%$ solution of pilocarpin is used in the eyes night and morning. If adduction is markedly reduced, prismatic gymnastic exercises after Gould's method are recommended, with the use of pilocarpin for a few weeks before glasses are prescribed at all. When defective abductive power is present, usually only 0.25 D. is deducted from the lens preferred by the patient. "In no case, however, should the full strength of the spherical lens selected by the presbyopic patient ever be prescribed."

Hansell[4] defends the use of **eye-glasses,** contending that from the cosmetic standpoint [which is no small one, considering the vast preponderance of women among ophthalmic patients] they are unquestionably to be preferred to spectacles; and arguing from the scientific standpoint they are not contraindicated, inasmuch as properly-fitted glasses will support with precision cylinders, spherocylinders, and prismatic combinations.

Form of Lenses.—Thorington[5] advocates giving spectacle lenses a form that will approximately conform to the limits of the visual field. The resulting lens is ovoid in shape, the sharper end of the ovoid pointing nasally and slightly above the horizontal. As advantages he claims that it gives to the eye that lens which is consistent with the normal field of vision, and, secondly, the edge of the lens is sufficiently removed to be unnoticeable when the eye looks straight ahead. [There is so great an aversion to the use of glasses by the vast majority of those who apply to the oculist that it is only by the most

painstaking attention to the cosmetic effect that they can be persuaded to assume them at all; and while the perimetric lens is a beautiful and scientific idea, we fear that it will never be generally adopted.]

Cycloplegia and Cycloplegics.—Van Fleet[1] disapproves of the use of **atropia** in the determination of nearly all cases of refraction, on account of its uselessness and its dangers, believing that "modern methods" are sufficient without paralysis of accommodation to estimate the error. [Those who endeavor to do careful work will emphatically disagree with the author. His advice not to use it after 40 years of age, unless it is known that no predisposition to glaucoma exists, is sound.]

Murrell,[2] following Hobbs in the use of **scopolamin hydrobromate** as a cycloplegic, finds it satisfactory in refraction-work in $\frac{1}{10}\%$ strength, instilling 1 drop and in 15 minutes another. One hour after the instillation the ciliary muscle will, he claims, be paralyzed.

Morton[3] saw a case of **pseudoerysipelas following the instillation** of $\frac{1}{120}$ gr. **of atropin sulphate** in each eye.

THE ANOMALIES OF THE OCULAR MUSCLES.

Amblyopia without Squint.—[The theories of pathologic processes, such as rupture of the choroid or retina or other traumatism at birth, offered in explanation of amblyopia without squint in an otherwise normal eye, are inconsistent with recovery of vision in amblyopic eyes by means of exercise and cultivation through enforced use. Amblyopia from nonuse can only arise when *all* light is cut off. The amblyopia from squint is psychic, depending upon suppression of the visual image.] Segual[4] and Johnson[5] assume that amblyopia may be induced by the nonuse of the eye. [In Segual's case too many complications were present to warrant the acceptance of the conclusion. It is well known that operation will restore vision to many eyes that from long-standing cataract have been blind for years.]

Diplopia.—Alling,[6] after examining 56 pairs of normal eyes, assumes to disprove Duane's assumption of the frequency of paralysis of the superior rectus,[7] arguing that the diplopia seen at the periphery can be accounted for on physiologic grounds. Duane,[8] replying to Alling's article, reaffirms his former conclusion that diplopia in the periphery of the field of fixation is often due to paresis of the levators.

Three cases of **paralysis of the superior rectus** are reported by Bernstein,[9] who, in summing up, differs from Duane in supposing that they may arise from a lesion of the twig of the oculomotor supplying the superior rectus.

Sauvineau[10] suggests **a new type of paralysis** of horizontal movement of the eyes. A paralysis of the muscles moving the eyes in the same direc-

tion is not a paralysis of such and such muscles, but of certain functions of these muscles, while others are preserved. Foville, Fereal, and Graux describe two types of paralysis of lateral movement, and locate the lesion in the nucleus of the 6th pair.

Abnormal Associated Movements of the Eyelids.—Sinclair[1] says that in cases of ptosis or other paralysis of the ocular muscles movement in the direction of the paralyzed muscle may be effected by facial muscles, and classifies into groups, with explanatory hypotheses, the several associated movements. Hansell[2] reports a case of loss of conjugate divergence or paralysis of external rotation of the eyes in an ataxic young woman of 17. There was no diplopia or squint either manifest or latent. Conjugate deviation was absent. The disks showed no signs of neuritis or papillitis. [The ocular effect of ablation of part of the cerebellum is paralytic, but whether from direct influence of the cerebellum on the muscles or indirectly through loss of cerebral influence is uncertain.] Collins'[3] patient had sudden bilateral loss of convergence. The pupils acted normally, vision was good, the gait was unsteady, station bad, and knee-jerks exaggerated.

Double traumatism of the parietal region caused **paralysis of the external rectus and internal rectus of the right eye** in a patient of Rauge.[4] Bruner's[5] case of paralysis of the superior recti muscles was unique. There was intermittency of the relative strengths of the paretic muscles, although there was nothing to indicate spasm of the inferior oblique; 2° of esophoria were present. The author believes the paralysis was congenital in origin, and that the condition was due to a central deficiency rather than to malformation or arrested development of the muscles.

Functional Anomalies.—Gradle[6] describes asthenopia with insufficiency of convergence. He states that the converging power can be called insufficient only when the eyes cannot converge up to the normal limit in the absence of either paralysis or strabismic shortening of any of the eye-muscles. The measurement by means of prisms held base outward is not a direct test of the converging power; convergence under these circumstances is not a normal movement, but a muscular performance which can be increased by training. Its determination, therefore, does not give as definite a measure of the strength of convergence as the approximation-test. He expresses abduction and adduction in metric angles, and has found that 10 to 12 meter angles of positive convergence and 1 m. a. of negative convergence are the normal strengths. The relation of positive to negative convergence determines whether there is excessive action on the part of one set of muscles or deficient action on the part of the opposing ones. His cases showed muscle-balance at 20 ft., but at 15 in. there was pronounced exophoria. The most marked cases had from 4 to 5 m. a. of positive convergence, while the negative was normal. The degree of subjective annoyance did not correspond with the other neurotic

symptoms. Moreover, under proper hygiene and moderation in the use of the eyes several patients gained considerably in comfort. Gradle inclines to the view that asthenopia, insufficient convergence, and defective accommodation, when found together, are associated manifestations of hysteria. Park[1] proposes the following general rules for the proper consideration of cases of insufficiency of the ocular muscles: All cases of muscular imbalance should be followed up for fully a year before the results are tabulated for publication. Muscular imbalance of from 5° to 15° occurring with hyperopia or hyperopic astigmatism will generally improve under correction of the refractive error, muscular exercises, outdoor life, tonic treatment, and sometimes the temporary use of prisms. The muscular insufficiencies found in myopia and myopic astigmatism require the use of prisms more constantly, and are not benefited as much by muscle-exercises as those occurring in hyperopia, etc. Tenotomies with advancements are generally more effective in myopic cases. Those insufficiencies occurring in constitutional, paralytic, and reflex cases require plenty of rest, outdoor exercising, the temporary use of prisms, electricity, and general tonic treatment. Hotz and Lydston[2] adduce strong evidence in favor of the causal relation of muscular imbalance to reflex headaches and other nervous disturbances. In asthenopia, persisting after the removal of all ascertainable causes, Starkey[3] recommends electricity. For weak extrinsic muscles the primary faradic current is used for its direct effect on those muscles. Asthenopes with almost normal extrinsic muscles should receive the galvanic or secondary faradic current. Oppenheimer[4] indorses the use of strychnin in insufficiency of the interni.

Amblyopia.—Connor[5] adheres to the belief that amblyopia in squint is not the cause, but the result, of axial deviation. All hypermetropes do not squint, because the normal relation between adduction and abduction (4 to 1) is changed by weakness of the interni to 2 to 1, or even 1 to 1. Further, some cases of decided amblyopia will secure full vision after tenotomy and the wearing of full ametropic corrections. [Connor's experience is singularly fortunate. We have never seen marked amblyopia ($\frac{20}{200}$ vision) permanently changed by operation.] Stevens[6] reports a case of hypermetropic **internal squint cured by tenotomy of the superior rectus.** He claims in this, as in numerous preceding articles, that lateral deviation depends upon abnormal vertical tension. [Stevens has offered no explanation for the obliquity of the cornea of hypermetropic squint. It is granted that simple internal squint, depending on hypermetropia, cannot exist. In monocular squint section of the superior rectus is necessary for binocular fixation, but for alternating squint division of each superior rectus, as practised by Stevens, is useless.] Boyer[7] urges painstaking investigation of the ocular conditions in all cases of **vertigo.** In many cases classified with incurable aural affections or tumors of the brain

the vertigo will be found to be the result of imbalance of the eye-muscles, and it will frequently disappear when the equilibrium is restored. The author recites 10 cases in which this treatment was of the greatest benefit, in some instances immediate. He says that, while treatment of aural vertigo is habitually unavailing, the prognosis of ocular vertigo is particularly favorable.

The Operative Treatment of Heterophoria and Heterotropia.—By the use of an instrument which he calls the tropometer, designed to measure the power of rotation of an eye, Stevens[1] determines which muscle is at fault in heterotropia: "I would say that a case of strabismus convergens or divergens is to be studied from the standpoint of the tensions of all the eye-muscles, and that a very large proportion of these, and especially those of high degree, are the manifestations, principally, of vertical tensions." Theobald[2] thinks it may be safely affirmed that, other things being equal, the smaller an eyeball is, and perhaps the more deeply it is situated in the orbit, the less will be the effect of division of one of its muscles; the larger the ball and the more prominent its position, the greater will be the effect.

In cases of insufficiency of convergence Landolt[3] practises advancement of the internus, and, when this is insufficient, tenotomy of the externus. Before resorting to surgical measures he determines the value of rest, prism-exercise, and general tonic treatment; by means of the dynamometer the strength of the muscles, and by the perimeter the degree of excursion. In divergent paralysis advancement of the internus and extensive tenotomy of the externus have given good results. Advancement of a muscle or resection of a tendon as a substitute for, or practised in combination with, tenotomy (a method suggested by Landolt and practised by him for many years), is gaining adherents, among whom may be mentioned Thomas, Savage, and Hansell.[4] The last writer calls attention to the limitations of the usefulness of tenotomy.

Wood[5] and Campbell[6] approve of Savage's and Gould's methods of **prism-exercise** before resorting to tenotomy, both as a means of diagnosing which is the weaker muscle and as a means of treatment. Gould[7] has suggested an addition to our muscular nomenclature—namely, the "upper diplopsic point," corresponding to that degree of combined prism-strengths that first gives rise to diplopia; the "lower diplopsic point," corresponding to that degree of combined prism-strengths, when proceeding downward with the test, at which single vision is resumed; and the "diplopsic zone," or the range between the upper and lower point. Bergeois[8] is a partisan of **advancement.** Savage[9] prefers muscle-shortening in all cases of heterophoria when operation is proposed, regardless of the extent or direction of the turning. In doing advancement Thomas[10] tacks the advanced tendon down to the

[10] Ibid.

sclera. He remarks that "not more than 8° or 10° can be obtained by a partial section," and that "complete section of the muscle may result in 20° to 25° of effect." [The above estimate of the results of complete tenotomy is liberal indeed: the most experienced operators usually secure about 10°, while there are those who do not expect more than 5°.]

Panas[1] regards **incoordination of the centers,** without diminution of the strength of the muscles, as one of the factors in functional internal squint. The local cause is ametropia. Both internal muscles should be divided without delay if other means have not cured the squint by the eighth or ninth year. Hansell[2] sees in hyperopia the origin of the upward squint found so constantly in connection with the esotropia. He thinks it is due to the participation of the superior rectus and inferior oblique in the over-stimulus given to all the muscles supplied by the third nerve in their correlation to the overacting ciliary muscle. Therefore hypertropia in concomitant squint needs no surgical treatment: in constant squint tenotomy of the superior rectus is often necessary. In his estimation, hyperphoria seldom demands operation, notwithstanding the extraordinary claims made by enthusiasts. Partial or complete tenotomy is to be performed only when full correction fails. He looks upon exophoria as a passive condition that cannot be directly ascribed to an error of refraction. Advancement of the interni will often permanently cure.

Bull[3] in a statistical paper publishes data concerning 612 cases of **convergent squint** that had been followed for a time sufficiently long to permit a verdict as to the efficacy of tenotomy and advancement; 597 were hyperopes, 15 were emmetropes, and 18 myopes. In more than one-half of the cases the hyperopia was between 1 and 2 D. The results of tenotomy of the internal rectus of one eye performed in 164 cases were convergence in 62%, parallelism in 33%, divergence in 5%. Both interni were cut at the same sitting in 20 cases: result, convergence in 56%, parallelism in 5%, divergence in 30%. Tenotomy of both interni at different times was done in 186 cases: result, convergence in 79%, parallelism in 17%, divergence in 5%. Tenotomy of the internal rectus and advancement of the external rectus of the same (squinting) eye was done in 222 cases: result, convergence in 16%, parallelism in 80%, divergence in 2%. Tenotomy of the internal rectus of both eyes and advancement of the external rectus of the squinting eye was done in 14 cases: result, convergence in 21%, parallelism in 60%, divergence in 14%. Tenotomy of the internal recti, *and subsequent tenotomy of the internal rectus of the squinting eye,* was done in 6 cases: result, convergence in 50%, parallelism in 16%, divergence in 33%. Summing up the results, we find convergence remaining after operation in 50%, parallelism in 45%, and divergence in 5% of the cases. The improved vision after operation was not due to the operation, but to the beneficial effect of wearing full correction of the optical defect. [This statistical paper establishes what several workers

[1] Arch. d'Ophtal., Jan., 1896. [2] Jour. Am. Med. Assoc., Nov. 2, 1895.
[3] Trans. Am. Ophth. Soc., 1895.

have claimed for some time—namely, that combined tenotomy and advancement is the best method of correcting anatomic squint.]

Ophthalmoplegia.—Marina[1] makes a classic contribution to our knowledge of ocular palsies. His monograph embraces the following classes: congenital cases, bulbar paralysis, ophthalmoplegia externa, polyencephalomyelitis, sclerosis disseminata, syringomyelia, poisons and infectious diseases, polymyositis, polyneuritis, hysteria, cerebral hemorrhages, and other diseases.[2] Jack[3] had a child of 2 years under his care with suddenly-occurring paralysis of all the extrinsic muscles, probably of nuclear origin. There was no history of tuberculosis or syphilis on the side of either parent, and no other disease beyond a few enlarged glands. A history, similar in all respects, of a 1-year-old child is presented by Mary Putnam Jacobi.[4] Hubbell[5] studied nuclear ophthalmoplegia in a man aged 40, who noticed his trouble 28 years before. At the time of report the only extraocular movement remaining was a fair converging power. The iris was partially affected, while the ciliary muscle was entirely immune. The absence of trauma, specific infection, or other disease or diathesis rendered the origin of the affection obscure. Hubbell looks upon it as a "nuclear degeneration" in the fourth ventricle proceeding from before backward. The case of Ayres,[6] of ophthalmoplegia externa, with preservation of the intraocular functions, occurred in a strong healthy man 38 years old, whose history was entirely negative. Webster's[7] case was one of traumatic total ophthalmoplegia with consecutive optic atrophy. The lenticular ganglion was probably injured by a fracture at the base of the orbit.

Recurrent Ocular Palsies.—An instance of recurrent oculomotor paralysis that finally became permanent is recorded by DeSchweinitz.[8] Ormerod and Spicer[9] narrate 7 cases of recurrent paralysis of the different ocular nerves.

Syphilitic Paralyses.—Complete ophthalmoplegia, anesthesia of the cornea, atrophy of the optic nerve, and word-deafness on the left side, followed by similar but less pronounced symptoms on the right side, with death as the final issue, are reported by Dufour[10] as consecutive to gumma of the dura mater in the anterior part of the left middle fossa. There was a smaller gumma in the left olfactory convolution and a third one in the right optic commissure. Duclos[11] ascribes to syphilis a paralysis of the right oculomotor and left facial nerves, appearing within 2 months after the primary sore.

DISEASES OF THE LIDS.

Blepharospasm.—The cause of tonic blepharospasm is local or general.

[1] Ueber multiple Augenmuskel-Lähmungen, Wien, 1896.

[2] His treatment of the pupillary reaction and its relation to diseases of the brain will be found in the section on the Iris.

Pershing's case[1] was attributed to prolonged tension of the nervous system. Of Chauvel's 7 cases,[2] 2 were congenital, 2 appeared in early infancy after convulsions, and in the others blepharospasm followed keratitis and traumatism. Treatment was of no avail in 5, and 2 were cured by section of the infraorbital nerve. Morton[3] was able to greatly improve a case of intractable reflex blepharospasm by stretching the orbicularis muscle.

Mubille[4] thinks blepharitis in children may be caused by the ringworm parasite, since it is often accompanied by patches of ringworm in the other parts of the body. He recommends touching the lid-margins with 2% sublimate, then alternate applications of iodin tincture and the following ointment: Sulphur, 10 gr.; salicylic acid, 6 gr.; vaseline, 5 dr. Dabney[5] cleans carefully the lid-margin, touches it with pure peroxid of hydrogen, and then with the ointment of the yellow oxid of mercury or a weak ointment of the oil of cade.

Chancre.—Simeon Snell[6] observed 9 cases of chancre of the conjunctiva

FIG. 147.—Keber's case of gummata of both upper eyelids (Am. Jour. of Ophth., May, 1896).

of the lids, 3 of which were in children, aged respectively 2, 4, and 11 years. Griffith[7] has seen each year 2 or 3 cases. Darlos[8] had a remarkable case in a

[7] Ibid.
[8] Ibid.

girl of 10 years, whose mother communicated the syphilitic poison in an attempt to remove a foreign body from the conjunctiva. The entire free border of the lower lid was ulcerated and the eyelashes had fallen out. The preauricular ganglion was not involved [contrary to the statement given by Snell that this ganglion is always indurated], but there was an indolent large swelling of the submaxillary and cervical glands. The tonsils were ulcerated. Velhagen [1] also refers to a case of primary sore on the upper eyelid, Keber [2] puts on record an instance of gummata of the eyelids occurring in a man 40 years old (see Fig. 147).

Vaccine Pustule.—Vaccine matter was inoculated into an eyelid of a child by a scratch from another child that had been vaccinated, and whose fingers had been infected by scratching the sore. The cutaneous surface of both lids was converted into a confluent pustule.

Entropion.—Knapp,[3] DeSchweinitz,[4] and Silex [5] resort to transplantation of skin without a pedicle into the intermarginal space of the lid in severe cases of entropion and trichiasis.

Story's operation for entropion and trichiasis [6] was performed nearly 400 times in St. Mark's Ophthalmic Hospital with almost uniformly perfect results. The simple insertion of a piece of mucous membrane completely and permanently removes the cilia from contact with the cornea, does not shorten the eyelid, leaves the Meibomian glands intact, produces no cicatrix to rub the cornea, and leaves an eyelid less deformed than is left by any other method. Péchin [7] considers that in operations for the cure of cicatricial entropion the principal feature in bringing about a successful outcome is a V-shaped incision in the cartilage.

Tumors.—Transplantation of large pieces of skin with a pedicle after 2 operations for removal for the cure of epithelioma was successful in a case of H. Harlan.[8] Three years later the tumor had not returned. Oliver [9] records a good result 16 months after a similar operation.

Dermoid Cysts.—Chauval [10] describes 3 cases of cysts of the conjunctiva and lids. Achenbach [11] agrees with Hebra and Kaposi that horny growths of the lid take their origin from the rete mucosum. Davis [12] recites a case-history that is strongly suggestive of molluscum contagiosum of the lower lid in an infant.

Furuncles.—In the treatment of furuncles of the eyelid Lanvole and Gygax [13] recommend systematic bathing of the lid with salicylic acid 5, borax 3, distilled water 300 parts; or with precipitated sulphur 3, ammonium chlorid 1, rose-water 50, spirit of camphor 20 parts; or with spirit of camphor

and precipitated sulphur, each 5, lime-water and rose-water, each 50, gum arabic 1 part.

Ptosis.—Bernhardt[1] cites a case of synchronous movements of a ptosic lid with certain movements of the inferior maxilla in a 9-year-old boy. The lid-movements were observed only when the mouth was opened widely during the act of chewing and with lateral movements of the lower jaw. Strangely enough, the lid was raised only when the jaw was moved from left to right, and was uninfluenced by opposite movements of the jaw. Tansley[2] operated successfully for congenital ptosis by a combination of the Panas and von

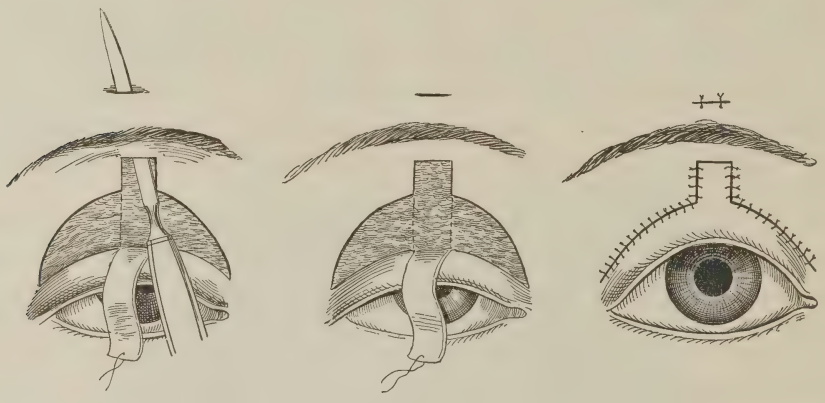

FIG. 148.—Operation for congenital ptosis (Trans. Am. Ophth. Soc., 1895).

Graefe methods (see Fig. 148). Evans[3] operates similarly, but uses silver wire as sutures.

Ectropion.—Hotz[4] approves of **Thiersch grafts** in ectropion and entropion. Augstein[5] considers **excision of the conjunctiva** a necessary part of every ectropion operation. Berger[6] relieved a severe ectropion of both lids, the result of an extensive burn of the face, by transplanting a large flap from the arm. The connection of the flap to the arm was divided on the twelfth day.

Infiltration-anesthesia.—Würdeman[7] in lid operations daily makes use of Schleich's infiltration-method, believing it to be of advantage for most operations in which the use of cocain is inadvisable.

DISEASES OF THE LACRIMAL APPARATUS.

The Tears.—Triboudeau[8] describes the secretion of tears to the influence of a branch of the seventh pair.

Bacteriology of Lacrimal Diseases.—Mazet[9] found in the pus of dacryocystitis the streptococcus, the bacterium coli commune, and the staphy-

lococcus. In 10 cases of mucous dacryocystitis the pneumococcus of Friedländer was very abundant, and the cocci were found to be of great virulence. Fage[1] found a bacillus resembling that of Löffler, except that it is not virulent. Inoculation of cultures will produce purulent inflammation, but without false membranes. It is found in healthy conjunctiva, and requires underlying predisposition to disease to attain pathologic properties. Panas[2] reports a case of double purulent dacryoadenitis accompanying a severe attack of tonsillitis and mucopurulent nasal catarrh.

Puech[3] has seen 2 cases of **lacrimation caused by** the presence in the mouth of decayed **stumps of teeth,** through induction of the chronic inflammation of the antrum and the nasal fossa, thence extending upward into the nasal duct. Galezowski[4] saw persistent lacrimation caused by slowly-growing exostosis of the nasal canal.

Therapy of Lacrimal Diseases.—Duclos[5] recommends **fluorol,** in a strength of half part solution, in the treatment of dacryocystitis, as preferable to sublimate, to nitrate of silver, to the permanganate, etc., because the injections are not painful and are effective.

Thomalla[6] extols **rhinalgin** highly in acute and chronic dacryocystitis. Rhinalgin is prepared according to the following formula: Alumol, gr. $\frac{1}{6}$; ol. valerian, gtt. $\frac{3}{8}$; menthol, gr. $\frac{3}{8}$; cocoa butter, gr. 15. Make suppository No. 1. Use one morning and night in each nasal fossa. Bono and Marchetti[7] recommend the following injection into the lacrimal sac: Pure iodin, 50 c.g.; potassium iodid, 5 gr.; distilled water, 50 pts. Frohlich[8] prefers 10% solution of zinc chlorid as the application.

In the treatment of **lacrimal obstructions** Ramsay[9] urges the necessity of inspecting the nasal cavities and treating any inflammation or hypertrophy that may be present, and of learning whether the patient is a subject of syphilis, since cases intractable to probing are often cured by specific measures.

Diseases of the Lacrimal Gland.—Antonelli[10] reports a case of acute dacryoadenitis of the inferior lobe of the lacrimal gland.

Tumors of the Lacrimal Gland.—Extirpation of sarcoma of the lacrimal glands, traumatic in origin, was performed by Pfingst.[11] Scheffer[12] contributes a similar case. Piccoli's[13] case was one of carcinoma of the lacrimal sac in a woman 56 years old. After removal it recurred, and involved the adjoining bony structure, and caused death 3 or 4 months later. Lick's case[14] of tumor of the gland was microscopically diagnosed a granulation tumor of tubercular origin.

Dislocation.—An infant fell and ruptured the external orbital soft tis-

sues, dislocating the lacrimal gland. Bistis[1] reduced the hernia and sutured the skin. The function of the organ was not disturbed. Von Graefe claimed that the only cause of expulsion of the gland was hemorrhage in the orbit. Galovine[2] restored by operation 2 dislocated lacrimal glands.

Lacrimal Obstruction.—Story[3] prefers the upper to the lower canaliculus preparatory to slitting the duct, because probes can be passed more easily with less twisting and turning, and because subsequent loss of function in the canaliculus is less injurious when occurring in the upper than in the lower canaliculus. Snell[4] advocates the use of the large probes suggested by Theobald, and Vulpius[5] has found that solid probes, equal in size to a Bowman No. 5, with a short horizontal shoulder, and worn permanently, the most satisfactory treatment.

Two more cases of **actinomycosis of the lacrimal sac** are fully considered by Schroeder.[6] In each instance the diagnosis was confirmed by the microscope.

Evetsky[7] confirms the claim made within the past year or two that some cases of apparent closure of the nasal duct, with all the symptoms of dacryocystitis, are really due to the presence of groups of actinomycosis. Division of the canal by Weber's knife and extraction of the yellowish masses will speedily cure.

DISEASES OF THE ORBIT.

Infection.—In empyema of the frontal sinus invading the orbit Snell[8] feels that it is better to operate early than to permit spontaneous opening of the abscess. A very unusual history of a bird-shot penetrating the frontal sinus, there to set up purulent inflammation which later invaded the orbit and induced suppurative orbital cellulitis, is narrated by Schwarzchild.[9] Surgical measures soon set things right. Fully as interesting was Cheney's case[10] of spontaneous perforation of the sclera, with partial evacuation of pus into the tissues of the orbit and possibly infection of the pancreas. The perforation was discovered only after enucleation. Villiard's[11] collection of cases illustrates the various causes of orbital diseases, such as phlebitis of the orbital veins, phlegmon of the orbit of tubercular origin, angina causing suppuration of the eye and death, angina causing suppurative choroiditis with recovery. Fryer[12] reports a case of aneurysm of some of the arteries in the orbit produced by a broken umbrella-rib, which had entered through the conjunctiva close to the inner canthus. Applying a stethoscope over the left common carotid, a bruit could be distinctly heard, likewise over the left temporal fossa, nearly synchronous with the wrist-pulse. A slight ocular pulse

was observed. Mitvalsky [1] teaches that orbital thrombophlebitis, direct or indirect, consists of a purulent inflammation of the veins of the orbit, large and small, arising originally from thrombi whose presence is excited by the diplococcus of Fränkel-Weichselbaum, which exists in innumerable quantity, and of the staphylococcus pyogenes aureus. **Influenza** has to its credit this year 3 cases of orbital cellulitis; [2] 2 died of the general disease.

Diagnosis of Orbital Tumors.—Swanzy [3] lays stress on the following points in the diagnosis of the various neoplasms of the orbit: Exophthalmos or exorbitism; palpation; derangement of vision; pain; loss of motility; pulsation; and the consistence of the tumor. An additional diagnostic sign, according to Jocqs,[4] to which attention has not thus far been directed, is a souffle produced by the pressure of the ophthalmic artery on the branches of the dilated ophthalmic vein. Morton [5] reports a case of primary sarcoma of the orbit in a male 18 years old. An operation prolonged life for some months. Tetanus with fatal termination followed enucleation for sarcoma by Fernandez.[6] Bull [7] contributes a clinical study of several unique cases illustrating the following conditions: Abscess of the ethmoid cells invading the orbit; adenosarcoma and fibrosarcoma of the lacrimal gland; myxosarcoma of the sphenoid, ethmoid, and orbit; malignant tumor of the anterior cerebral fossæ and orbit; sarcoma of the dura mater and orbit; and cystoid angioma of the orbit. [Careful study of these case-histories will indicate what Swanzy pleads for above—namely, the necessity of painstaking differential diagnosis.]

Enophthalmos.—This subject, which has thus far 26 cases in its literature, is considered by DeSchweinitz,[8] who adds the history of a case. He believes that traumatic enophthalmos may be caused by paralysis of Müller's orbital muscle through some lesion of the sympathetic (Schapringer's theory).

Varieties of Pseudoplasm.—Under this heading Panas [9] treats of those orbital tumors reported as lymphoma, sarcoma, or syphiloma. The varieties are syphilitic, gonorrheal, exanthematous, influenzal, leukemic, uterine, and those following purulent ear-disease. Among remedies which may be useful are mercury, the iodids, arsenic, toxins, and the culture of streptococcus of Fehleisen (erysipelas). Kerchbaumer's case [10] could also be properly included in Panas's group. The patient was the subject of leukemia with lymphomatous deposits in both orbits, producing bilateral exophthalmos with low-grade optic neuritis on one side and choked disk on the other.

Ayres' [11] case of lymphangioma of the orbit occurred in a man 53 years old, who otherwise was perfectly healthy. The tumor filled almost the entire right orbit. Microscopically, it showed all the characteristics of lymphangioma cavernosum. Six months later there was no apparent disposition to recur. Knapp [12] removed a cavernous angioma from the depths of the orbit and pre-

served the ball with useful function. A 3-year-old child, presenting 2 tumors at the right side of the head in the neighborhood of the occipitoparietal suture, also right exophthalmos, was seen by Rohmer.[1] The large tumor was the size of a walnut, fluctuating, and was reducible by pressure. When the right common carotid was compressed, a slight isochronous murmur could be heard, the eye returned entirely into the orbit, the cranial tumor diminished and ceased to pulsate, and the souffle was arrested. Rohmer believes the condition was due to a dilatation of the intracranial veins on the right side. Another case in a child of 7 was under the observation of Valude.[2] Exophthalmos had appeared some years before. Three exploratory operations, necessary on account of the recurrence of the exophthalmos, were unsuccessful. A fine needle connected with the negative pole of a galvanic battery was introduced into the bottom of the cavity and the positive pole applied to the jaw. Two applications of 3 or 4 ma. at an interval of a few days sufficed to entirely cure the exophthalmos.

Pulsating Exophthalmos.—A case of probable angioma cavernosum of the orbit is reported by Churchman.[3] At the time of operation there were great exophthalmos, swollen and closed lids, immobile globe, and internal ophthalmoplegia. Vision was $\frac{20}{50}$. The other eye and orbit were normal. Ligation of left common carotid was performed; 2 months later there was perfect motion of the upper lid and almost perfect motion of the ball itself. Vision with correcting glass was normal. Churchman was unable to find any cause whatever.

Dermoid Cysts of the Orbit.—In the case reported by Millikin[4] the cyst sprang from a spur of bone projecting from the roof of the orbit. A circlet of hairs, some of them an inch long, surrounded the spur. Millikin advises total excision when the cyst is small and the walls thick.

Osseous Tumors.—Coppez[5] in an osseous sarcoma of the orbit found the vessels altered and the muscles infiltrated by great numbers of small cells. Martin[6] cured a marked exophthalmos by removing a nasoorbital osteoma.

Endothelial Tumors.—These tumors arise, according to Van Duyse,[7] from the lining membrane of either the blood-vessels or the lymphatics, and are carcinomatous in their nature. Before operating we must determine that they have no connection with the brain.

Syphilitic Disease.—Mandelstamm[8] describes a bilateral syphilitic affection of the orbit. Rebellious at first to vigorous inunction, it yielded later to mercury subcutaneously, after the right eye had ruptured through the cornea. The functions of the left eye were almost completely restored. The final diagnosis was a localized syphilitic process in the orbit at the superior orbital fissure, the gateway of the principal ophthalmic veins and nerves.

In this way the author accounts for the terrific exophthalamos, conjunctival chemosis, and almost complete immobility of the globes. Blessig's case [1] was that of a man 31 years old, married and the father of healthy children. He admitted infection when 18 years of age. In April, 1894, the first ocular symptoms occurred in the right eye. The orbital nature of the affection soon declared itself, and the condition became so threatening by September that complete evacuation of the orbit was done, and a true gumma demonstrated under the microscope. A month elapsed before the affection appeared in the left orbit, and 6 weeks later the patient died. The gummatous process had passed backward through the right optic foramen and sphenoidal fissure into the middle fossæ of the cranium, involving finally the right temporal lobes of the brain. Blessig comments on the want of response to the most energetic antisyphilitic treatment in the case, and quotes Mracek's observation that gummatous processes within the orbit belong to the most obstinate of all syphilitic affections.

Foreign Bodies.—Two unusual cases of foreign bodies remaining in the orbit for 18 and 12 months respectively, without producing irritation, are reported by Hoene.[2]

DISEASES OF THE CONJUNCTIVA.

Conjunctivitis of the New-born.—In Stockholm, Sweden, the frequency of ophthalmia neonatorum between the years 1884 and 1890, inclusive, decreased from 1.2% to 0.25%. This good result Widmark [3] ascribes to preventive legislation and to the general diffusion among midwives of a knowledge of Credé's method of prophylaxis.

Treatment of Conjunctivitis of the New-born.—Hosch [4] disapproves of Credé's prophylaxis, because it induces conjunctivitis and does not prevent purulation. Abadie [5] agrees with him except in cases of gonorrheal infection.

Kalt [6] has used **the irrigation-method in** the treatment of 200 cases of **purulent ophthalmia.** He prefers the less irritating calcium permanganate to the potassium permanganate, 1 g. to 3 liters of water at 25° C., each eye receiving one-half. He orders 4 irrigations (3 with the permanganate and 1 with warm water) daily for the first 2 days, gradually reducing the frequency. Abadie [7] disapproves strongly of frequent washes of strong bichlorid solutions, on account of deep opacity and weakening of the structure of the cornea as a result of their use, especially if iodoform is added to the treatment. He relies upon boric acid and potassium permanganate.

Bardelli [8] speaks in the highest terms of **formol** as an antiseptic in purulent conjunctivitis and keratitis in the strength of 1 : 1500 as a wash.

Wallick [9] calls attention to the danger in unskilled hands of the early use

of the nitrate of silver in purulent conjunctivitis of the new-born, and advocates the method of treatment by irrigation. Vacher[1] has used Kalt's method with satisfactory results. He recommends silver nitrate 1 : 1000, potassium permanganate 1 : 1000, 1 : 2000, 1 : 3000, 1 : 4000, mercuric cyanid 1 : 5000 and 1 : 10,000, and mercuric chlorid 1 : 3000, 1 : 10,000, 1 : 15,000. Sicherer[2] prefers the oxycyanid to the bichlorid, because it is less irritating and causes less precipitation of albumin. Frothington[3] often uses silver nitrate from 40 to 60 gr. solution, and says 10 gr. only shows no result; and Coleman[4] thinks 12% is the proper strength. Scott[5] recommends the following collyrium in the beginning of an attack: Hydrastis sulphate, boric acid, borax, each, 5 gr.; laudanum, ½ dr.; distilled water, 1 oz.

Reynolds[6] advises against the use of nitrate of silver in gonorrheal conjunctivitis, and urges the instillation of Jaenel's emulsion of copaiba, ℥ij; distilled water, ℥vj.

Catarrhal Conjunctivitis.—The bacteriologic study of acute conjunctivitis is placed on a definite basis by the investigations of Morax and Bach[7] by a classification of the different forms of bacteria and description of Week's bacillus. Microscopic examination of the discharge will establish the diagnosis and elucidate the causes of epidemics, distinguishing this form from that in which gonococci, pneumococci, streptococci, or Klebs bacilli may be found. The authors differ from the opinion of Weeks, that acute conjunctivitis is never complicated with lesions of the cornea, and give 6 cases in which superficial involvement of the cornea was present. In the treatment of acute, chronic, or granular conjunctivitis Anderson[8] applies 10% solution of antipyrin, and orders a 4% solution for use at home.

Diphtheric Conjunctivitis.—A case of diphtheric conjunctivitis in which true diphtheria-bacilli were found occurred during an attack of measles, and was complicated by corneal abscess, purulent cellulitis of the lids and cheek, and extension of the false membrane to the nose and throat, in a patient of Guttman.[9] Early in the disease 20 c.c. of antitoxin were injected, but had no influence whatever in staying the progress of disease or in averting the fatal ending. Coppez and Funk[10] speak from a large experience in the highest terms of the efficacy of serum-therapy in the treatment of diphtheric conjunctivitis. They say: "It is superfluous longer to insist on the important role played by serotherapy in the treatment of ocular diphtheria." Hamilton and Embryos-Jones[11] and Lagrange[12] write in favor of serum-injections.

In a study of **the pneumococcus in ocular pathology,** Guenod[13] states it has been found in conjunctivitis, in deep ulcers of the cornea, in

dacryocystitis, and in panophthalmitis. It is a normal resident of the upper anterior air-passages, and causes ocular trouble not only from external conjunctival infection, but by interior infection of the deeper membranes of the eye and the orbit.

Trachoma.—Malgat [1] admits the contagiousness of trachoma, but in a limited sense. Purulent conjunctivitis will, by contagion, reproduce itself only, while trachoma-poison may induce other forms of conjunctivitis. In the former there is no immunity, while in the latter immunity is practicable. The Celtic and negro races, the inhabitants of mountains, children under 12 years, and the nonscrofulous are immune. Van Millingen's [2] conclusions as to the etiology of trachoma—namely, that it is a contagious and infectious disease, not influenced by altitude, and that all races are equally susceptible—Burnett [3] considers are not justified by the facts.

Everbusch [4] and Crainicean [5] discountenance the mechanical treatment of trachoma. Everbusch lays great stress on canthoplasty. In intractable pannus peritomy has failed in his hands. He uses tincture of iodin, making a ring of iodin-spots around the cornea about 3 mm. from the limbus, taking care the spots do not coalesce nor encroach on the corneal tissue. Iodin in its pure state in 0.5, 2.3, or 5% solution in liquid vaselin is also advised by Nieznamoff.[6] Beard [7] applies mercuric bichlorid 1 : 60 or silver nitrate 60 gr. to the ounce, and irrigation by hot boric-acid solution. Geiger [8] pronounces expression of the granules with the thumb-nails and subsequent scrubbing of the conjunctiva with a piece of cotton soaked in mercuric bichlorid 1 : 2000 as decidedly the best method of treating trachoma mechanically. Jaesche [9] prefers expression to all other forms of treatment, though it is a significant fact that he invariably employs a 2% solution of silver nitrate in the after-treatment. Strouse [10] approves of scraping the follicles with a small nonfenestrated soft spoon or "curettage," and then applies 2% solution of silver nitrate. Hellgren [11] prefers Knapp's roller forceps.

May [12] has seen several instances of a mixed form of trachoma and spring catarrh. The symptoms of the latter were added to the former during the prevalence of hot weather.

Vernal Catarrh; Spring Catarrh.—Gradle [13] contributes a summary of conclusions from the observations of vernal catarrh in 8 patients who presented the palpebral form only. The circumcorneal band of infiltration was absent, except in 1 patient, and in this case it was scantily marked. He calls attention to the liability of confusing the palpebral form of vernal catarrh with trachoma. Treatment was symptomatic and the relief temporary only.

Pseudomembranous Conjunctivitis.—Terson [14] asserts that the be-

[13] Arch. f. Ophth., Oct., 1895.
[14] Ann. d'Oculist., June, 1895.

nignity or malignancy of membranous conjunctivitis does not depend upon the presence or absence of the Löffler bacillus, and bacteriologic examinations are necessary to determine the cause with respect to the advisability of employing the serum, yet Jocqs[1] treated a child with pseudomembranous conjunctivitis, the nature of which was not established by bacteriologic examination. Instillations of a weak solution of silver nitrate seemed to aggravate the corneal lesions; they were then touched with $\frac{1}{10}$ to $\frac{1}{20}$ solution of potassium permanganate, which was followed by better results.

Serious **inflammations after** simple and properly-conducted **tenotomy** of the eye-muscles occur occasionally. Bekess[2] saw in a tenotomized eye the diphtheria common in the preantiseptic days.

Phlyctenular Conjunctivitis.—Bach[3] believes that phlyctenular ophthalmias are directly traceable to pyogenic microorganisms—that in recent cases (2 to 3 days) the microbic invasion can be bacteriologically demonstrated. He states that no direct relation exists between these phlyctenular processes and scrofulous affections of the eyes. Woodward[4] in a clinical study of 200 cases attributed the cause to tubercular or syphilitic taint or predisposition, since he found associated with it rhinitis, pharyngeal adenoids, enlarged cervical glands, facial eczema, and blepharitis.

Nuyts[5] records an instance of **traumatic transplantation of ciliæ** from the border of the lid into the conjunctiva, and of their growth in their new position.

Unusual Forms of Conjunctivitis.—Leber[6] observed 2 cases of a new form of conjunctivitis, which he has termed **"conjunctivitis petrificans."** It is a recurring and spreading inflammation, characterized by the appearance on the conjunctiva, slightly raised from its surface, of whitish patches, in the center of which is found a deposit of lime or chalk.

Steffan[7] calls attention to an intractable conjunctivitis secondary to obstruction of sebaceous follicles in the lid-margin. Treatment directed to the little tumor rapidly cures the conjunctivitis.

The experience of Ahlström[8] would seem to indicate that not all atropin conjunctivitis can be traced to microorganisms in the atropin solution. He believes in an idiosyncrasy toward the local action of atropin on the conjunctiva.

Tumors.—Rombolotti[9] divides **conjunctival cysts** into congenital, including dermoids, traumatic, lymphatic, and those from dilatation of Krause's glands. Rogman[10] and Puech[11] agree as to the construction of serous cysts. Steiner[12] relates an instance of **pigment-adenoma of the conjunctiva tarsi** in a Malay. After expiration the exact diagnosis was made by the

microscope. Ayres's[1] study of 3 cases of **dermoid tumor of the conjunctiva** would indicate that the favorite site of these neoplasms is at the limbus. Bassalino and Hallauer[2] saw a **subconjunctival angioma cavernosum** occurring in a young man 17 years of age. Under the microscope the nature of the tumor was plainly shown.

Rogman[3] removed a tumor of 6 weeks' growth, that proved to be a **carcinoma,** from the limbus in a boy of 12 years.

Sawford[4] describes **ophthalmia nodosa** as a disease caused by the penetration into the ocular tissues of the hair of certain caterpillars.

Ewetzky[5] records a case of bilateral **scleroma of the conjunctiva palpebra** diagnosed with the aid of the microscope.

Pterygium.—Deschamps[6] is of the opinion that in the treatment of pterygium careful and vigorous curetting of the cornea should take the place of the galvanocautery. At a meeting of the Soc. d'Ophtal., Paris,[7] several speakers recommended raclage, or grattage—scraping the denuded cornea with a curet after excision of the head of a pterygium—as the most certain method of preventing opacity, and the same method as effective in clearing the cornea in band-keratitis. Coe[8] is satisfied that the whole trouble in pterygium lies in the apex, and that the vascular supply is not a part of the disease, but only an effect. He secured surprising results in 2 cases by simply touching the apex with the actual cautery. Within 6 days there was scarcely a trace of the former trouble. Steiner[9] by means of the microscope was able to diagnose a cancroid of the cornea that made its appearance at the apex of a pterygium.

Hemorrhage.—Stoewer[10] relates the history of fatal conjunctival hemorrhage in an infant of 6 months. The blood came from a small polyp in the superior culdesac, and ceased only during sleep.

Syphilis.—Snell[11] has observed 9 cases of chancre of the lids and conjunctiva. The preauricular ganglion in all, and in some the submaxillary ganglia, were enlarged. Morton[12] reports a case of secondary ulcer of the conjunctiva in a woman aged 46. The ulcer healed perfectly under specific treatment.

DISEASES OF THE SCLERA.

Episcleritis.—Fuchs[13] describes an infrequent affection of the episclera characterized by congestion of the ocular conjunctiva and intense injection of the episcleral vessels, without, however, the formation of scleral nodules. Fuchs has named the affection "episcleritis periodica fugans." To the above

observation Stephenson [1] adds the report of several cases of this newly-described disease in children.

In addition to the usual treatment of episcleritis, varying with the exciting cause or diathesis, Veasey [2] finds that many cases that resist all other treatment are markedly improved by a few applications of galvanism.

Parasites.—Hirschberg [3] reports finding an ocular parasite, the filaria loa (see the *Year-Book* for 1896, p. 778), imbedded between the sclera and the choroid of a South African negro. He extracted it without difficulty.

THE IRIS AND CILIARY BODY.

Congenital Anomaly.—*Albinism.*—Malgot [4] holds light irides to be a variety of albinism, an arrest of development of the pigment-granules, arising from an imperfect nutrition of the anterior section of the eye. Four cases of **albinism** are reported by Jennings.[5] In all of them there was marked diminution of the visual acuity.

Physiology.—Gifford [6] states that contraction of the pupil is associated with strong contraction of the orbicularis, and particularly the palpebral portion of the latter muscle. He explains this iris-reaction by Mendel's theory that the fibers of the 7th nerve, which supply the orbicularis, arise from the nucleus of the 3d, remarking, however, that it is equally explainable by Bechterew's idea that special fibers connect the nucleus of the 3d with the 7th nerve. This view is strengthened by Silex's [7] investigations of 3 cases of paralysis of the orbicularis, without paralysis of other muscles supplied by the 7th. Marina [8] records his conviction that the frequency of iridoplegia in tabes argues for an extracerebral center, or at least for a second center interpolated between the oculomotor and short ciliary nerves. [This view is in accord with the neuron-theory.] Marina inclines to the belief that the principal center for pupillary contraction is to be found in the ciliary ganglion.

Functional Diseases of the Iris and Ciliary Body.—Moll [9] in reviewing 150 cases of **postdiphtheric cycloplegia** seen in Hirschberg's clinic found the average duration of the paralysis to be about 4 weeks. He also discovered that abducens paralysis occurred in more than 10% of the cases, and feels that, after diphtheria, examination of the eyes of children with a red glass for diplopia would reveal abducens paralysis in a much greater percentage of cases than is now thought to obtain.

Feilchenfeld [10] relates that several army officers partook of some canned oysters and showed general toxic symptoms 5 days afterward. They all complained of inability to read, but only one of them submitted himself to examination, when it was found that there was complete paralysis of accommodation, which lasted for 2 weeks.

Henry[1] has constructed a pupillometer which enables him to show that **the pupil** always **reacts when a portion of the iris is submitted to the action of light,** without modifying the illumination of the retina. A dark-colored iris will dilate more than a light one. The author views this as an explanation of the photophobia of iritis at times when the retina is not involved in the inflammatory process.

Diagnosis of Iritis.—According to Friedenwald,[2] the cornea is affected in every case of iritis. In no case does it retain its perfect transparency. The opacities consist of deposits upon Descemet's membrane and infiltrations in the substantia propria. It is these deposits which cause the pupil and iris to appear blurred and hazy, and which are often referred to as muddiness of the aqueous humor.

Manz[3] affirms that **ocular tuberculosis** is more frequent than is generally supposed. He claims that often the iritis is assumed to be rheumatic or luetic when careful search into the general condition of the patient and the family history would reveal the true nature of the disorder. He looks upon the formation of small grayish-white nodules in the conjunctiva, cornea, or iris as a valuable diagnostic sign.

Iritis of nasal origin is reported by Fage.[4] There was no other cause than atrophic rhinitis.

Acute Plastic Iritis.—The analysis of Bruns'[5] 105 cases indicates that acute plastic iritis, whether specific or not, is a self-limited disease, and that, while local treatment is of the greatest value in soothing the pain and preventing adhesions, constitutional treatment will not tend to shorten the duration of the disease. Tansley[6] reports a case of iritis that continued over 18 months with numerous relapses, in which no cause could be shown. Gaupillat[7] shows that anterior synechiæ predispose an eye to long and repeated attacks of inflammation and perhaps sympathetic disease. Terson[8] accords with this view.

Iridocyclitis.—In the case of a man reported by Oswalt,[9] aged 39, a gumma developed 14 years after syphilitic infection in the upper outer ciliary region, growing into the anterior chamber. The tumor finally decayed under antisyphilitic treatment. Gallenga[10] observed an instance of gumma of the ciliary body that appeared 2 months after infection. Ellett[11] records a case in a man aged 29 of plastic cyclitis, with localized exudation, occurring early in secondary syphilis and resembling gumma of the ciliary body.

Leprosy.—Norsa[12] describes leprous iritis. In the nodules which form in this intense variety of ocular inflammation leprous bacilli may be found.

Grandclement[1] finds that **hernia of the iris,** left to itself, constitutes a permanent menace to the eye. He advises incision by boldly dividing the hernial protrusion into equal parts in the direction of its greatest diameter. [Experience amply justifies this fear.]

Suker[2] pronounces **ephedrin hydrochlorate** the best mydriatic for diagnostic purposes, because of its rapidity of action, the short duration of its effects, its noninterference with accommodation or intraocular tension, its maximum dilatation of the pupil, and its freedom from untoward effects.

Tumors of the Iris.—In a case of carcinoma of the iris and ciliary body reported by Robertson[3] the disease, though primary, sprang from the iris rather than from the ciliary body. Hansell[4] reports 2 cases of tumor of the iris—1 a pearl cyst due to traumatism, the other a fibroma in which no tubercles could be discovered on staining.

Injuries.—Isolated rupture of the iris, perpendicular to its radiating fibers, and unaccompanied by any injury whatsoever of the adjacent tissues, is reported by Reber.[5]

SYMPATHETIC OPHTHALMIA.

Pathogenesis.—Deutschman's migration theory has not been supported by recent investigations, and in view of the reports of carefully conducted examinations by DeSchweinitz,[6] Stricker,[7] Bach,[8] Burgeois,[9] Ring,[10] and Collins,[11] the theory should be abandoned. DeSchweinitz found no bacilli in 3 cases of enucleation for threatening sympathetic ophthalmia following injuries. Further evidence that sympathetic inflammation is not due to the migration of bacilli is furnished by Collins, whose thorough investigation of an eye enucleated during the active stage of inflammation of both eyes failed to reveal the presence of microorganisms. Bach's experiments convince him that a migration of bacteria from the first to the second eye along the optic sheaths does not occur in the sense of the migration-theory. The path of the irritation is from the first eye through the ciliary nerves to the ciliary ganglion, through the sympathetic root of the latter to the carotid plexus of the same side, then through the circle of Willis to the carotid plexus of the other side, and then in a centrifugal direction to the ciliary ganglion and the ciliary nerves of the second eye. In a later communication[12] Bach adheres to his original position. As to therapy, he argues for section of the ciliary nerves. Evisceration is surer than the previous measure, but enucleation offers the greatest security. Zimmerman[13] states that in a close anatomic study of a case of sympathetic ophthalmia he found unmistakable direct transmission of

pathogenic micrococci from the offending to the sympathizing eye. Stricker,[1] too, notwithstanding negative bacteriologic findings in a case of his own, allies himself with the apostles of "migration." He is convinced that "every perforating wound of the eye, be it the result of disease, accident, or operation, opens the door for the entrance of pathogenic microbes, without which there can be no sympathetic ophthalmia."

Prognosis.—Rogman[2] believes that sympathetic ophthalmia is not an incurable disease, although a cure must not be admitted until some years have passed. This conclusion is confirmed by Lagner,[3] who reports 5 cases (2 of which formed the basis of Rogman's article) that in spite of enucleation of the injured eye developed severe sympathetic iridochoroiditis. By treatment and operations vision, that had been nearly lost, was restored. Ledbetter[4] and Simi[5] had similar fortunate experiences. The former lost a left eye after discission of a soft cataract. The right eye, on which he had previously done the same operation with good results, sympathized, and vision was reduced to counting fingers. Enucleation immediately relieved the inflammatory symptoms and saved the remaining eye. Simi treated a case of violent sympathetic inflammation by enucleation of the exciting eye, subconjunctival injections of cyanid of mercury and mydriatics locally, and corrosive sublimate internally, finally securing $\frac{7}{10}$ of normal vision.

Opticociliary neurotomy [an operation that has few advocates] was successfully performed by Burnham in sympathetic disease.[6]

Sponge-grafting.—Belt[7] suggests, after removal of the ball, the insertion of a piece of sponge, over which the conjunctiva is sutured, in the socket. The interstices of the sponge become filled with hard flesh, furnishing a firm support for an artificial eye.

GLAUCOMA.

[The tendency among clinicians to disassociate simple or noninflammatory glaucoma from the category of glaucomas is evident since Schweigger's masterly article, published 3 years ago in the Archives of Ophthalmology.]

A careful analysis of a series of cases has been prepared by Zentmayer and Posey.[8] The systemic diseases predisposing to simple glaucoma are rheumatism and influenza, typhoid and malarial fevers, and other devitalizing conditions. Some of their observations may be briefly stated: The disease is almost without exception binocular, an average period of 20 months elapsing between the involvement of the first and second eye. In 32 of the eyes with full visual acuity there were distinct glaucomatous excavations; in the majority of cases there were no signs of inflammatory process. The pupils were dilated ad maximum in 19—5 of which were sluggish and 14 nonresponsive. The media were clear in only 47 cases. Every nerve the seat of a glaucomatous

excavation was gray, green, or blue in tint. In 65 the excavations involved the entire nerve-head, averaging 3.37 D. in depth. A broad scleral ring all around occurred in 147, and marked halo 31 times. Simi[1] ascribes a case of glaucoma to aortic insufficiency. Simon[2] states that a careful estimation of the visual fields in glaucoma will often show peripheral scotomata, relative or absolute, just skirting along the margin of the already contracted field. They are of considerable prognostic value in his mind, inasmuch as they precede the formation of sectors or defects in whatever portion of the field they may be found.

Lippincott[3] saw a case of simple glaucoma develop into the inflammatory form.

Theories.—The retention-theory—that is, the interruption of the escape of the secretions through the angle of the anterior chamber—is strengthened by experimental investigations of Beutzen and Leber,[4] but they are not prepared to say what factors may cause this interruption. This view is also held by Koster.[5]

As to the part that the endothelial cells of the anterior chamber may play in the etiology of glaucoma, Alt[6] says: "From my specimens it seems to me apparent that the obliteration of the iris-angle is surely not due alone to pressure from behind, but to a new formation of tissue in the iris-angle, which, when contracting, pulls the iris-periphery toward the corneal border, and when it shrinks farther leads to union between the iris and corneoscleral tissue." Radzveitzky[7] had an unfortunate experience. A few hours after iridectomy for simple glaucoma the instillation of 4% cocain solution developed acute glaucoma. In spite of eserin, morphin, and antipyrin, the symptoms continued intense, and disappeared slowly only after sclerotomy. Zirm[8] lays stress on narrowing of the vortex-veins as contributing largely to the clinical picture of glaucoma.

Diagnosis.—Galezowski[9] differentiates glaucomatous excavation in atrophy of the nerve from the simple excavation of atrophy of spinal origin, thus: In glaucoma the papilla is white, particularly externally; the central veins of the optic nerves are diminished in volume at their point of emergence, but at the border of the disk they become larger; there is pulsation of the central artery under digital pressure; the pupil contracts to light, but is dilated and irregular; the visual field is limited above, and, much later, in the remaining portions; dyschromatopsia does not exist at the beginning, but later becomes marked; the knee-reflex is preserved, and there are no shooting pains; the affection is gouty, rheumatic, or syphilitic.

Germann[10] reports a case of empyema of the right antrum of Highmore,

presenting all the symptoms of glaucoma, in which the right eye was iridectomized. Later the antrum-trouble was discovered and relieved, whereupon all the eye-symptoms disappeared.

Treatment.—Testimony as to the great value of the medicinal treatment of glaucoma is furnished by Cohn.[1] By the daily use of a ½% solution of eserin sulphate for 14 years acute attacks had been either prevented or cured, and the acuity of vision and the visual field had been preserved. An omission of the instillation would be followed by glaucoma symptoms. Iridectomy is justified only in those cases in which the employment of myotics cannot check the evolution of the disease, since its results are inferior to the treatment by myotics. Abadie[2] too believes that simple glaucoma is not cured by iridectomy, but is more amenable to systematic and prolonged local instillation of eserin or pilocarpin, and to the administration internally of potassium bromid and quinin. Simi[3] concurs in this treatment. On the other hand, Nettleship[4] urges iridectomy first in cases of optic atrophy occurring during the glaucoma-period of life, in which there is distinct cupping of the disk, even though the tension may not be increased; and secondly, even in those cases in which the field of vision is cut off close to the fixation-point; thirdly, in simple glaucoma, early in the disease; fourthly, sometimes in the prodromal stage, especially in young persons. The order of remedies adopted by Wicherkienicz[5] is first eserin, then sclerotomy, and finally iridectomy. Ramsey[6] advises iridectomy in all forms of glaucoma so soon as the diagnosis is established.

Indovini[7] reports results of operations of division of the external nerve (**operation of Badal**) performed by Angellucci in 13 cases. The operation cannot be considered as a radical treatment of glaucoma, but as an excellent means to control pain in absolute glaucoma. Pain can be relieved, according to Sutphen,[8] by sodium salicylate. Risley[9] has had equally good results from sodium biborate, and thinks it is the sodium that is the valuable agent.

Abadie[10] adds a new case of **sympathetic glaucoma** to the very few that have been reported. The second eye was cured, not by iridectomy or sclerotomy, which he discountenances, but by enucleation of the first eye and by instillation of eserin.

Schweigger[11] says glaucoma not unfrequently shows a **malignant tendency after iridectomy.**

DISEASES OF THE CHOROID.

Hemeralopia.—Krienries[12] looks upon hemeralopia as choroidal, and not retinal, in origin. He thinks it occurs only in the presence of ocular mal-

[1] Berl. klin. Woch., May 27, 1895.

[12] Ueber acute idiopathische Hemeralopia, Wiesbaden, 1896.

nutrition, and that the predisposition may be either congenital or acquired. This ocular malnutrition gives rise, in turn, to a disturbance in the balance between the production and the use of the visual purple. The most efficient treatment thus far found is strychnin, hypodermically, in increasing doses. Carpenter[1] considers colloid changes in the choroid and "drusen" of the optic nerve-head, viewed from the ophthalmoscopic and clinic standpoint, as identical.

Albuminoid deposits in the optic disks and retina are, according to Heyl,[2] derived from the choriocapillary system.

Conus.—Randall[3] urges the careful study in all refractive conditions of the excavation and configuration of the disk, trend of the vessels, and pigment alterations of the choroid, especially conus.

Inflammation.—Rochon-Duvignaud[4] believes that in specific retino-choroiditis the choroid is primarily affected, the retina secondarily, because the retinal lesions are limited to the foveal region, while those in the choroid are more disseminated. Houdart[5] found concentric limitation of the field in a case—[a finding that tends to disprove the assertion that the retinal lesions are limited to the foveal region]. The fields were enlarged by mercuric inunction. Schmeichler[6] records 3 cases of metastatic choroiditis, 1 secondary to purulent cystitis, the second to a splenic abscess, the third directly consequent to puerperal fever. The ages of the patients were 74, 25, and 35, respectively.

Tumors.—Mitvalsky[7] argues that choroidal tumors (sarcoma) may develop only laterally, and involve the whole uveal tract without projecting into the vitreous, and can be recognized during life only very late in their course by the formation of episcleral nodules. Griffith[8] reports 2 cases of choroidal sarcoma in infancy. The author believes that intraocular neoplasms occurring in infancy are sarcomata, whether their seat of origin be in the retina or in the choroid.

Microscopic examination of sarcoma of the choroid, arising from injury, made early in its progress by Buller,[9] shows that the growth is almost wholly confined to the choroid. Eighteen months after enucleation there was no recurrence. [Cases that have survived 15 years after enucleation of the choroidal sarcoma have been reported.]

Guaita[10] describes the third case recorded in literature of myoma of the choroid. Its origin is in the fine muscular tissue of the choroid, and its growth, by proliferation of its superficial elements, rapid.

Detachment.—Marshall[11] has observed 3 cases of detachment of the choroid, 2 subsequent to glaucoma, and one 6 months after the extraction

PLATE 12.

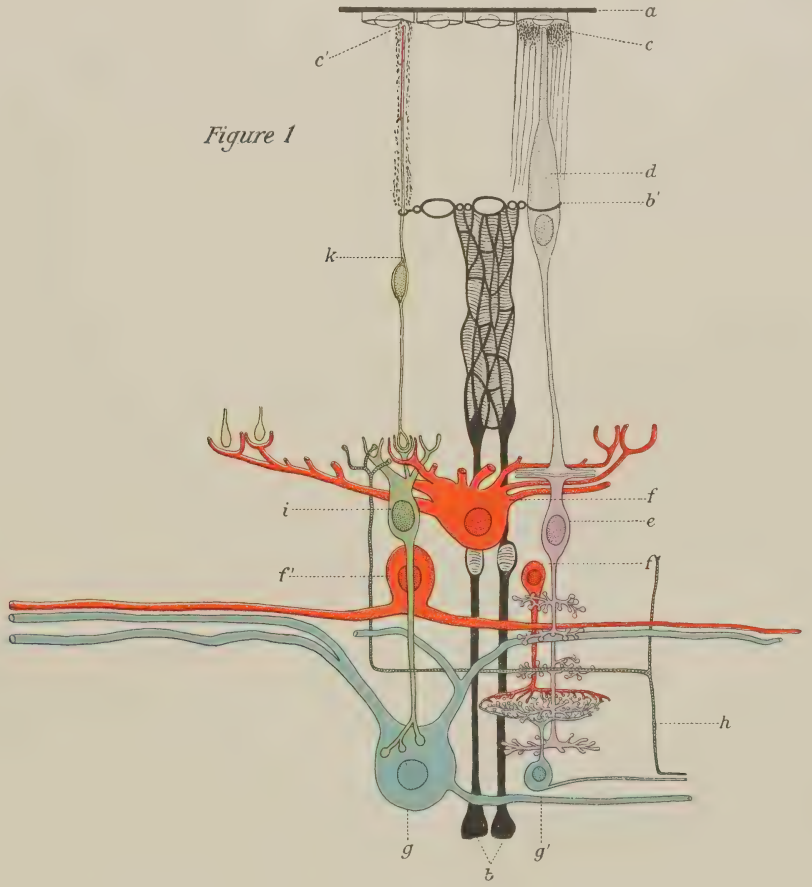

Figure 1

Figure 2.

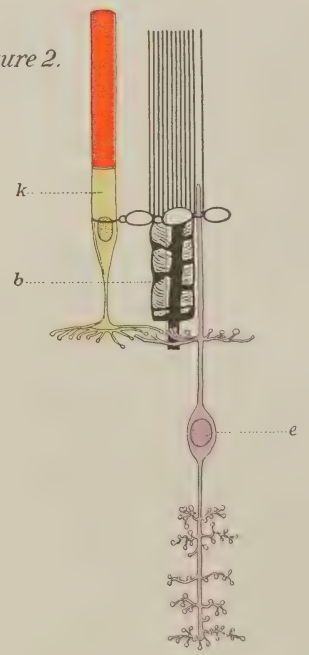

FIG. 1.—Schematic section of the mammalian retina. FIG. 2.—Scheme of the relation of the rod- to the cone-system as existing in the retinæ of amphibians, reptiles, and birds. (Ernst Weinland, Neue untersuchungen über die Funktionen der Netzhaut, Tubingen, 1895.)

of cataract. Under the choroid were found serous and fibrous exudation and the formation of cysts.

Heyl[1] believes that **spontaneous rupture** of the choroid is horizontal when its seat is in the macular region, and that it is caused by spasmodic contraction of the external rectus or a number of such contractions—that the macular changes found in high myopia may arise from excessive action of the external rectus. How far the choroid coat is involved is unknown. The conspicuous feature of the lesion is the splitting of the pigmentary layer of the retina.

DISEASES OF THE RETINA.

Anatomy.—Hosch[2] adheres to the classical division of the retina into three layers. Norris[3] shows by microphotographs that the rods and cones in the human retina are connected by loops—each rod with its adjacent cones—and believes that the seat of light-perception is in the outer segment of the rods and cones, which are the only parts of the retina that are bathed in the visual purple. Weinland[4] states that there is but one visual substance in the retina, which has its seat in the summit of the "goblet" (the so-called pigment-) cells (see Plate 12). The chemic change which light works on the visual substance produces an increase in volume of the goblet-cells, transmitted to the rods as a pressure-stimulus. [The theory of referring our perception of light to what is primarily a pressure (instead of a vibratory) phenomenon is so radical a departure from generally accepted views that it will require the greatest plausibility before it can be adopted even as a working theory.]

Physiology.—Posey[5] regards the different forms of visual perceptions as expressions of impaired function, or merely symptoms of disease of the nervous structure of the eye or of the expansion of the optic nerve within the brain.

Light-sense.—Ahlström[6] finds "the sensibility to luminous impressions is not the same throughout the entire retina, but greatest in the fovea and neighboring parts, and diminishes uniformly toward the periphery. [The information gained in these and similar experiments is entirely subjective, and must depend not only on the sensibility of the retina, but the ability to discriminate between sensations, which varies according to the personal equation.]

Retinal Tire and Hysteria.—Schmidt-Rimpler[7] believes concentric contraction of the visual field, frequently found in hysteria, to be a simulated condition. Sudden loss of vision continuing 8 days and returning as suddenly occurred in a young hysterical woman under the care of Claiborne.[8] Berger[9] calls attention to the hysterical zones of the retina in certain patients. In the case detailed the patient had a very high degree of hyperopia and astigmatism,

suffered attacks of intense pain, and had concentric limitation of each field, particularly on the most painful side. After use of the eyes and after attacks of pain the field of vision was decreased. [The hysterical symptoms in these cases were most likely due to the prolonged use of eyes that were entirely unfitted for near-work, and the limitations of the field were rather functional than hysterical.]

Amblyopia.—Johnson[1] adds a third to his 2 cases of amblyopia exanopsia previously reported.

Retinal Hemorrhage.—Vialet[2] reports a case of double retinal hemorrhage in a young man that he traced to hemophilia, because his grandfather, father, and daughter were subjects of severe hemorrhage from insignificant causes. The urine showed neither albumin nor sugar. Trousseau[3] gives as a cause of repeated retinal hemorrhages in a man of 30 the excretion of large quantities of urea and phosphates in the urine. By treatment the urine was rendered normal and the hemorrhages ceased. Friedenwald[4] cites 2 cases of hemorrhage into the retina and vitreous, both of which presented such marked evidence of vascular disease as to lead to the view that in young persons intra-retinal hemorrhage may be often due to disease of the retinal vessels. In another communication[5] he enters minutely into the details of 2 somewhat similar cases originating in demonstrable lesions of the retinal veins.

Three cases of pernicious anemia, caused by the presence of tenia, exhibiting profuse retinal hemorrhages, are reported by Natanson.[6] Violent exercise will at times produce rupture of a retinal vessel, as is instanced by the case of Foster,[7] in which a blind spot caused by a large macular hemorrhage was noticed by the patient while "scorching." The 4 cases of injury to the eye by a blow from a blunt object investigated by Siegrist would seem to indicate that the resulting choroidal and retinal changes, as seen with the ophthalmoscope, are to be ascribed to a rupture of one of the ciliary arteries in the external tunics of the globe.[8] Two instances of circumscribed macular hemorrhage are reported by DeSchweinitz,[9] one following iridectomy done for glaucoma, the other in a woman of 66 who was the subject of chronic heart-disease.

Albuminuric Retinitis.—Nuel[10] finds the pathology of the macular changes in albuminuric retinitis to consist in hypertrophy of the rods and cones and their inclination toward the fovea, instead of being at right angles to the plane of the retina. In the external granular layer are patches filled or surrounded by exudation. This exudation is, as a rule, homogeneous, albuminous, and fibrous. The interstitial edema separates the normal fibers in their length, making large spaces between them. Study of the exudation demonstrates

positively that these changes have taken place during life. Just under the macula the choroid exudes a lamella of tissue, destroying the rods and cones, and a homogeneous substance that seems to be identical with the retinal exudation and probably produced at the same time. It causes a minute detachment of the retina.

Retinitis Pigmentosa.—Belt[1] recites fully 2 family histories in which 50% of the members were affected with retinitis pigmentosa. In neither family could any history of eye-trouble, syphilis, or inebriety be shown. On the other hand, there was close consanguinity in both families, which is adduced as an argument for consanguinity as a factor in retinitis pigmentosa. These views are negatived by Hansell's[2] case. He met the disease in a deaf-mute, who was of fine physical proportions, excellent health, and whose history, likewise his family history, was absolutely negative. Atwood[3] observed marked night-blindness, probably hereditary, in a young man who had no other ocular symptoms of retinitis pigmentosa. In a case of retinitis pigmentosa with hemeralopia of many years standing Trantas[4] found double annular scotoma between 20° and 40°, according to Parinaud's perimeter, with

FIG. 149.—Upright image, left eye, of one of Hirschberg's cases of congenital specific retinitis. Vision in this eye, with —7.00 D. S. = $\frac{5}{8}$ (Deutsch. med. Woch., 1895, Nos. 26, 27).

otherwise normal fields. [This is a very uncommon condition. There was no error in the examinations, as they were repeatedly verified.]

[1] Med. News, Jan. 18, 1896.

[3] Roy. London Ophth. Hosp. Rep., 1895, pt. 1.
[4] Rec. d'Ophtal., June, 1895.

Annular scotoma has been found in hyperemia of the retina from the glare of electric light, from direct exposure to the sun's rays,[1] in lead-poisoning, in chorioretinitis of specific origin, and in disseminated choroiditis.

Diabetic Retinitis.—Alt[2] adds 3 to the 60 cases of diabetic retinitis reported up to date; 1 of his cases was typical, the other 2 atypical.

Syphilitic Retinitis.—Hirschberg[3] directs attention to the frequent, but often overlooked, occurrence of deep-seated eye-diseases in congenitally syphilitic children. Next to diffuse keratitis in order of frequency he places a peculiar form of retinitis consisting in a pigment-disturbance of the retinal periphery (see Fig. 149). He urges the careful ophthalmoscopic study of all suspected cases in children, no matter how young. Mercurial inunctions have been marvellously efficient in his hands.

Detachment of the Retina.—Bach[4] shows that in animals, after a retina has been detached 2 months, the ganglion-cells undergo degeneration of their finer elements to such a degree as to render fruitless any attempt at restoring their function by reattaching the retina. From this he concludes that after a certain period (longer in man than in animals because of differences in circulation) nothing can be gained by securing the reattachment of the loosened retina. According to Galezowski,[5] retinal detachment is due to a disease of the lymphatic vessels, through which passes nutritive material to the choroid and ciliary body, with consequent alteration of the supply of new material. Teillas[6] reports a case of double detachment of the retina in a child with pertussis. Tweedy[7] has operated on many cases by all the known methods without obtaining permanent recovery. His statement is not supported by Wray,[8] who operated on a patient by puncture 8 years after the retina had become detached, followed by daily injections of pilocarpin and rest in bed. Vision was improved from light-perception to $\frac{1}{4}$. The contra-indications for operation are—1. Detachment in the macular region; 2. Extensive hemorrhage; 3. Very low tension. Little, Walker, and Marshall[9] have had successes, and Lang and Jessup[10] have seen spontaneous recovery.

Milliken's[11] case of macular detachment occurred in a man 80 years old. The eye had previously been perfectly healthy. The detachment was a small one, limited to the macular region. There was complete spontaneous reattachment of the membrane in 3 months, and visual acuity of $\frac{6}{9}$ with a correcting glass. Gourfinkel[12] reports a case of spontaneous cure of a large detachment of the retina in an eye that was damaged by iridochoroiditis. Marchetti[13] advises for detachment puncture of the sclera, rest in bed, pilocarpin and mercury; while Simi[14] has had imperfect success with the electrolytic treatment of detached retina.

Tumors.—Treacher Collins[1] enucleated both eyes for glioma in 4 cases. If it be true that glioma always recurs in 3 years, the 4 cases were cured. Bocchi[2] reports a case of tumor of the retina of a sarcomatous nature.

Choroiditis after measles may eventually show the characteristic symptoms of glioma. The choroiditis may give at first no signs of its presence, but later the vitreous becomes filled with yellow exudations. Cramer and Schultze[3] examined the ball of a girl of 15 which had shown before enucleation signs of glioma, but there had never been a local inflammation, and the only history was that of scarlatina 10 years previously.

DISEASES OF THE VITREOUS BODY.

Hemorrhage.—In the case of a young man, the subject of vitreous hemorrhage in both eyes, who remained amblyopic for several months in spite of internal medication, Abadie[4] penetrated the vitreous of the left eye with a very fine platinum-pointed needle connected with the positive pole of a galvanic battery, the negative pole being applied to the arm. For 5 minutes he passed a current of about 3 or 4 ma. The following day the patient could count fingers. Vision improved until he could read names and numbers on houses. The right eye (not treated) remained without qualitative perception of light and the vitreous opaque. Kipp[5] noted in a boy's right eye hemorrhage into the vitreous. Some years afterward the patient had an attack of a similar nature in the left eye. Vision gradually rose to normal; 6 years later he had a second attack in the left eye, from which he fully recovered.

Berry[6] has used chlorin-water injections into the vitreous to prevent purulent inflammation in the beginning of septic disease and after the removal of foreign bodies.

Subjective Visual Perceptions.—Gould[7] urges that these have not been studied by scientific methods to the extent their importance warrants, and he proposes for them a more definite classification and nomenclature. He classes them as—1. peripheral, 2. central, and 3. combinations of the two, which he calls peripherocentral or centroperipheral according as they are primarily or preponderatingly peripheral or central. He proposes to call all positive light-sensations phoses, and to divide them into peripheraphoses and centraphoses, according to their origin. Absence or interruptions of light-sensations, as scotomata, shadows, whether formless or of more or less indeterminate form, he would call aphoses, and divide according to origin into peripheraphoses and centraphoses. Colored light-sensations would be chromophoses, and could be subdivided, according to the color exhibited, as erythrophoses when red, cyanophoses when blue, xanthophoses, indikophoses, ionophoses, chrysophoses, etc.

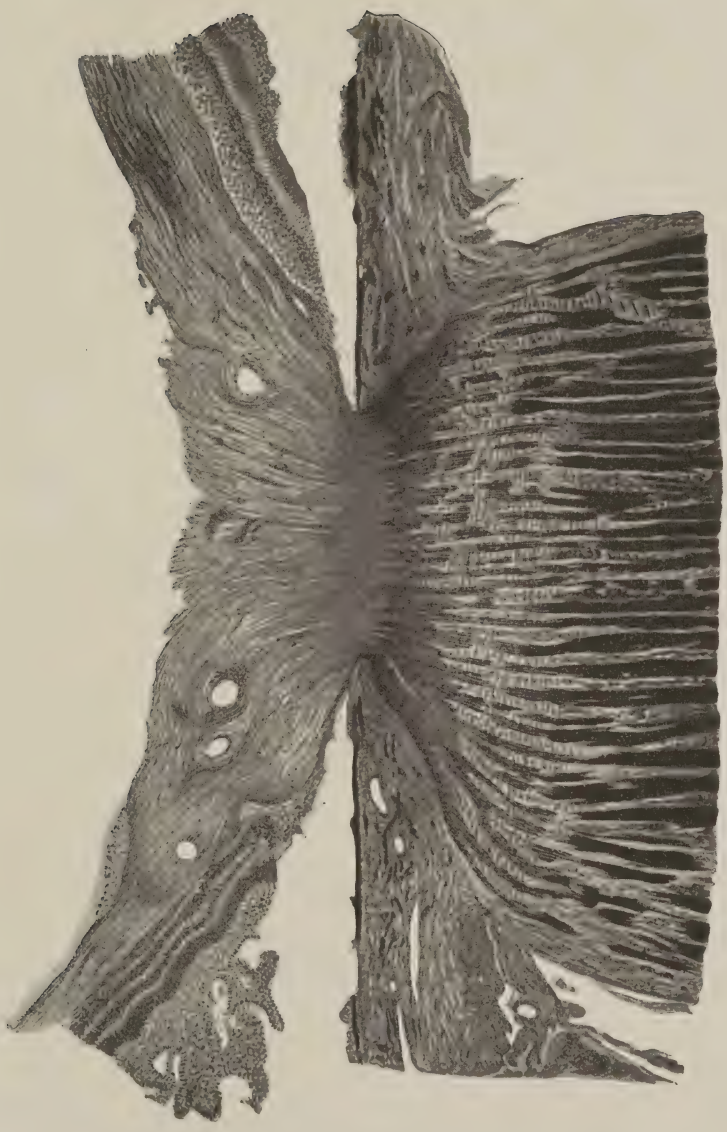
DISEASES OF THE OPTIC NERVE.

Anatomy.—According to Greeff[1] the optic nerve is made up of fibers representing prolongations of nerve-cells found chiefly in the ganglion-cell layer of the retina, terminating finally in the primary optic center of the brain. Other fibers originate in the brain and terminate in the retina. Manz[2] regards opaque nerve-fibers as a congenital malformation. (Pl. 13.)

Drusen, or Glands.—Sachsalber[3] cites a case of drusen in the optic nerves of two eyes otherwise normal. A careful study of the sections indicates that they are the result of hyaline degeneration of the connective tissue in the nerve-head. On the other hand, Gifford[4] considers drusen were the primary cause of blindness in a 9-year-old boy because, by their enormous development, they suppressed the arterial circulation.



Decussation of the Tracts.—Rakowicz[5] questions the existence of nasal hemianopsia, pure and simple, as the result of pressure on both sides of the chiasm. [To attempt to explain the clinical features of hemianopsia in man by anatomic findings in the lower animals seems to us an error. The different arrangement of the optic nerve-fibers in man from that of the lower animals has been too abundantly proved to permit the application of Rakowicz's idea.] Michel and Kölliker go even farther. They assert the total decussation of the optic nerves at the chiasm.[6]

Up to the present time it has been held by all investigators that the **removal of the occipital lobes** of dogs and monkeys causes complete blindness. Vitzon,[7] repeating this experiment on a monkey, observed that the animal began to notice objects again (with much difficulty) about 4 months after the operation, which would indicate regeneration of the destroyed section of the brain. The new substance is nervous tissue, and not hypertrophy of a fragment overlooked. [This is certainly remarkable, since it suggests that regeneration of nerve-elements is possible when nutrition in the organ is preserved.] Vitzon now removed the new structure, and blindness was again produced. After a lapse of 4 months the animal gave evidence of the reappearance of vision. The author explains that the sense of vision improved by the presence of the newly-formed elements.

Toxic Amblyopia.—In experiments on dogs,[8] made by De Bono to determine the changes induced by large doses of quinin, there was found marked contraction of the vessels of the optic nerves, and sometimes complete obliteration without traces of inflammation. The fibers of the nerves were always normal. The vascular contraction sometimes involved the vessels of the iris and choroid. Quinin was found in the ocular fluids, from which De Bono infers direct action of the drug on the vessels and on the rods and

Medullated retinal nerve-fibers (Arch. of Oph., Apr., 1896).

cones, where its effect is to paralyze. Continuing his experiments, he says that in quinin-amblyopia ischemia of the retina is always present in all cases, whether cured or not. He advises iodid of potassium and frequent paracentesis of the anterior chamber to facilitate the quick interchange of the ocular fluids; later, strychnin.

DeSchweinitz observed that dogs given large doses of salicylic acid or salicylate of soda exhibited amblyopia with blanching of the optic disk and contraction of the vessels, resembling that seen in quinin-amaurosis.[1] Conjunctivitis, corneal haze, and even hypopyon-keratitis, may follow injections of this drug. DeSchweinitz[2] shows the microscopic changes in the visual apparatus in dogs artificially blinded are thickening of the blood-vessel walls, the formation of a clot from thrombosis of the optic-nerve vessels, widening of the infundibulum of the vessels, and atrophy of the nerves, optic chiasm, and optic tracts. Masius[3] observed 2 cases of complete blindness following immediately the administration of 8–10 gr. of the ethereal extract of male fern. He gave the drug to 4 dogs, 2 of which became blind.

A child of 4 years was ordered a large quantity of **quinin**[4] to be taken in many divided doses. The powders were given by mistake in rapid succession and caused a profound sleep. Upon awakening the child was perfectly blind and could not distinguish day from night. The ophthalmoscope showed no lesion. Vision returned after a few days. The most effective treatment, according to DeSchweinitz[5] and Demicheri,[6] is cessation of quinin, inhalation of nitrite of amyl, administration of strychnin, hydrobromic acid, and iodid of potassium.

Cervillo's case[7] was one of absolute central scotoma and postocular neuritis due to **stramonium-poisoning.** The patient was a subject of asthma, and smoked cigarettes of stramonium to relieve the attacks; 6 months after discontinuing the habit he was well.

Darde and Vigor[8] observed a number of cases of amblyopia in a company of 135 men who had partaken of infected **veal.**

A rare form of temporary amblyopia following the use of chocolate, either as a confection or a beverage, is brought forward by Wood.[9] The disease occurred in the person of a physician, whose intelligent observation of his own symptoms removed all doubt as to the connection between the chocolate and the blind-spells.

Hilbert[10] records a case of temporary complete blindness from the ingestion of 45 gr. of **acetanilid.** The nerve and retina were anemic and the visual fields contracted. Vision was restored by inhalations of nitrite of amyl and brandy internally.

Miller and Ring[1] describe a case of acute **lead-poisoning** from absorption of particles of metallic lead through the lungs and skin in a patient who made rag carpets from old window-shades. Under milk diet, potassium iodid, and strychnin the vision improved to O. D. $\frac{20}{70}$, O. S. $\frac{5}{200}$, leaving partially atrophic disks.

Reiner[2] reports at some length another instance of toxic amblyopia from the fumes of **carbon bisulphid.**

Barrett[3] comments on the cases of 2 brothers with central color scotomata and gradual failure of sight from optic neuritis, without history other than that each smoked a moderate amount of strong **tobacco.** There was no evidence in either case of intracranial disease.

Brunner[4] refers to a man of exemplary habits who suffered from positive central scotoma in each eye without assignable cause. The scotoma of the one eye grew smaller under treatment, while at the same time that in the other eye enlarged, to disappear later. Mercury and iodid made up the treatment. The condition seemed to be a retrobulbar neuritis or a papillomacular neuritis, hemorrhagic in character and possibly due to **excessive use of the eyes.**

Darier[5] claims to have cured a well-marked case of retrobulbar neuritis, with absolute central scotoma and loss of sensation of that part of the skin supplied by the infraorbital nerve, by subconjunctival injections of 1 : 5000 bichlorid of mercury.

Heinzel[6] adds to his previous report 3 new cases of **amblyopia occurring during lactation.**

Syphilitic Optic Neuritis.—Januszkiewicz[7] divides specific optic-nerve affections into inflammatory and noninflammatory. His study of 150 specific affections of the optic nerve in Hirschberg's clinic, in reference to the interval between infection and the appearance of nerve-trouble, shows that, in general, inflammations follow in about 1 to 5 years, while noninflammatory degenerations appear in from 5 to 10 years after infection.

According to Zimmerman,[8] acute **rheumatic neuritis** is characterized by sudden onset, is monocular, and follows previous exposure to cold. There is typical papillitis, ending with white atrophy, contracted or dilated pupil unchanged by direct action of light, but responsive consensually and with accommodation. [Zimmerman's case and others show that doubts as to the existence of a rheumatic neuritis should be discarded; 2 cases under our treatment had undoubted rheumatic neuritis and lost all light-perception. One case recovered vision after salivation, the other after bleeding at the arm.]

Highet[9] has met with another instance of acute monocular optic neuritis due to **gonorrheal infection.** No other cause could be assigned. Vision, which fell to $\frac{1}{4}$, with indentation of the fields for red and green, returned to

normal under rest, atropin, and the internal use of potassium iodid. Reiss[1] quotes an analogous case, but without recovery. [Inasmuch as rheumatism is often a concomitant of gonorrhea, it would seem that the cases just cited are more or less closely allied in etiology to the preceding ones.]

Neuritis of Intracranial Origin.—Parinaud[2] adheres to his theory, published in 1879, that papillitis of intracranial origin is not due to increased intracranial pressure (Schmidt and Manz), nor to microbic invasion (Deutschmann), but to an edema of the nerve-trunk similar to edema of the brain-tissue: the later inflammation of the retina, common in a neuritis of the trunk, is caused by the presence in the nerve of extraneous material. It is most frequently united with hydrocephalus and increase of intracranial tension, but it does not necessarily imply dropsy of the ventricles. On the other hand, excess of intracranial tension alone is incapable of producing papillary edema. Edema of the nerve does not require any considerable excess of intracranial tension nor mechanical damming up of fluids in the nerve. The intervaginal overflow is a concomitant phenomenon not bearing the relation of cause and effect with a neuritis that could be produced just as well if the intervaginal space did not exist. The scleral ring favors strangulation of the papilla. The external sheath, on the contrary, plays relatively a protective role much as a pressure-bandage. He proposes to call the neuritis of intracranial origin **"edematous neuritis."**

Roghon-Durignaud[3] demurs to Deutschmann's microbe-theory, and, with Schmidt, believes that papillitis is essentially an edema of the optic nerve-sheath due to migration of the cerebrospinal liquid, and not an edema by lymph-stasis in the nerve and brain. Edema of the nerve and retrobulbar subarachnoid space is similar to edema of the limbs from cardiac or renal causes, because circulatory troubles show from the first. If the cause persists, edema may creep up backward as far as the chiasm. The scleral ring, and in less degree the optic canal, are constrictors, and it is this which determines the papillary involvement in the dilatation of the optic sheath between the intracranial region and the globe. He recommends incision into the sheath or trephining the skull in papillitis of cerebral origin, without regard to the site of the lesion, accomplishing by this means drainage.

Adamkiewicz offers another theory.[4] It is generally believed that the intracranial fluid is forced by the presence of the tumor down the intervaginal sheath of the optic nerve, and by compressing the central vein of the retina causes a stasis, the consequences of which are tumefaction of the papilla and edema of the sheath of the nerve. But the optic nerve is compressible, and the fluid can pass into the veins without compressing them. The central vein communicates, through the superior ophthalmic vein, with the veins of the face; it is surrounded with capillaries and is situated in the center of the nerve, and is less influenced by pressure than a number of other veins which are in free communication with the veins of the cranial cavity. By experi-

[1] N. Orl. M. and S. Jour., May, 1896. [2] Ann. d'Oculist., July, 1895.
[3] Arch. d'Ophtal., July, 1896. [4] Zeit. f. klin. Med., 1895; Rec. d'Ophtal., Oct., 1895.

mental increase of pressure in the brain there is stasis of the choroidal veins, but no alteration of the central retinal vein; further, inflammation of the cerebrum and meninges, experimentally produced, does not induce papillary stasis. The author concludes that the stasis is the result of a neuroparalytic optic neuritis analogous to the trophic troubles which are provoked in the eyes of animals by pressure on the occipital lobe.

Elschnig's[1] studies seem to substantiate **Leber's theory** that choked disk arises from an irritation growing out of the presence in the cerebrospinal fluid of noxious elements (toxins introduced by intracranial tumors or inflammations).

Optic Atrophy.—The effects of **lightning** on the eye are not limited to any one ocular tissue. There were partial opacity of the lens, disturbance of the retinal circulation, and inflammation of the nerve in the case recorded by Rohmer.[2] Double optic atrophy was the sequel. Unless there is spontaneous tendency toward cure treatment is of no avail.

Nettleship[3] considers **blindness after head-injuries** to be nearly always permanent, because of optic atrophy. When recovery ensues it is probable that the damage has been caused by effusion of blood into the sheath-space of the optic nerve, rather than by injury to the nerve itself.

From a study of published cases Agella[4] concludes that **fractures** of the anterior section of the base, more than those at the posterior section, are accompanied by paralysis of the optic nerve on the same or opposite side. The nerve is lacerated or torn by rupture of the anterior clinoid processes.

Dombrowski[5] observed **optic atrophy consecutive to carcinoma** of the sphenoid sinus. The affection of the nerve appeared early in the disease, and had proceeded to almost complete atrophy by the time a positive diagnosis had been reached.

A rare history of **atrophy** of the optic nerves as **a sequel to severe hemorrhage** from the stomach is related by Weeks.[6]

Traumatic Atrophy.—The optic nerve was completely destroyed in a patient of Priestly Smith[7] by the penetration of a small rod that entered the orbit through the inner angle of the upper lid. Atrophy ensued.

Embolus.—An embolus, just back of the lamina cribrosa, in a sudden bend of the artery was found by Marple[8] in several of a series of well-prepared microscopic sections. The loss of vision was complete and was followed by glaucoma.

Therapy of Optic Atrophy.—In treatment of double scotoma due to exposure to the direct rays of the sun Sous[9] injected daily-increasing doses of strychnin sulphate into the temples, and vision became normal on the eighth day. Culbertson[10] reports fully 2 cases of optic atrophy in which,

after strychnin had produced only partial benefit, nitroglycerin in doses of $\frac{1}{100}$ to $\frac{1}{150}$ gr. twice daily effected marked improvement in vision. He observes that strychnin frequently induces contraction of the retinal vessels, the very condition of the arteries that often determines the diagnosis. This arterial constriction is nicely met with nitroglycerin, which by its vasodilator action affords the strychnin a much better chance to exert its peculiar effect. It is to this latter fact that the author attributes the favorable influence of nitroglycerin in optic atrophy. [We do not know whether Culbertson's theory can be accepted, but clinically we can substantiate him, for we have several times noted, after the use of nitroglycerin, no little gain in vision in incipient atrophies and also toxic amblyopias, when strychnin was partially or wholly inoperative.]

Tumors.—Ring[1] reports an alveolar sarcoma or carcinoma of the optic nerve in a woman of 47, whose eye on the same side had been removed 1 year previously on account of a painful phthisis bulbi. In all probability the growth originated from the optic nerve-sheath, the inclusion of the nerve being secondary. Weigmann's[2] case occurred in a 5-year-old child otherwise perfectly healthy. The condition manifested itself subjectively by headache and pain on attempts at moving the eye; objectively, by exophthalmos and relative immobility of the globe. The microscopic examination showed a primary tumor of the optic nerve.

Instruments.—Henry[3] has devised a photometer by means of which he gains important information as to the relative light-perception in diseased conditions of the optic nerve, retina, and choroid. In healthy eyes this power begins to decline after 30 years, particularly in hyperopia. It is most diminished in diseases that affect the retina. In albuminuria and diabetes the prognosis is seriously affected by diminution of the power of light-perception.

DISEASES OF THE LENS AND CAPSULE.

Etiology of Cataract.—Baker[4] interrogates all the organs in cases of incipient cataract, corrects all optical defects, and resorts to such general and local treatment as may be indicated. He believes there is a nephritic as well as a diabetic cataract. Myopia and glaucoma have long been recognized as local causes. Stillson[5] fully agrees with Baker. Hess[6] classifies the causes thus: (1) In senile cataract local and constitutional causes are factors; (2) Diabetes is regarded as a typical constitutional cause, since it is not demonstrated that the small amount of sugar in the aqueous and vitreous can account for it; and, like (3) The naphthalin cataract, it is caused by nutritive disturbances; (4) Rarer forms following tetanus, malarial fever, meningitis, syphilis, typhoid fever, lactation and pregnancy, and the use of ergot; Dufour[7] adds to this list influenza, nephritis, and, in children, rachitis and pertussis; (5) Congenital,

[7] Am. Med.-Surg. Bull., May 23, 1896.

due to prenatal diathesis and associated with convulsions, ill-developed teeth, skull, and brain; (6) Choroidal cataract, found in diseases of the uveal tract and in anemia and marasmus, for which the name "starvation cataract" has been suggested; (7) Complicated cataract after inflammations, such as iridochoroiditis, from syphilism, rheumatism, or gout. Hess[1] maintains that every opacity in the lens not traumatic or congenital must find its explanation in some reduction of the body-nutrition. Heredity is mentioned as predisposing to cataract-formation.

Diagnosis of Cataract.—[Estimation of the light-sense as a means of determining the functional activity of the retina and nerve in cases of cataract ready for operation has been employed many years.] Katz[2] offers a refinement of the method. In a thoroughly darkened room a normal eye is closed and light is thrown from a distance of 1 m. With this light held steadily on the eye another light is projected on the closed lid from a distance of 5 m. This is the greatest distance at which any difference can be noted when the second light is covered and uncovered, and forms the standard of measurement. In cloudiness of the media, if the optic nerve be intact the open eye will perceive the same difference when the second light at 5 m. is exposed and covered as is found in the normal eye. If, however, there be any impairment in the function of the optic nerve, the second light must be brought much closer before any difference is noted, and the degree in which the second light must be approximated is the measure of the disability of the optic nerve. Segual[3] has noticed that the pupillary reaction is greater in cataractous than in normal eyes, because the opaque lens diffuses the light over the entire retina.

Extraction of Cataract.—Weeks[4] believes that all cataractous lenses in individuals 25 or more years of age can be removed with comparative safety, and that the most favorable time for the extraction is when the lens-fibers have become separated from the lens-capsule by the formation of liquor Morgagni. He disapproves, accordingly, of Foerster's preliminary iridectomy, preferring simple extraction and removing cortical substance by external manipulation. Derby[5] believes the chances of success in cataract-operation between 80 and 90 years are generally underestimated. Bettmann[6] also prefers the simple extraction. He follows De Wecker's custom[7] in not using eserin, and claims that the results are correspondingly better, and that the use of atropin, eserin, or cocain does not affect the occurrence of prolapsed iris. Nanavatty[8] operates with iridectomy while the pupil is contracted with eserin. To him the ideal operation is extraction of the lens in its capsule, without loss of vitreous, through an intact pupil. Wood[9] discountenances irrigation of the anterior chamber after extraction. He always removes the bandage 24

hours after operation. He feels that immediately after extraction the patient ought to be able to count fingers and *tell time by the watch.* [An unwarrantable procedure, the latter.] Williams[1] recommends a conjunctival suture (employed by his father in 1867), instead of a corneal suture, after extraction, because of quicker healing and less danger of prolapse of the iris. Burnett[2] regards the presence of the capsule in the eye after the removal of the lens as a potent factor in postoperative troubles, and refers 90% of the inflammation, in the iris particularly, to that cause.

Causes of Failure.—Wheelock[3] and Rohmer[4] attribute failure of the operation in many cases to general atheroma of the vessels, and particularly those of the retina. Widmark[5] believes that a faultily-placed incision is the true cause of the keratitis following extraction.

Dressing.—Polyokoff[6] applies immediately after operation a simple starch dressing.

Ellis[7] calls attention to the **rapid ripening** of senile cataracts in some patients. He cites 3 cases in which lenses that had but few streaks of opacity became entirely opaque in less than a week. There was no reason for this sudden change that could be detected before or after extraction. Allport[8] brings forward the unique case of a woman 51 years old, who presented two **nonprogressive,** well-authenticated **hard cataracts** of 25 years' standing, with vision in O. D. of $\frac{20}{200}$, and in O. S. of $\frac{5}{200}$: 21 years previously hard cataract had been diagnosed by Dr. Knapp. With +.75 sph. she did near-work comfortably with her right eye.

Secondary Cataract.—Wickerkiewicz[9] considers secondary cataract operations as serious as the primary.

Postoperative Conditions and Accidents.—Baiaradi[10] finds astigmatism after cataract often dependent upon the method of operation. It is higher in extraction without iridectomy. Anterior synechiæ and prolapse of iris are main causes. Elsberg[11] pictures the insufficient results in discission of secondary cataract, and warns against the pernicious effects on the uveal tract induced by the immoderate use of the needle. He extols highly the extraction of a bit of the capsule by the use of the pincet-scissors, and claims that it is the operation of election. A disastrous result of needling for soft cataract is recorded by Lidbretter.[12] The eye was lost from purulent inflammation. The right eye, on which the same operation had been previously performed with good result, sympathized, and vision was reduced to counting fingers. Eneucleation of the left immediately relieved the inflammatory symptoms. According to Rohmer,[13] the general arterial tension is nearly always exaggerated in arterial sclerosis, owing to hypertrophy of the heart.

[13] Loc. cit.

The *hemorrhage* is at first in the choroid, causing separation of that membrane from the sclera and then from the retina. Another cause is the anatomic relation of the ciliary vessels to the sclera at their points of perforation, where they are held as if by bone, and, having ruptured, there is no chance to retract, and blood escapes into the interior of the globe. Noyes'[1] views are nearly identical. He adds that in cases of high myopia the liability to hemorrhage is greater on account of the fluidity of the vitreous. If the pupil refuses to dilate under atropin, it is because the iris is atrophic. This is an indication for iridectomy. Spaulding[2] also attributes the hemorrhage to sclerosis of the choroidal vessels. Taylor[3] does not hesitate to extract immature cataracts which interfere with vision in persons past middle life, but he is always careful in such cases to facilitate the exit of the lens by a large flap, and to avoid as far as possible the subsequent formation of inflammatory products in the pupillary area by limiting the incision of the capsule, as recommended by Knapp, to the periphery of that membrane.

Congenital Dislocation.—Sous[4] examined a brother and sister with symmetric dislocation of the lenses. Tiffany[5] records a family history of congenital displacement of the lens. Of 9 children, 7 were affected. Lindner's[6] case of ectopia lentis was bilateral and was associated with ectopia of the pupil. Iridectomy with extraction of the lenses was successful in restoring useful vision.

Results of Extraction.—In an analysis of 10,000 cataract extractions Wilson[7] finds an average of $\frac{7}{100}\%$ loss of vision. Previous tables have shown practically the same proportion of loss, notwithstanding the use of cocain and antisepsis in the cases enumerated in Wilson's tables. In another paper[8] Wilson says: "From the purely clinic standpoint of cataract surgery it seems impossible, as yet, to demonstrate any great change in operative results due to the introduction of antibacterial measures." Kayser[9] gives the preference to simple extraction, in which he secures one-third greater vision than by the combined method. Story[10] also finds the average visual acuity higher after the simple operation.

DISEASES OF THE CORNEA.

Physiologic experiments on monkeys made by Turner[11] demonstrate that the Gasserian ganglion has no trophic influence on the cornea, and also that the ophthalmic branch of the fifth nerve may be divided and the ganglion extirpated without risking the destruction of the eye.

Keratitis.—The causes of keratitis are various: thus, the vicious evolution of a tooth, Sous;[12] mould, Fuchs;[13] a small wooden splinter, Fuchs[14]

and Mauthner;[1] traumatism during forceps-delivery, Noyes;[2] pronounced proptosis in exophthalmic goiter, Jessup;[3] tuberculosis, Giglio;[4] influenza, Trantas.[5] According to Randolph,[6] **oyster-shucker's keratitis** is a traumatic infiltration of the cornea, nonvascular, circumscribed, and leaving permanent cicatrices. It is caused by decomposition of the shell lodged in the cornea. There is no specific organism.

Filamentous keratitis, according to Sourdille,[7] is slow in development, subject to relapse, painful, and characterized by long slender excrescences analogous to filaments of twisted silk. In the treatment atropin and cocain should be avoided, and the pedicle of the filament scraped off, a compression bandage worn, and internally quinin and tonics administered.

Interstitial Keratitis.—Trousseau[8] and Trantas[9] believe that interstitial keratitis from *acquired* syphilis is not so rare as is generally supposed. Its course is milder than the hereditary form, shorter in duration, and usually limited to one eye, although these differences are not invariably found. It appears most frequently in the second year after infection, although Trantas' case occurred 13 years after the primary disease. From a clinical study of interstitial keratitis, Cook[10] considers that in the majority of cases this affection of the deeper layers of the cornea is secondary to inflammation of the anterior part of the uveal tract; also that it is due to congenital syphilis. [But we find so many exceptional cases that we are inclined to believe that there must be other causes.] Von Hippel[11] agrees in the main with these views. The etiology, he says, is not well defined, but that hereditary syphilis is undoubtedly the usual origin.

A patient seen by Dunn[12] suffered for several weeks with interstitial keratitis, accompanied with intense photophobia. **Menstruation** was established unexpectedly during the treatment, and the photophobia suddenly disappeared. The corneas cleared only partially.

Denig[13] refers to an interesting case of parenchymatous clouding of the cornea following **lightning-stroke** in a girl 11 years old. There was present almost complete amblyopia and marked blepharospasm. After 18 days the cornea had cleared spontaneously, and the patient regained full visual acuity. Chibret[14] asserts that **parenchymatous keratitis** and exudative choroiditis have a common etiology.

Ulcer.—Three conditions, according to Abadie,[15] are necessary for the development of infected ulcer from traumatism. The cornea must be more or less seriously affected, an infectious agent must be present, and this agent must rest for a certain time in contact with the cornea denuded of its epi-

thelium. Uhthoff and Axenfeld,[1] as a result of a bacteriologic study of 50 cases of suppurative keratitis, conclude that the pneumococcus is invariably the exciting agent in hypopyon keratitis (see Plate 14). It is claimed by these authors that the lacrimal and nasal passages abound with this particular organism. Wood White[2] has found a 4% solution of common salt, used subconjunctively, quite as effective as the different solutions of corrosive sublimate in the treatment of corneal ulcers.

Treatment.—[From the multiplicity of local remedies recommended the inference is naturally drawn that there is no one that will meet the requirements of every case. Of all the special means employed to check the progress and hasten healing of indolent ulcers, we give the preference to applications of strong solutions of silver nitrate.] Abadie[3] believes the most effective treatment is antiseptic washes, subconjunctival injections, and the galvanocautery. Woods[4] applies to the floor of the ulcer silver nitrate in 30 gr. solution. Duncan[5] opens the anterior chamber at its periphery, and keeps the wound open by inserting a probe daily, or performs the Saemisch operation, or applies the galvanocautery and uses eserin. The Saemisch operation or curetting should include healthy cornea. Sachsalber's[6] experiments in ulcus cornea serpens convince him that any procedure that induces long-continued abolition of the anterior chamber may induce glaucoma, and is therefore to be rejected. Especially does he pronounce against Saemisch's idea of paracentesis if the wound is much exposed to the air. Chibret[7] has abandoned the use of the electromagnet and tincture of iodin, preferring methyl violet. Darier[8] also recommends methyl violet and subconjunctival injections. Gallemaertz[9] relies upon ariol, the successor of iodoform; Heuse[10] upon aristol powder; van der Berg[11] upon tincture iodin; Phillips[12] gives the preference to the actual cautery or touching with pure phenol. He [properly] insists that the systemic conditions are not without influence on the course of the disease. Rogman[13] has found "theoform" better than iodoform, boric acid, and all other dry applications.

Hypopyon.—In cases of hypopyon in interstitial keratitis Null[14] considers the only source of the pus is the canal of Schlemm and the small pericorneal vessels, and not filtration through the cornea from the floor of the ulcer. Alt[15] says on this point: "I have never come across any specimen that would tend to show that pus-cells ever do or can pass through Descemet's membrane into the anterior chamber; their only way lies through the meshes of the ligamentum pectinatum." [In the treatment of purulent ulcer and other forms

PLATE 14.

Serpiginous corneal ulcer. The central violet-colored mass is a fibrin plug. The Fränkel-Weichselbaum pneumococcus can be seen between the corneal lamellæ (V. Graefe's Archiv, Bd. xlii., 1896, Part I.).

of purulent inflammation of the cornea eserin is used by many clinicians.] Simi[1] approves of it, on the ground that the benefit to the cornea is greater than the disadvantages of the posterior synechiæ which often ensue after its use. [We have had good results by using both eserin and atropin, the former by day and the latter by night. Posterior synechiæ are in this way avoided.]

Wounds.—Müller[2] states that injuries to the globe occur generally to the nasal or upper aspect of the bulbus, exceptionally to the temporal side; the cornea ruptures oftenest in youth, the sclera in old age. The prognosis is much more favorable in corneal than in scleral rupture.

Tumors.—Pfingst[3] saw a recurrent melanosarcoma occurring in a patient 57 years old as the direct result of a traumatism. Two operations produced a complete cure.

Carr's[4] case of **congenital** opacity of the cornea occurred in a child who was perfectly healthy and presented no evidences of syphilis or any other taint. The parents were both exceptionally sound, and conjunctivitis neonatorum was entirely excluded.

Methods of Improving Vision in Cicatricial Conditions.—The 30 keratoplastics of Fuchs[5] were in general disappointing. They were performed in total abolition of vision in parenchymatous keratitis, complete corneal opacity following inflammation, total staphyloma, and keratectosias, and in only 2 cases was the result at all satisfactory when vision was improved to counting fingers at 1.5 m. In no case did the transplanted flap remain clear. In cases of corneal opacity, when the interference with vision is due to dispersion of rays and not to their total absorption, Van Duyse[6] says that iridectomy does not improve, but materially deteriorates, the vision.

Morton[7] takes even a stronger position as to direct **corneal massage** than last year (see the *Year-Book* for 1896). He still uses his own specially devised spoon, and finds his method as efficient as ever. Wittelshöfer[8] is a strong advocate of massage-treatment.

Conical Cornea.—In the surgical treatment of conical cornea Critchett[9] prefers the galvanocautery to all other measures. Recovery is speedy and almost painless, and the final result satisfactory.

THERAPEUTICS.[10]

Subconjunctival Injections.—[The treatment of ocular disease by means of subconjunctival injections of sublimate and other solutions is a matter that is still *sub judice*. It has become less popular, if we may judge

[10] The space devoted to the subject of Therapeutics is confined to a description of those measures and remedies that are general in their application, and cannot therefore be included in the chapters devoted to the treatment of diseases of any separate part.

by the fewer number of articles written in its favor in 1896 than in 1895. Our own experience with this treatment would not warrant us in recommending it. The favor with which Abadie's suggestions were received is, to us, simply a sad exponent of the inefficiency of whatsoever measure in many inflammations of the deeper structures of the ball.] Schmidt-Rimpler[1] believes it useless in hypopyon-keratitis, diffuse keratitis (parenchymatous), and corneal ulceration [the diseases that were claimed to be most responsive to the procedure]. In iritis and chorioretinitis his results were favorable enough to warrant further trial. In direct and metastatic infection Seggel[2] has had gratifying results. De Wecker[3] claims to cure ulcer of the cornea by large injections of 1 : 2000 solution. In progressive myopia and vitreous opacities De Bourgon[4] found the injections did not clear up the vitreous or arrest the advance of the myopia. Hosch's[5] experience with subconjunctival injections is not especially favorable. When he employs this treatment he injects cyanid instead of the corrosive chlorid. V. Sicher,[6] too, substitutes the cyanid for the sublimate, stating that it possesses all the bactericidal and antiseptic qualities of sublimate, while it produces less irritation of the tissues and less coagulation of albumin. Parisotti[7] claims to have cured 2 cases of beginning panophthalmitis with large injections of bichlorid 1 : 1000.

Other Remedies.—Vian[8] has found **potassium permanganate** useful in affections of microbial origin. He cites 2 cases of purulent ophthalmia cured by the daily application of 10% solution and washing, by the nurse, with 1 : 2000 solution. In abscesses and purulent diseases of the lacrimal apparatus he injects daily a solution of 1 : 100, and obtains rapid cure in all cases. [The tendency of this salt to dissolve the corneal cement must always be borne in mind in applying it to diseases of the eye.] **Pyoktanin,** as an antiseptic, has not proved the efficacious remedy in the hands of Armaignac[9] that Stilling pronounced it. Norsa[10] has employed **pomades of the balsams of Peru** and tolu, 3 : 100, in the treatment of blepharitis, superficial keratitis, nebulæ, superficial and deep corneal ulcers, hypopyon, and dacryocystitis, and is well pleased with their action. He also credits them with a tendency to clear up opaque corneæ. In syphilitic affections Burnham[11] combines daily hypodermic injections of **pilocarpin** with the ordinary mixed treatment, claiming unusual efficiency for it. [For 2 years we have employed this method, and been much gratified with it. Much larger doses of either mercury or iodid can be given with pilocarpin than without it. The increased elimination under pilocarpin renders the cumulative effect of either drug impossible. We are in the habit of ordering diaphoretic measures in connection with the pilocarpin. Careful account of the heart's action should always be

taken before instituting the pilocarpin treatment.] Abadie[1] approves hypodermic injections of 1 % **cyanid of mercury** in place of mercury by the mouth.

Relative Strengths of Mydriatics, etc.—Jackson[2] found that the weakest solutions producing any effect on the pupil were homatropin hydrochlorate, $\frac{1}{30000}$ gr., eserin sulphate $\frac{1}{100000}$ gr., atropin sulphate $\frac{1}{1500000}$ gr., and hyoscyamin hydrochlorate $\frac{1}{3000000}$ gr. Taking homatropin as the unit, the relative strengths of the mydriatics and myotics appears to be—pilocarpin $\frac{1}{4}$, eserin 6, atropin 30, and hyoscyamin 75. Friedenberg[3] reports a case of atropin exanthem extending over the cheek in a girl of 11 whom he was treating for syphilitic iritis.

Chabaneix[4] asserts that **electrolysis,** in feeble current, is the best treatment for stricture of the nasal duct, that it is more efficacious than Bowman's probes employed alone, and that when carefully applied it is not painful.

Arecetin or **arecolin hydrobromate** (probably arcein), isomeric with brucin, obtained from cinchona-bark, is said by Lavagna[5] to possess a myotic action in 1 % solution very energetic, but of short duration. The myosis is complete in 5 minutes, and disappears inside of an hour. Arcein acts on the ciliary muscle, producing a spasm as intense as that of eserin. The author claims reduction of tension in glaucoma after its use. Ohleman[6] found that the pupillary contraction commenced in about 5 minutes, reached its maximum in 10, continued for 20, and vanished in 90 minutes.

The new anesthetic, **"eucain,"** possesses the advantage of not dilating the pupil, and the disadvantage of inducing conjunctival hyperemia (Vinci[8]). As a local anesthetic in all ocular operations excepting those involving the cornea and anterior chamber (where cocain should be used), Bellencoutre[7] recommends, as vastly superior to cocain in destroying sensation, a solution of pure **oil of guaiac,** 1 part to sterilized olive oil 15 parts. The preparation is free from noxious effects. Anesthesia appears in from 8 to 10 minutes after its use and continues 25 to 30 minutes; 2 or 3 drops are sufficient for most operations.

Antipyonin is recommended by Rolland[9] in all forms of conjunctivitis and keratitis, used as a powder insufflated into the sac, and before operations into the nasal cavities. [This is a step in the right direction, and we wish we might see more reference to an attempt at sterilization of the nasal passages before operations on the eye. We believe that neglect of the nasal passages is the source of much postoperative mischief, but accurate knowledge on the subject is not yet at our command.]

[Among the new remedies, none has been so uniformly praised as **formol** (formalin or formaldehyde); 1 : 2000 seems to be the strength most used.] In this strength Lavagna[10] extols it in the treatment of dacryocystitis and as a wash in diseases of the nasal mucous membrane. Barabacheef[11] prefers

formol, in the above solution, to all other antiseptics. In the management of corneal ulcers and hypopyon keratitis Davidson[1] commends formol dropped into the eye every hour. Gepner[2] also gives it his hearty endorsement. [Formol has deservedly won its way to recognition. In all forms of purulent keratitis we employ it with greater confidence than can be reposed in any other one drug; 1 : 2000 solutions used every hour seldom fail to affect an ulcerative keratitis promptly for the better. In purulent conjunctivitis its use in our hands has been less satisfactory.]

For the sterilization of collyria Pagnini[3] relies on a 3% solution of **salicylic acid.** [For this purpose nothing is superior to 1 : 4000 solution of formol.] In order to preserve the yellow oxid-of-mercury ointment from the decomposing influence of light, Holth[4] uses pure lanolin or yellow vaselin as an excipient, and keeps the ointment in dark containers. Luciani[5] advocates the use of **ichthyol** ointment, $2\frac{1}{2}$ to 10% solution, in the treatment of scrofulous blepharitis. Duclos[6] recommends **fluorol,** 1 : 100 or 1 : 200, as an injection into the lacrimal sac and nasal duct in the treatment of dacryocystitis. It is a powerful antiseptic and not painful. In all those conditions of the eye calling for the use of iodoform Hoor[7] gives the preference to **nosophen** (iodol); also when calomel is contraindicated by reason of the internal use of iodin in some form. According to Bates,[8] the effect of instillations of 1% solution of the aqueous extract of the **suprarenal capsule of the sheep** into the conjunctival sac is decidedly astringent, whitening the conjunctiva and sclera, and is not irritating; it is highly extolled in inflammatory conditions and as an aid to cocain before operation. [Our own experience does not warrant its use in inflammatory conditions, but we can endorse Bates's claim that its astringent action is valuable in tenotomy, enucleation, etc.]

THE EYE IN SYSTEMIC DISEASES.

Albuminuric Retinitis of Pregnancy.—Silex[9] finds the ophthalmoscopic picture of renal retinitis and the retinitis of pregnancy quite similar, although in the latter hemorrhages are likely to be more numerous. He believes the amaurosis depends rather on the uremia than upon the edema, and estimates that retinitis occurs once in 3000 pregnancies. The prognosis is worst in contracted kidney, better in acute nephritis, and best in nephritis of pregnancy. Of Silex's cases only those regained normal vision in whom labor was induced. He holds this to be a strong argument for ending the pregnancy. Snell[10] offers the following advice: 1. For retinitis appearing before or about the sixth month induction of labor should be recommended; 2. When it appears only in the last few weeks induction of labor may often be unnecessary, depending upon the severity of each case; 3. A case in which

retinitis shows itself in one pregnancy should be carefully watched, both as to albuminuria and retinitis, in subsequent pregnancies. In young women in whom recurring pregnancies endanger sight the question is raised whether both ovaries should not be removed. Belt's[1] statistics, taken from private practice, on the prognostic value of albuminuric retinitis show that 62% of the cases died within 1 year from the time the retinal trouble was noted; 85% died in 2 years; and 14% lived over that time. Of hospital cases, 85% died within 1 year, 93% in 2 years, and 6% lived over 2 years.

Diabetes.—Among 500 diabetic patients, König[2] found cataract, iritis, ulcer of cornea, keratitis with hypopyon, conjunctivitis, scleritis, tenonitis with chemosis, abscess of lids with gangrene, paralysis of sixth pair, hemorrhagic retinitis with exudation, amblyopia with central scotoma, optic atrophy, homonymous hemianopsia, hemorrhagic glaucoma, limitation of accommodation, ophthalmoplegia externa. Cataract may be safely operated on, provided the patient has been subjected to a dietary course. The grave diseases of the eye are generally followed in a short time by death. Appenzeller[3] found **myopia** of 1.00 D., in connection with an incipient diabetes, that disappeared entirely as the diabetes yielded to treatment. He assumes that the myopia was due to increase of the index of refraction of the aqueous humor.

Hysteria.—The fallacy of the assumption that certain diseases of the eye are hysterical because the diagnosis of organic disease cannot be made from the symptoms is illustrated by Friedenwald.[4] A woman gradually became blind without ophthalmoscopic changes. It was considered by Friedenwald and others (ophthalmic and nerve experts) whom he saw in consultation as hysterical, but the death of the patient some months later showed that she was suffering from organic disease of the brain.

In a youth of 18, Reber[5] cured clonic blepharospasm, at first bilateral, later unilateral, of hysteric origin, by one application of the interrupted galvanic current. He attributes the sudden recovery entirely to the profound psychic effect of the galvanism.

According to Charcot and Parinaud, monocular diplopia in hysteria is always due to spasm of the accommodation. Lagrange[6] asserts that it may have its origin in the brain. His patient was cured by suggestion. A girl of 15 fell on the ice, striking the back part of the head; 4 months later she became entirely blind in the right and partially so in the left eye. No one lesion could be detected, and the diagnosis of hysterical amblyopia, made by Marple,[7] was confirmed by several neurologists. Powers[8] cites a case of hysterical blindness in a married man of 21, who could barely count fingers, but who, after 5 days' treatment with strychnin and potassium iodid, had vision of nearly $\frac{20}{20}$.

Unilateral lacrimation, with limitation of the field on the same side and

the alternation of oversecretion and dryness of the conjunctiva, were seen in hysteric subjects by Berger.[1] An extremely nervous woman, aged 42, under the care of Janet,[2] had transient attacks of hemianopsia and persistence of retinal images. Fixation was first on the left side; afterward she perceived the persistent images only on the right or hemianopsic side, and finally they disappeared, showing the hysterical nature of the symptom. Sensibility was diminished on the right side of the body. Badal[3] cured hysterical symptoms by enucleation of an eyeball. [If we understand by hysteria that a microscopic change, as suggested by Seguin, has taken place in the nerve-elements of the brain in some particular centers, this diagnosis may be made, for the history of these cases and other similar ones would preclude the assumption that the blindness is voluntary or in any way subservient to the will of the patients.]

Epilepsy.—The fundus changes in epilepsy are said by Reber[4] not to be characteristic, and do not differ from those observed in low grades of neuro-retinitis from eye-strain. The same author[5] says that pupillary inequalities are only of relative importance in epilepsy, and can occupy but a minor position in building up the objective picture of that disorder. Ranney[6] reports in full the details of a case of epilepsy in which, after 3 tenotomies of the interni and the correction of the remaining vertical error with prisms, there was complete cessation of the seizures. The treatment extended over a period of 15 months. At the time of report 1 year had elapsed since the last seizure, whereas she had been averaging 2 to 4 convulsions a month for years.

Incipient General Paralysis and Idiocy.—Among the earliest signs of general paralysis are said by Hepburn[7] to be those pertaining to the eyes. The disk assumes a coppery color, or, while it preserves its normal tint, the fundus seems to be infiltrated by a layer of thin fine stripes of a dark color on which the normal vessels run. The disk whitens more and more and excavates slightly; the vessels diminish in size; the temporal and lower borders of the field are the first to become limited; the muscles are weak, especially the internal rectus; the acuity of vision lessens, although the patient declares he can see better than before; finally, an interstitial neuritis may precede all other symptoms for many years. Altabus[8] finds binocular vision the exception in idiocy. He quotes Guibert as observing squint in 60% of the cases he examined. The squint is nearly always convergent, being associated with hyperopia, but in some cases it is divergent. [The frequent occurrence of squint among epileptics and idiots has been commented on by one of the editors of this department when going through the wards of the State Hospital for the Insane at Norristown, Pa. He has shown, too, that the vast majority of epileptics examined there under mydriasis have hyperopia or hyperopic astigmatism.]

Syringomyelia.—A patient of Vialet,[1] aged 57, had muscular atrophy of the left arm with sensory changes. The left palpebral fissure was smaller than the right, the globe retracted, the left pupil myotic and reacted to light and convergence, the right pupil dilated and reacted to convergence, but not to light.

Myxedema.—The eye-lesions in myxedema are, according to Callan,[2] lacrimation due to swollen lids and an appreciable amount of corneal anesthesia. The usual treatment by thyroid extract increases the arterial pressure, already abnormally high, and perhaps induces disease of the kidney accompanied by albuminuria and retinitis.

Ataxia.—Ocular examination in the early stage of locomotor ataxia[3] should include—1. The interior muscles, as shown by the size of the pupils and their mode of response to light and accommodation; 2. The exterior muscles, including the elevator of the lids; 3. The optic nerve, which is so often affected. [In determining the condition of the latter the examination of the field for form and colors is of the first importance, since limitation of the color-field is one of the earliest signs of atrophy.] Of the 103 cases investigated by Grosz,[4] only 13% possessed full acuity and 12% showed normal eye-grounds. Eyes normal in all respects (vision, eye-ground, field, and color-sense) were found in but 2 cases. Normal pupils occurred in 3%, the color-sense was subnormal in 22%, the optic nerve was affected in 32%, and inequality of the pupils was present in 65%.

Hereditary Ataxia.—The ocular complications of hereditary cerebellar ataxia are, according to Longe,[5] progressive and bilateral papillary atrophy, concentric limitation of the field, dyschromatopsia and achromatopsia, equal pupils, neither contracted nor dilated, responding slowly to light and actively to accommodation; nystagmus, paralysis of the external rectus, essentially transitory, and paralysis of the elevator of the lid. The paralysis is not complete and is under the control of the will.

Disseminated Sclerosis.—The ocular symptoms described by Kunn[6] are—nystagmus, produced by fixation or forced peripheral movement; convergence, with loss of movement of excursion from causes in the central nervous system, and not from refractive or muscular conditions; and, finally, failure of near vision.

Syphilis.—Galezowski's[7] divisions of ocular syphilis are—malformation of the protecting coats, paralysis or spasm of the motor nerves, arrest of development, and alteration of the internal membranes. Syphilis is hereditary in the second and third generations. He mentions a large number of cases, particularly of keratitis and choroiditis, which exactly resemble those of acquired syphilis, in which no trace of the poison could be determined. They recover under mercury.

Holth[8] demonstrates positively the possibility of syphilitic autoinfection.

A sailor contracted a bad chancre on the penis that he continually nursed. About the same time a foreign body flew into the eye. For a week he frequently rubbed the eye, and in 3 weeks a typical chancre developed on the margin and conjunctival surface of the upper lid.

Eleneff[1] sums up the ocular complications of encephalic syphilis: optic nerve-affections—papillitis, neuritis, atrophy—are the most frequent. Temporal is more common than homonymous hemianopsia. DeSchweinitz[2] states that hemianopsia, while usually a direct symptom, may be only an indirect sign of the disease or a distant symptom, and that it may accurately localize a very small lesion within the cranium when that lesion is itself insignificant, the main cause being quiescent. Eleneff further says paralysis of the third pair is second in frequency to affections of the optic nerve. It may be partial or complete, the former being more frequent in basal lesions. Internal ophthalmoplegia is common in the mental form of syphilis of the brain. Bilateral chronic external ophthalmoplegia of nuclear origin is seldom due to syphilis. Paralysis of some of the branches of the third pair (unilateral or bilateral) can be satisfactorily explained by a syphilitic lesion of the base. Partial ophthalmoplegia, ordinarily unilateral, is extremely frequent in encephalic syphilis. Paralysis of the other motor nerves is more rare than those of the third, among them that of the sixth occupies the first place. Neuroparalytic keratitis is relatively frequent, and is a sequel of lesion of the Gasserian ganglion. The lesions, in the various ocular complications of brain-syphilis, are in the majority of cases at the base. The meninges are usually affected under the form of gummatous meningitis or more or less diffuse sclerosis. Ewetski[3] saw an instance of relapsing amaurosis due, in his opinion, to gumma at the chiasm. The second attack occurred suddenly and continued 3 weeks. It was followed by bitemporal hemianopsia, hippus, and hemiopic pupillary reaction (Wernicke's symptom). Mixed treatment greatly improved the symptoms; 2 years later there was recurrence with all the symptoms of the second attack. Allyn[4] records a case of left bilateral hemianopsia with loss of accommodation and dilatation of the left pupil. He located the lesion in the right tract between the commissure and optic lobe. Six months later the patient became suddenly unconscious, and upon recovery was totally blind. Vision later improved excentrically, but the scotoma always involved the foveal region.

Intracranial Tumors.—Norris[5] says that papillitis is present in 90% of all cases at some stage of the development of intracranial growths; vision is little interfered with in the early stages; tumors may exist a long time without optic neuritis, when suddenly a vascular storm arising from rapid growth or compression of the large sinuses of the brain may cause its appearance. The papillitis of intracranial growths, characterized by great venous vascularity and swelling, presents an entirely different aspect from the anemic

[5] Univ. Med. Mag., Mar., 1896.

swelling caused by tumors that compress the optic nerves themselves at their passage through the optic foramen. Recurring papillitis in an atrophic disk is very rare, but in these days of trephining is occasionally observed. Norris accords with the opinion that the papillitis is a toxin inflammation.

Convulsions, semiunconsciousness, abolished sensation in the soles of the feet, contraction of both pupils, and nystagmus of the left eye, were noted by Vos[1] as the symptoms of tuberculous meningitis of the left side. Exophthalmos, optic atrophy, paralysis of the 3d, 4th, and 6th nerves, and of the first division of the 5th, severe headache, and death were produced by 3 intracranial gummata—found, postmortem, by Dufour.[2]

Mind-blindness.—Culbertson[3] reports a case of mind-blindness due to cerebral compression, lending color to Swanzy's idea that the center for visual memory lies in the parietooccipital lobe.

Hinselwood[4] reported minutely the results of his examination of a case of **word-blindness.** He calls special attention to the patient's ability to write, but not to read, and on this account believes that there are two centers for perception—that for the intelligent conception for things seen, situated in the posterior convolution of the occipital lobe, and another, which is the center for visual memory, situated in the angular convolution. This patient could recall definitely the shape of any letter shown him; therefore the higher visual memory center was probably not affected.

Optic aphasia accompanying purulent inflammation of the meninges of the left temporal lobe, the latter **the result of a purulent otitis media,** is a complication reported by Jansen.[5] On the fifth day after mastoid trephining his patient named objects, and finally recovered. Urbantschitsch[6] observed nystagmus and dilated pupil caused by ear-disease, and cured when the cause was removed.

Benson[7] records an extraordinary case of **acromegaly** with eye-symptoms. The ocular complications differed from those hitherto reported: 1. The early appearance of central scotoma for colors and probably also hemianopsia for colors; 2. The almost complete recovery of vision which followed the use of potassium iodid and the cessation of tobacco; 3. The return of visual troubles after more than 2 years when the use of tobacco was resumed; 4. The rapid deterioration of vision which occurred when thyroid tablets were first used; 5. The rapid and continued improvement which followed the use of the fresh thyroid extract; 6. The many and peculiar changes which have occurred in the visual field.

Teeth.—The necessity of examining into the condition of the teeth in ocular inflammation is illustrated by 3 cases of Fouchet.[8] The first, of corneal and superciliary cutaneous herpes, seems to have been unquestionably dependent on dental irritation, as all the vesicles subsided in 24 hours after the

[8] Ann. Ophth. and Otol., Oct., 1895.

removal of a decaying molar. The third case was a girl of 21 with monocular optic neuritis and amblyopia. Finally, after extraction of a wisdom tooth while under treatment with mercurial inunction and potassium iodid, vision became $\frac{5}{5}$. [The question remains open whether the removal of the tooth or specific treatment procured the result.] Panas[1] observed a case of blindness, followed by death, from purulent meningitis, secondary to dental caries. The inflammation extended to the maxillary sinus, then perforated the orbital wall, causing orbital phlegmon, and extended into the cranial cavity. The pus found in the cranial cavity contained the streptococcus. Death was probably due to the accompanying erysipelas. Péchin[2] adds testimony to that already in evidence of the serious effect of decayed teeth on the ocular apparatus.

Gout.—The subject of gouty eye-diseases is enriched by a contribution from the pen of Jonathan Hutchinson.[3] They occur intermittently, often once a year, are very painful, but subside completely after a time. The subjects are usually adult men, who, though not liable to podagra, have suffered from sciatica and the like. Aconite, colchicum, opium, and alkalies and liberal counter-irritation are the remedies. A somewhat peculiar form of destructive iritis, usually symmetrical, is occasionally met with in women who inherit gouty tendencies and have arrived at the climacteric period. It is sometimes almost painless. In men, the subjects of acquired gout, we sometimes see acute and very painful ulceration of the margin of the cornea of a definitely gouty nature, and curable by treatment suited to that diagnosis. Women are not wholly exempt.

Under the name of sclerotitis we recognize certain cases almost always associated with arthritis, and often with gonorrheal rheumatism, in which the whole eyeball, as regards its subconjunctival tissue and sclerotic, is congested. There is much irritation and pain. Occasionally the iris is implicated, but the attacks are not, as a rule, attended with danger to the organ. The term "hot eye" is applied to certain cases of temporary congestion of the eye, often quite transitory, to which the gouty are liable. The "hot eye" frequently occurs in direct connection with articles of diet.

Nasal Disease.—Alt's case[4] of optic neuritis consequent upon cauterization of the turbinated bones is not without interest and warning. Alt unearthed a history of syphilis, and believes this established a vulnerability that by reflex excitement from the cauterization developed into a full-blown optic neuritis. [We have now under observation a young woman with large central scotoma in the right eye consecutive to an operation for deviated septum. The blind spot is gradually disappearing.] Laurent[5] has noticed ocular pain and lacrimation as symptoms of nasal disease. Hansell[6] referred

[6] Phila. Polyclinic, May 23, 1896.

acute double optic atrophy in a young man to purulent disease of the ethmoid and sphenoid cavities. In speaking of the ocular symptoms of disease of the mucous cavities of the head, Péchin [1] says: "In some cases the terms 'reflex phenomena' and 'infection' may be connected, but are not inseparable; and in others the reflex phenomena may be the initial symptom of the infection and an inseparable function of it."

Typhus Fever.—In bilateral metastatic ophthalmia following typhus fever Gasparrini [2] seems to prove the necessity for the intervention of the bacillus coli in the production of the ocular and other complications. Toxins of the cultures inoculated in the eye of the rabbit provoked lesions of the uveal tract and of the retina, particularly near the ora serrata.

Measles.—Raymond [3] saw bilateral external ophthalmoplegia and right hemiplegia following measles.

Tubercle.—Valude [4] describes a case of tubercular fungus in an infant, exhibiting swollen lids, chemotic conjunctiva, abundant mucopurulent discharge, pupillary occlusion, and abolition of the anterior chamber; 5 mm. below the cornea was a cavity large enough to permit the introduction of the extremity of the little finger, encircled by red, exuberant fungous borders, filled with pus and communicating with the interior of the globe. The child had congenital abnormalities.

Scorbutus.—Denig [5] reports the following rare condition found in the eye of a scorbutic who was confined to his bed 8 weeks: Papillary edema, narrowed arteries, enlarged veins, numerous hemorrhages along the vessels, and whitish areas about the nerve-head and macula independent of the blood-vessels: 7 weeks later there remained but a trifling edema of the nerve-head and vision was good.

Cirrhosis of the Liver.—Denig [6] observed well-marked venous stasis, narrow arteries, and abundant small hemorrhages along the veins. Icterus was not present. The author attributes the fundus alterations to endarteritis frequently found associated with the arterial changes in the cirrhotic liver. Seabrook [7] calls attention to the importance of interrogating the hepatic functions in ocular disorders of obscure origin, detailing illustrative case-histories.

Diphtheria.—Denig [8] cites an instance of postdiphtheric paralysis of the external recti in a 6-year-old girl. The ciliary muscles and the irides were intact and the eye-grounds normal; 6 weeks later full recovery ensued.

Graves' Disease.—A case of exophthalmic goiter, reported by Friedenberg,[9] is interesting from the fact that the exophthalmos was unilateral, and that the opposite lobe only of the thyroid gland was affected.

SERIOUS INJURIES OF THE GLOBE.

Foreign Bodies.—Hilbert [10] observed a foreign body that had remained

[10] Klin. Monatsb. f. Augenh., Aug., 1895.

imbedded in the cornea for 18 months without producing irritative symptoms. After removal it was found to be a minute bug 1½ mm. in length. Healing of the ulcer was rapid. Jocqs and Fourgs[1] discovered in an eye, enucleated on account of inflammation, a piece of cartridge that had remained in it for the unprecedented period of 40 years.

Wounds.—DeWecker[2] recommends suturing the conjunctiva across the cornea in wounds of the latter. It never becomes united to the living cornea. Vossius[3] sutured the cornea in 3 cases of penetrating wound with entirely satisfactory results.

Removal of Foreign Bodies.—[In the majority of cases the retention of a foreign body in the interior of the ball entails loss of vision and often sympathetic inflammation. The laceration of the tissues and the results of concussion, such as clouding of the lens, detachment of the retina, and rupture of the uveal tract, and the repair process itself, vitiate or destroy function. There are fortunate exceptions to this rule.] Thus, Oliver[4] by the prompt, and Rosenmeyer[5] by the late, use of the magnet restored useful vision. The former advises immediate operation. [It is our experience that delay in the extraction of a foreign body is practically synonymous with loss of sight, and that the magnet to be useful must be employed at once.] Heckel[6] removed, with recovery of vision, a piece of steel and the underlying iris. Holt[7] approves of the use of the magnet in extracting foreign bodies from the vitreous, even if they cannot be precisely located, provided the lesion from the injury is severe enough to cause destruction of vision. Rohmer[8] coincides with this view. He insists that it shall be used at the earliest possible moment, since purulent disease is known to have followed in 2 hours after the introduction of a foreign body into the vitreous. Schmidt-Rimpler[9] prefers Haab's strong magnet for locating and extracting splinters that are hidden in the eye, but when the metal can be seen he prefers Hirschberg's. This is also Hirschberg's own view.[10]

When foreign bodies are small enough to be imbedded in the lens the danger of extraction of the lens is greater than extraction for other traumatic cataracts. Risley[11] warns against the danger of allowing the body to fall back into the eye upon the ciliary region. If it causes no other disturbance than opacity, and if the fellow-eye is good, he advises that it be let alone.

Jackson and Schneideman[12] have decided that in **injury to the crystalline lens,** perforation of the capsule, and disturbance of lens-substance may be followed in the human eye, as in the eyes of lower animals, by permanent healing without opacity, or with opacity strictly and permanently limited to the part directly injured; and this may occur in the adult up to middle life.

Ovio[1] shows by chemic and experimental observation that grains of **lead** in themselves are innocuous, on account of their round form, smooth surface, slight chemic reaction, and aseptic condition at the moment of explosion. That the retention of **glass** is not incompatible with useful vision is shown by Marshall.[2] Corr[3] enucleated an eye that had been injured 3 years previously by an imperfect sky-rocket. At the autopsy a piece of **bone** $\frac{3}{8}$ in. long and $\frac{1}{16}$ in. wide, a portion of the infraorbital margin, was found.

Spontaneous protrusion of a foreign body from the anterior chamber is a rare and fortunate termination of a severe injury. Hansell[4] reports such a case. Armaignac[5] observed the spontaneous extrusion of a piece of **copper wire** that had been resting in an eye for 4 months. Lagrange[6] considers copper less damaging to the eye than other metals, while Leber[7] believes it to be the most noxious of foreign bodies that enter the eye. Badal[8] noticed that grains of **shot** that pass entirely through the eye make the wound of exit exactly similar to the wound of entrance.

The first report of the practical application of the use of the **Röntgen ray** in eye-surgery is made by van Duyse,[9] who detected a grain of lead invisible to the ophthalmoscope. [For Harnisch's investigations with the Röntgen process see section on New Instruments.] Darien[10] finds the ocular media but slightly permeable to the Röntgen rays, and that it is possible that this may be one of the factors of their invisibility.

Rupture.—Fage[11] explains the mechanism of **rupture of the coats** of the ball by the fact that the ball is held between two resisting forces—namely, the wall of the orbit on the one side and the attachments of the optic nerve on the other. Between these two forces the distensible tender membranes rupture perpendicularly to the line of the force.

Tetanus.—Fromaget and Cabannas[12] observed a case in which, 8 days after a penetrating wound of the eye, tetanus of the muscles of the jaw developed, followed by general muscular spasms. The remains of the original eye were enucleated without effect on the tetanus; death followed.

A case of **extensive laceration** of the eyeball, reported by DeSchweinitz,[13] illustrates how we are sometimes happily disappointed by the recovery of an apparently hopelessly injured eye and its restoration to almost complete function. Oliver[14] refers to an injured eye operated on with the electromagnet, which he had observed for 5 years, and which, with the exception of a cataractous lens that could be removed at any time, was perfectly healthy and quiet.

Relative Injuries and Values of the Eyes.—Hoppe[15] shows by statistics that there is little difference in the liability to injury between the right and left eye among all classes of artisans.

NEW INSTRUMENTS.

The Röntgen process has been applied to ophthalmology by Harnisch, who only succeeded in determining the relative resistance of the various parts of the eye to the *x*-rays. They are arranged in the order of their resistance, the most translucent being placed first—capsule of the lens; choroid and retina; sclerotic; cornea; vitreous body; lens.

A new instrument for **discission of the capsule** after cataract-extraction is offered by Weeks.[1] Risley,[2] dissatisfied with most discission-instruments because they cannot be sharpened satisfactorily, uses a small spear-shaped knife, beaten out on the end of the shank and sharp at both edges. The midrib of the spear is very thin, tapering gradually to the point and to either edge.

Basevi[3] has determined **variations in local temperature** after the introduction of various substances into the conjunctival sac. He uses an **ocular stethoscope,** with which he finds a difference in the sound of the straight and oblique muscles during action, likewise a difference between the sound of their action in hyperopia and myopia. He considers the stethoscope a valuable aid in diagnosis. Williams[4] designed a **photometer** to test red signal-lenses and lanterns. It is useful in determining the variation in shade of red lenses used as signals in railroad semaphores, switchstands, etc. A small **electric lamp,** run by a storage battery, all to be carried in the pocket, is used by Mellor[5] for illuminating the cornea, anterior chamber, and lens.

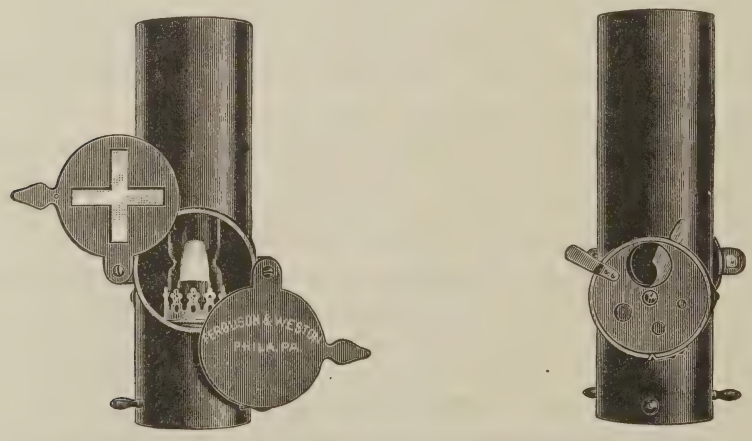

FIG. 150.—Light-screen for use in skiascopy (Ann. of Ophth. and Otol., Apr., 1896).

Zimmerman[6] employs an adjustable Light-screen especially adapted to the **shadow test.** The Welsbach burner is employed in connection with a revolving disk carrying 4 different sized apertures for skiascopy, also a Greek cross for testing muscle-balance at 20 feet (see Fig. 150). Veasey[7] has devised

[7] Jour. Am. Med. Assoc., Mar. 28, 1896.

a **protection-rack** in which a cataract-knife or keratome may be laid for disinfection before operation.

Thoroughly convinced of the practical value of **retinoscopy** in everyday work, Perkins[1] has evolved an apparatus that promises to make the

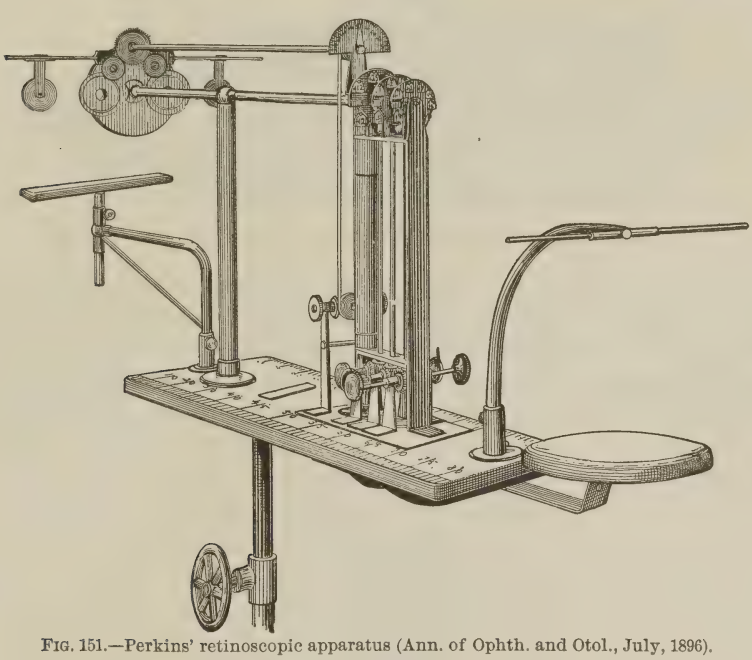

FIG. 151.—Perkins' retinoscopic apparatus (Ann. of Ophth. and Otol., July, 1896).

work of the retinoscopist an easy and convenient task. A glance at the accompanying figure will convey a better idea of the device than the fullest verbal description.

Willetts[2] has devised a **perimeter** constructed of prisms so combined as to form an hexagonal cone. With this hexagonal cone he has demonstrated [to his own satisfaction] that there is no restriction of the normal field for any color or object.

Improvements in **Javal's ophthalmometer** are suggested by Weiland,[3] who advocates the straight arm as being more exact than the arc, since it can measure the corneal diameter in amounts less than a quarter diopter, which the arc cannot do. He makes both mires movable, and brings the edges in contact instead of using steps. The chromatometer he describes may be added to the instrument at slight expense.

Lucciola[4] has made a critical **comparison of the ophthalmometer** of Reid with the instruments of Helmholtz, Javal-Schiotz, and Leroy-Dubois, from which study he concludes that with Reid's instrument one can eliminate the error, common to all the other instruments, arising from the fact that during the examination the visual line does not always coincide with the central

[4] Ann. di Ottal., Ann. xxiv. p. 34.

point of the ophthalmometer. The author commends Reid's device (Fig. 152) in consequence of its small size (4 in. long by $1\frac{1}{4}$ broad), its portability, the precision of its measurements, the invariability of its results, and on

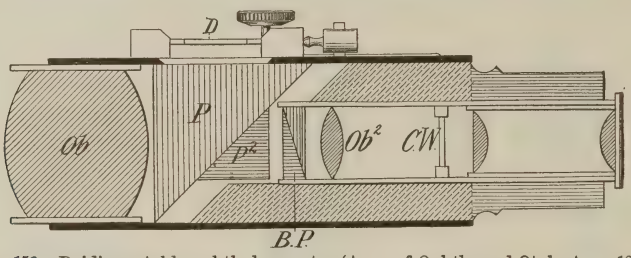

FIG. 152.—Reid's portable ophthalmometer (Ann. of Ophth. and Otol., Apr., 1896).

account of the fact that its usefulness and efficiency do not depend upon a changeable source of light (daylight). Murdoch,[1] who has had more experience with Reid's instrument than any other American worker, gives it his unqualified approval. He believes it to be more scientific and easier of application than the Javal. Its weak point, in his hands, is the difficulty expe-

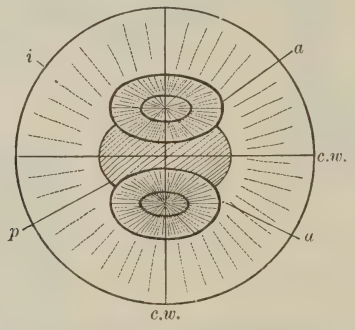

FIG. 153.—Appearance of the corneal images as viewed through Reid's portable ophthalmometer: *a*, annulus; *c.w*, cross-wire; *p*, pupil; *i*, iris (Am. Jour. of Ophth., May, 1896).

rienced in determining the exact angle of an axis against the rule (see Fig. 153).

To measure the angular deviation in muscular anomalies Shirls Jackson[2] has devised a simple, inexpensive, and practical **prismometer** that is a modification of the instrument suggested by Prentice.

OTOLOGY.

By CHARLES H. BURNETT, M. D., and ARTHUR H. CLEVELAND, M. D.,

of Philadelphia.

The More Important Results of the Year's Work.—As to the external ear, the most important fact relates to the extraction of foreign bodies. It is better to let a foreign body in the ear alone than to touch it with an inexperienced hand. The injuries to the patient arising in these cases are the result of unskilful endeavors at extraction—not from the presence of the foreign substance in the ear. In the treatment of acute otitis media asepsis is more important than active antisepsis. The latter is often an irritant, and prevents the ready spontaneous recovery of the acute inflammation by the production of secondary infection of the inflamed middle ear. It is the latter condition, generally a purely artificial one, which induces the dreaded sequelæ—mastoiditis, sinus-phlebitis, and brain-abscess. In the treatment of catarrhal inflammation of the middle ear it will be seen that much remains to be done for the relief of the deafness, tinnitus, and vertigo caused by this disease. The general physician can do very little for the relief of this disorder beyond maintaining the general health of the patient and pointing out the dangers of neglecting proper local treatment. The only advance in the special treatment of this malady and its sequelæ named above has been brought about by intratympanic surgery. By this pathway the advances in the future must be made. Great improvements in the treatment of chronic purulent otitis media have been made—1. By asepsis and drainage of the ear, effected by the surgical removal of necrotic tissue from the drum-cavity, and then by a rational antisepsis impossible before; 2. By exposure of the middle-ear cavities if the first method fails to arrest purulency; 3. By exposure of otitic lesions within the cranium or in the neck and throat, either at the time of, or subsequent to, exposure of the infective middle-ear cavities. It will be seen that, on the whole, the best work in relieving both the infectious state of the middle ear and the resulting otitic lesions in the cranium and elsewhere has been done by aural surgeons. This is due to the fact that they regard both the ear and the otitic lesion elsewhere, and possess the requisite skill to lay bare the middle ear first, and then trace from it the path of infection to the brain or neck without undue sacrifice of tissues essential to hearing, while endeavoring to

expose the life-threatening otitic lesions within the cranium or in the neck. Attention is also called to the fact that many instances of carcinoma of the middle ear have their origin in chronic purulency of the ear. After careful consideration of the notes of a vast number of cases of chronic purulent otitis media and its serious consequences, we are convinced that chronic otitic purulency is generally the result not of neglect, but of infectious treatment.

DISEASES OF THE EXTERNAL EAR.

Congenital Malformations of the Auricle.—Politzer[1] reports a case of bilateral deformities of the auricle in a child of 1, and Downie[2] reports a similar case. On one side there was a distinct supernumerary auricle, but no evidence of an auditory canal in the latter instance. Stetter[3] reports the surgical correction of congenital malformations of the auricle. [Judging from the illustrations accompanying this article, we do not think the cosmetic result warranted the operation. As there was no evidence of the existence of any auditory canal or hearing in the ear operated upon before the operation, no improvement in hearing could be expected from the surgical interference.]

Barkwell and Birkett[4] correct the deformity of prominent auricles by means of the removal of an elliptical space from the back of the ear. In this removal care should be taken to begin from below and to slope the knife gradually sideways till it reaches the widest part of the ellipse. The diameters given were $1\frac{1}{4}$ by $\frac{3}{8}$ in.

Hutchinson[5] maintains that most of the **erosions of the auricle** are due to frost-bites, though some are lupous in character. Max[6] reports a case of **fibrocystic lymphangioma of the helix** of the auricle in a man.

Peck[7] reports a case of **gangrene of the ear** and face complicating pertussis, and Bishop[8] reports a case of gangrene of the ear in a child 2 years old.

Malignant Neoplasms.—Dench[9] reports 2 cases of round-cell sarcoma, 1 of fibrosarcoma, and 1 of carcinoma of the external ear observed and successfully operated upon by him. He states that malignant neoplasms in the external ear are not as serious as in other parts of the body, as shown by the literature of the subject. Denker[10] reports a case of epithelioma of the cartilaginous and cutaneous meatus and auricle in a man of 71, cured by removal of the auricle and curetting the diseased parts of the auditory canal. The meatus was kept open by skin-grafts, and sound thus reached the membrana and middle ear, which were normal. Hennebert[11] reports a case of epithelioma of the temporal bone which seems to have had its origin in traumatism of the auditory canal and neglect of the subsequent purulency.

DISEASES OF THE EXTERNAL AUDITORY CANAL.

Foreign Bodies in the Ear.—Blake[1] records the removal of a piece of gas-carbon from the drum-cavity of a boy of 10, where it had been forced from the external auditory canal by unskilful manipulations before he was seen by Blake. Notwithstanding detachment of the auricle, the foreign substance had to be broken in two before it could be removed from the drum-cavity, where its ends were caught by the tympanic ring. The case made a perfect recovery under antiseptic treatment. Raoult[2] reports a case similar to the foregoing in which a button had been forced from the external ear into the drum-cavity of a little girl of 10. He was obliged to detach the auricle and remove the cutaneous canal from the bone of the auditory canal, as in Stacke's operation. The foreign body was then removed from the drum-cavity, and under antiseptic treatment the child recovered in 3 weeks. Adams[3] records the case of a little girl of 3 who fell with a skewer-like piece of wood in her mouth, and forced the inner end of the stick into the soft parts to the outer side of the anterior pillar of the palate and the inner side of the ramus of the lower jaw, when it broke off. The point ($\frac{1}{2}$ in. long by $\frac{3}{16}$ in. thick) penetrated the floor of the osseous auditory canal, and was finally removed by forceps through the external auditory meatus. The ear was not injured, though the jaw remained restricted in motion a year after the accident. The danger of tetanus in such a case was alluded to by Adams and by Fryer in the discussion following, the latter quoting from a French source the report of a case of tetanus resulting from getting a pebble in the ear. [We saw some months ago a case of fatal tetanus in a boy 12 years old, in which the only possible explanation of the occurrence of the disease was from careless domestic syringing of a chronic purulent otitis media.]

Böke[4] records a case of fatal meningitis set up by unskilful efforts at removal of a foreign substance from the ear of a child $3\frac{1}{2}$ years old. McBride[5] was obliged to detach the auricle and chisel away the posterior and superior wall of the bony canal in order to remove a bean which had been forced into the drum-cavity of a child of 5. Milligan[6] reports 3 cases showing the bad results of rough endeavor to remove foreign bodies from the ear. [If the average medical man would only remember that a simple substance which a child can slip into the external ear could be syringed out by anybody, much trouble would be saved. Gentle measures always succeed, but rough ones never, while the latter always do harm and often cause death.]

Larvæ in the External Ear.—Richardson[7] reports the development of "living larvæ in normal auditory canals." The larvæ were destroyed by instillation of 90% alcohol. Braislin[8] records a similar occurrence in a man of 25. In the latter case the larvæ were probably those of the screw-worm (Lucilia macellaria). There had been no previous suppuration in the ear.

[5] Med. Chron., Feb., 1896.
[6] Ibid., Mar., 1896.
[7] Arch. of Otol., July and Oct., 1895.
[8] Ibid.

The larvæ were destroyed by chloroform-fumes. Barclay[1] reports 3 cases of living maggots in the ear associated with ear-disease.

Local Infection.—Szenes[2] reports a rare case of infection of the external ear from vaccine inoculation. The poison was conveyed from the arm of an infant by the nurse to her own auditory meatus. Recovery ensued in 3 weeks, leaving a characteristic scar in the lower wall of the auditory canal. Scheppegrell[3] reports infection of the ear from picking the canal with a septic toothpick; and Bruck[4] reports a case of syphilitic condylomata surrounding both external auditory meatuses.

Exostoses.—J. Orne Green[5] reports the observation and removal of a cartilaginous exostosis from the meatus. This growth had its attachment by an osseous pedicle to the tympanic attic. After detachment of the auricle from the bony meatus the new growth was seized by toothed forceps and extracted. Under antiseptic treatment of the ear (bichlorid 1 : 5000) suppuration ceased in a month, and in the course of 3 months from time of operation the ear had become normal in all respects. Green has already reported 2 similar cases, and Jack 1. Heretofore these growths were denominated osteomata, but now, adopting the classification of Birch-Hirschfeld, Green prefers to call them cartilaginous exostoses. Max[6] reports for Urbantschitsch an osseous tumor in the auditory canal, similar, apparently, to J. Orne Green's case, and Pritchard[7] has removed successfully an hyperostosis from the auditory canal, partly with hammer and chisel, and finally with a trepan moved by the dental engine. The result was entirely successful. Mathewson[8] records the removal of an exostosis from an ear in 1893 from which he removed a similar formation in 1876. As late as 1885 there was no reappearance. The removal of the exostosis this time was accomplished with a dentist's maxillary "antrum drill," instead of "square drills." The hearing was again restored. Politzer[9] reports the postmortem examination of an exostosis of the auditory canal in a man 64 years old. This growth was supposed to have originated in a previous otorrhea.

Fibroma.—Scheibe[10] reports a fibroma at the entrance of the ear-canal removed successfully with a galvanocautery snare; also, a pedunculated osteosarcoma of the ear-canal likewise successfully removed with the snare. The same writer records 3 cases of "*hairy granulation-tumor* in the *middle ear*."

Carcinoma.—Brieger[11] reports a case of carcinoma of the external ear which began with a pustule in the region of the temple 21 years previous, the ear proper being attacked 10 years previous to his investigation of the case. Kuhn[12] also showed a specimen of a primary cancroid of the auditory canal

in which copious nests of cancer-cells and numerous epithelial pearls were arranged in onion-like layers. In the discussion which followed Kretschmann admits that the diagnosis of cancer, originating in the middle ear, is not to be made solely upon the microscopic revelations, but, in order to avoid errors, regard must be had for the clinical symptoms.

Epithelioma.—Kuhn[1] reports a case of epithelioma in the external ear of a man 61 years old resulting fatally in the course of a year, notwithstanding operation. Krepuska[2] records a case of carcinoma of the external auditory canal, which seemed to have originated in chronic eczema. Carcinomatous degeneration occurred partly in the excretory ducts and partly in the acini of the wax-glands, and extended to the terminus of the middle ear.

Occlusion of the Auditory Canal.—From an article on this subject by Courtade[3] it seems that the preferable way to render pervious the occluded canal is to incise the neoplastic or congenital diaphragm, rather than to excise it around its periphery, and then dilate with drainage-tube and keep clean by antiseptic washes until cicatrization of the cut surfaces takes place with free edges. [A narrow tube of lead-foil makes an excellent dilator until cicatrization with free walls takes place.] Grafting flaps of skin from the concha over the cut surfaces caused by removal of diaphragms in the auditory canal does not seem to repay for the trouble of the operation, as evidenced by Courtade's experiences in this article.[4]

Hearing in Congenital Atresia of the Auditory Canal.—Bezold[5] claims that in cases of congenital atresia of the canal the same symptoms of defective hearing are present as in acquired disturbances in the conducting apparatus, and particularly in fixation of the stapes. He concludes, therefore, that in cases of deformity the cause of defective hearing is not in the inner ear, but in the outer and middle ears.

Traumatic Perforation of the Membrana Tympani.—Politzer[6] states that in traumatic perforations of the membrana tympani the edges are covered with blood, and that air by Valsalva's method passes easily through the perforation, whereas in pathologic perforations blood is absent from the edges, and air does not pass readily through by Valsalvan inflation. Corradi[7] in an article on perforation of the membrana tympani by indirect forces, regarded specially in a medico-legal aspect, claims that perforation from condensation of the air in the external auditory canal is usually found near the center of the membrane, about the lower end of the handle of the hammer, and that perforations from blows on the head without fracture are generally near the periphery. When fracture of the bone occurs the perforation in the membrana tympani depends upon the position, nature, and extent of the fracture. Fetterolf[8] reports 2 cases of traumatic rupture of the membrana tympani.

[7] Arch. f. Ohrenh., vol. xxxix., Nov., 1895. [8] Univ. Med. Mag., Phila., May, 1896.

Fracture of the Malleus.—Fritts[1] reports a case of old fracture of the handle of the malleus with fibrous union.

Cavernous Angioma.—Moure[2] removed a cavernous angioma from the posterior superior part of the drumhead in a woman of 47.

Teeth and Ears.—Barclay[3] calls attention to earache from dental irritation in large children and adults. In all cases of earache in which the tissues of the ear appear normal oral irritation should be sought for, and, if found, removed.

Diving.—According to Koch,[4] the effects of diving upon divers in the German sea service is rarely attended with pathologic results. One case of rupture of the membrane and 1 of otitis media are reported by him.

DISEASES OF THE MIDDLE EAR.

The Middle Ear normally Aseptic.—Lannois[5] has found that the middle ear of dogs is normally aseptic; inferentially, that of man is similar. He also claims that the mucous membrane of the middle ear possesses bactericidal properties, like that of the nasal mucous membrane, as demonstrated by St. Clair Thomson[6] and Wurtz and Lermoyez.[7]

Hemorrhagic Exudation in the Drum-cavity.—Haug[8] reports the occurrence of hemorrhagic exudation in the drum-cavity, as well as of simultaneous hemorrhagic otitis externa from irritation of a pulpitis in a molar tooth. Allport[9] reports the occurrence of myringitis bullosa in a young woman of 20 during an acute coryza. Puncture of the bullæ, the membrana remaining intact, was followed by recovery. Kümmel[10] observed hematotympanum in a case of pseudoleukemia. There was exudation of blood in each attic space, in which the ossicles were imbedded.

Acute otitis media as a complication of pneumonia is described by Ball,[11] and the attention of general physicians called to the fact that the ear-symptoms are often referred to brain-disease. [The cases he reports are well described, excepting so far as concerns the local ear-symptoms: here all is a blank. Of course no relief can be given the patient suffering from ear-symptoms until the ear can be examined with the otoscope, a correct diagnosis then made, and a prompt paracentesis of the membrana performed. Spontaneous evacuation of pus through the Eustachian tube in otitis media does not occur, and cannot be relied upon, as Ball appears to think.]

Acute Otitis Media in Typhoid Fever.—Hengst[12] has ascertained by collective report that in 1228 cases of typhoid fever, 28 had been complicated with acute otitis media. [In February, 1896, we saw the occurrence of acute

otitis media on both sides in a fatal case of typhoid fever which had been treated by cold baths and profuse syringing of the nasopharynx. Causal connection between this treatment and the otitis media was suspected.]

Otitis Media in Infants.—Walb[1] has been making observations upon infants in the Children's Clinic of Bonn with the view of establishing a prophylaxis and form of treatment of suppuration in the middle ear in these young subjects. In order to promote the escape of pus from the ear he recommends the employment of inflation of the nasopharynx. Regarding prophylaxis, in view of the danger of infection of the ear from the nose he recommends cleansing the nose as soon as possible after birth. "This may be done by inflation, one nostril being left open. If infection of the ear is already suspected, inflations should be performed with both nostrils closed." Respecting these very injudicious suggestions, Zaufal wisely remarked that "as the passage of the child from intrauterine to extrauterine life is a normal physiologic process, one may venture to suppose that nature has devised plans whereby this transition may ensue without injury to the child. If, therefore, larger quantities of mucus, etc. are then found in the nose of the child, it is fair to suppose that these will be removed by the establishment of respiration and the movements of sucking and swallowing, without the necessity of artificial help. Under ordinary circumstances, then, there would be no necessity of resorting to inflations. Furthermore, such inflations, even when practised with one open nostril and a small air-bag, are not without danger, because the capacious opening in the child's Eustachian tube favors the entrance of the aforesaid masses into the middle ear, which would produce just what it is desirable to avoid." In some cases a skilful hand may employ inflation, but never should it be done by the laity.

Acute Otitis Media after Removal of Adenoids.—Barr[2] records a case of acute otitis complicated with mastoiditis, following the surgical removal of adenoids from the nasopharynx. He thinks this untoward result was largely due to the irrigations of the nasopharynx carried out before and after the operation. Barr and Brieger both consider such irrigation inadvisable. Galetti[3] observed acute otitis media resulting from tamponade of the posterior nostrils. [In fact, these cases furnish examples of the danger to the ear attending violent measures of any kind in the nasopharynx. Much that is done there does no good to the nasopharynx, while much harm accrues from it to the middle ear.]

Influenza-otitis.—Haug[4] has observed in the last 5 years 214 cases of acute influenza-otitis. In 64 of these the attic or pars epitympanica of the drum-cavity was chiefly affected. The treatment consisted in paracentesis when spontaneous rupture of the membrana did not occur promptly. [It appears that this was not followed by syringing the ear, nor by any applications to the external and middle ears, and the results were uniformly satisfactory, so far as aural treatment was concerned.]

[1] Germ. Otol. Soc.; Arch. f. Ohrenh., Sept., 1895.

[3] Arch. ital. di Otol., Bd. iii.; Zeit. f. Ohrenh., June, 1896. [4] Arch. f. Ohrenh., May, 1896.

Acute Otitis of Measles.—Tobeitz's[1] conclusion, "that in measles, before the appearance of the exanthem, the mucous membrane of the Eustachian tube and middle ear, like that of the respiratory and digestive tract and the conjunctiva, is independently affected, and not by transmission from the catarrhal nasopharynx," has been most thoroughly substantiated by the pathologico-anatomic researches of Bezold and Rudolph,[2] who found in 17 cases of young children, out of 18 examined after death from measles, evidences of acute purulent otitis media. He concludes that in the "great majority of cases the pus in these cases is without symptoms and without any permanent lesion being completely absorbed."

Acute Otitis followed by Mastoiditis.—Holt[3] records 2 cases of acute mastoiditis following acute otitis media, occurring from 3 to 5 weeks previously. Both resulted fatally from intracranial lesions. [We cannot regard the mastoiditis in such cases as a necessary result of the acute otitis media. The only possible explanation of its occurrence is that it is due to septic retention and secondary infection of the mastoid from irritative and infectious local treatment of the ear and nasopharynx, generally before the aurist sees the case.]

Circumscribed Periphlebitis of the Jugular from Mastoiditis.—J. Orne Green[4] reports the occurrence of circumscribed periphlebitis of the jugular due to mastoiditis in a man of 28. The patient had been attacked with acute otitis in the right ear 5 weeks before he was examined by Green, who thinks "the series of pathologic processes were as follows: Suppuration of the tympanum and mastoiditis, periphlebitis (circumscribed pachymeningitis externa) of the lateral sinus, an extension of the periphlebitis down the jugular vein, and, finally, circumscribed suppuration within the sheath of the vein at the seat of operation (by Dr. George W. Gay), some 3 in. below the ear." Before Gay operated for relief of the periphlebitis, finding a little pus within the sheath of the vein, Green had opened the mastoid antrum. The patient rapidly recovered after the operation for relief of the periphlebitis. [It was not stated in the history of the case what had been done by the patient, his friends, or his physician for the ear in the 5 weeks before he was examined by Green. Hence a most important hiatus in our knowledge of the probable etiology of the mastoiditis exists. Mastoiditis is usually an unnecessary artificial consequence of acute tympanitis.]

Purulent Leptomeningitis after Acute Otitis Media.—Joch[5] observed purulent leptomeningitis following acute otitis media, with mastoiditis after measles, in a child 3 years old. The postmortem examination revealed no caries on the inner surface of the petrous bone, but pus was found filling the porus acusticus internus, and it was suggested that pus may have found its way from the middle ear by the way of the facial canal.

Acute Otitis Media followed by Meningitis.—J. C. Oliver[6] records

[1] Ann. f. Kinderh., 1887.
[2] Münch. med. Woch., Mar. 10 and 17, 1896, and Zeit. f. Ohrenh., Apr., 1896.
[3] Am. Otol. Soc., July, 1895.
[4] Ibid.
[5] Arch. f. Ohrenh., Sept., 1895.
[6] Am. Med. Assoc., May 6, 1896.

the occurrence of fatal diffuse meningitis following acute otitis media, the infection having followed the carotid canal into the cranium. [The acute purulency in this case "persisted in spite of treatment," which was conducted over 3 months, when the cerebral symptoms set in. It is very apparent to our mind that the treatment may have been irritative, and therefore largely to blame for the secondary infection of the middle ear and brain.]

Acute Otitis Media; Secondary Infection.—Cases reported by Galetti,[1] Pollack,[2] Mandelstamm,[3] Töplitz,[4] Pritchard,[5] Corradi,[6] Holinger,[7] and Röpke[8] show that secondary infection of the drum-cavity and mastoid in cases of acute otitis media is invariably due to improper—that is, usually excessive—treatment of the primary inflammation.

Septicemia from Acute Otitis Media.—Morra[9] reports a case of general septicemia resulting from acute otitis media, and causing death in 20 days after the occurrence of the acute inflammation in the ear. [No history is given of the treatment of this case in its early stages. Probably secondary infection of the drum-cavity was set up by improper domestic treatment, as often happens before the physician is called in.]

Treatment of Acute Otitis Media and Suppurative Mastoiditis.—Hessler[10] in a paper on this subject states that in acute otitis media when the membrane is imperforate he makes a large curvilinear **incision** in the membrane extending from its anterior border, beneath the malleus, to the middle of the posterior periphery. *Syringing now is strictly forbidden in all acute cases,* and the patient told to mop the ear gently with cotton as often as is necessary to keep it clean. In no instance must the meatus be kept stopped with cotton, as such treatment favors retention of pus. *Inflation of the tympana in the acute stages is strictly forbidden, as this procedure may produce further infection from the nasopharynx.* Boric-acid insufflations are also forbidden, as they become unnecessary as a prophylactic against *infection* from the auditory canal if *syringing be avoided in acute cases.* If secondary inflammation of the mastoid occur, Hessler advises immediate chiselling opening of the process by **Schwartze's method,** suggested for acute cases. By this means all cariously-softened bone is entirely removed from the aditus and antrum by means of the chisel, great care being exercised not to injure the auditory ossicles. The opening in the bone varies from 5 to 8 mm. The wound should not be irrigated, but simply lightly tamponed with iodoform-gauze if there is no parenchymatous hemorrhage: if the latter occur, the wound may be packed more firmly with iodoform-gauze. According to the degree of moisture in the dressings should the latter be changed in 1½ days to 3 days. At such a time any moisture may be mopped from the wound by long strips of sterilized gauze. The auditory canal should be left open. As

iodoform-gauze hinders granulation, the later dressings should be simple sterilized gauze.

In the discussion which followed Panse agreed in the main with Hessler, but thinks that in no instance should patients be allowed to mop their ears with cotton nor use any form of instrument upon their ears, which they never learn to do aseptically. Panse places strips of iodoform-gauze in the auditory canal in cases of acute discharge, allowing the secretion to run into a bandage, which he changes as often as is necessary, and pursues this plan so long as the strip of gauze is moist as far out as the meatus. Barth asserted that the plan of treatment recommended by Hessler has been employed in acute otitis media in Lucæ's clinic for 12 years. [It is strange we have heard so little of so good a plan until Gradenigo and Pes and others have demonstrated that there is no other rational method of treatment in the light of our present bacteriologic knowledge of the origin and course of infection of the middle ear in acute otitis media.]

Stacke states that for 5 years he has operated under strict asepsis, and avoids in acute otitic suppurations not only syringing, but also rough mopping on the surgeon's part, and absolutely no treatment by the patient. Often one dressing of the ear will be sufficient to absorb all the secretion thrown into the auditory canal. After opening the mastoid cavity he prefers to keep the wound open in its outer portions long enough to inspect the deeper parts as long as he may deem necessary.

Leutert stated that in Schwartze's clinic syringing is not done in acute otitis media. It is best, however, to keep the auditory meatus closed in order to prevent entrance of air. Brieger is in favor of dry cleansing with sterilized cotton mops in acute otitis media. A tampon in the auditory canal cannot, in his opinion, lead to retention of pus. But retention of pus may easily ensue in the mastoid wound if healing on the outer side is allowed before healing from the bottom takes place. Hartmann has long ceased to employ inflation in acute otitis media, and has spoken against irrigation of the wound after mastoid-chiselling. A bandage should be retained for a long period only in an aseptic wound, while in septic wounds the dressings should be changed as often as possible. Long-continued tamponing delays healing.

Nolterius does not think that tamponing the auditory canal with absorbent cotton or gauze after paracentesis will lead to retention of pus; after mastoid operations he considers it important to effect healing from the bottom.

Reinhard asserts that in the Schwartze school irrigation is not practised in acute suppurations. Walb considers inflations by either Politzer's method or the catheter as not only useless, but as really dangerous, as by such means pus may be forced into parts of the middle ear previously unaffected, as he pointed out 6 years ago in a meeting of aurists in Heidelberg, and was unanimously endorsed by all present. Burnett[1] warns against the danger of too active interference in cases of acute otitis media, particularly against all forms of inflation during that stage. He thinks that acute mastoid empyema is nearly always

[1] Med. News, Aug. 17, 1895.

caused by improper treatment of acute otitis media, rather than by lack of treatment. Dench [1] outlines the safest treatment of acute otitis by the general practitioner. He calls attention to the fact that no attempt to diminish the quantity of suppurative discharge until the temperature becomes normal and all pain has disappeared should be made. The benefits of the simplest antisepsis in the treatment of acute otitis media, especially by drainage with iodoform-gauze and the avoidance of all irritants, are shown by Fougeray and Vacher.[2]

Tansley [3] has found prompt **incision into the attic** in cases of acute otitis media of great advantage, as recommended and shown by Buck and Sexton many years ago. Tansley adds the excellent advice to close at once, after the paracentesis, the external auditory canal with absorbent cotton [we prefer antiseptic cotton or gauze], and to refrain from douching and syringing. Pritchard [4] insists on the danger of syringing the ear with plain warm water. He drains with cyanid gauze, applying it daily without syringing. Dench,[5] in discussing the treatment of acute inflammation of the middle ear and mastoid, recommends, when bulging of the membrana tympani occurs, early **free incision.** When the tympanic vault is involved, he advises prompt incision through the membrana flaccida, continuing outward, through the tegumentary covering of the superior wall of the meatus, for from $\frac{1}{4}$ to $\frac{1}{2}$ in. When there are mastoid symptoms, he advises the application of cold for 48 hours, then an operation if pain is not relieved by cold. He maintains that wet cups, leeches, blisters on the mastoid, and Wilde's incision are valueless. Barclay [6] discards the use of any form of inflation in acute otitis media, as tending to increase the inflammation, and urges all general practitioners not to permit its use among their patients. Beneficial results of careful **antiseptic treatment** of acute otitis media, after either spontaneous rupture or paracentesis, by means of phenol wash (2%), are shown by MacCuen Smith.[7] Better than antiseptic washes, as above recommended, is drainage of the acutely inflamed and running ear by means of a narrow strip or light tampon of antiseptic gauze in the meatus of the external auditory canal, as shown by Escat,[8] Vacher,[9] and Locoarret.[10]

Otitic Facial Paralysis.—Facial paralysis of the so-called rheumatic variety will generally be found at least associated with acute otitis media, if not caused by it, as shown by Gellé [11] and Lannois,[12] and further illustrated by a case reported by Bundy.[13] [It is highly probable that in 2 other cases of so-called rheumatic facial paralysis reported by Bundy the ear was also implicated, though the otic symptoms may not have been marked.] Trifiletti [14] records a case of **facial** paralysis following inflammation in the ear, which seems to confirm the ideas of Lannois and Gellé that in every case of so-called facial paralysis from cold the middle ear will be found simultaneously affected,

and that the diseased drum is the real cause of the facial palsy. Voss[1] claims to have relieved facial paralysis, the result of acute otitis media in a child, and which had lasted 3 months after all ear-symptoms had subsided, by opening the mastoid and clearing out the hyperemic spongy tissue from the antrum. All other treatment had failed to give relief. It is suggested that in such cases, when all else has failed and not too much time has elapsed since the setting in of the paralysis, the mastoid opening and cleaning out the antrum, as above stated, may be tried with advantage.

Chronic Catarrhal Otitis Media.—MacNaughton-Jones,[2] after careful investigation into the causative relation between hypertrophy of the turbinates and deafness, based upon an examination of 300 cases of aural disease, in which he found only 69 hypertrophies of the turbinated bodies and 18 deviations of the septum, concludes that only in a quarter of the cases aural obstruction can be regarded as causative of deafness. It is his opinion, with which we heartily coincide, that too much and too severe treatment has been directed toward hypertrophies of the turbinated bodies as a means of curing deafness—especially to be condemned is turbinotomy in such connections.

Adenoids.—Arslan[3] in an article on adenoid vegetations in the nasopharynx concludes "that they should always be removed, even when small, and all children, before being accepted into schools, institutions for the deaf and dumb, and other places of education, should submit to a nasopharyngeal examination." In the discussion which followed Helme maintained that the introduction of the finger into the nasopharyngeal cavity after the operation, to assure one's self of the completeness of the operation, is a septic procedure. Gradenigo is opposed to irrigation of this region either before or after operation, especially in children, since, on account of the width of the Eustachian orifice in them, the injections easily enter the middle ear and set up an otitis media: "blood is certainly the best of antiseptics," and should be allowed to flow. In these views Gradenigo was upheld by Brieger. Morse, however, did not share the fears of Helme regarding infection of the lacerated tissues in the nasopharynx by the index finger of the operator. [We side with Helme entirely, believing the introduction of the index finger into the nasopharynx is always a rough, and usually a septic, procedure.]

Thyroid Gland.—Spear[4] claims, as a result of his own observations, that the thyroid gland is "the center of a nervous system which controls, through connections with the sympathetic ganglia and distant nerve-centers by a peculiar inhibition, all the blood-vessels and the center of the circulatory system, the heart itself." He gives a number of cases tending to prove that frequently aural symptoms, tinnitus and deafness, accompanied by enlargement of the thyroid, are due to disease of this latter organ, and are relievable more or less entirely by hot-water applications to the thyroid gland.

[4] Boston City Hosp. Med. and Surg. Rep., 1896.

Senile Changes.—Ferreri[1] has shown that the predominant senile change in the middle ear is atrophy of the bone, particularly of the ossicula, the most important elements in the transmission of sound. Politzer claims that the deafness of old age is due to osseous changes around the oval window, and Masini believes that senile deafness is due to alterations in the articulations of the ossicles, rather than to nervous changes.

Influenza.—Bernstein[2] calls attention to the frequency of serious secondary disease of the ear as a complication of la grippe.

Remote Effect on Eye.—Urbantschitsch[3] calls attention to the possibility of disease of the ear causing disturbances in the motor apparatus of the eye.

Ménière's Symptoms or Phenomena.—[We place the consideration of ear-vertigo, Ménière's disease, etc. under that of chronic catarrhal disease of the middle ear, because we believe that it has been shown that most cases of ear-vertigo, by whatever name they are called, originate in catarrhal disease of the drum-cavity.] Fränkel-Hochwart,[4] Barr,[5] and Gruber[6] have been presenting the old subject of so-called Ménière's disease in a partially new dress. They unite in rejecting the term Ménière's disease for a general one, limiting its use to a particular form of "Ménière's symptom-group." [This, however, is not new with them, as most aurists have long occupied this ground in nomenclature of this malady. Recognizing the fact that ear-vertigo (Ménière's symptoms) may be excited by irritation in either of the divisions of the ear, the outer, middle, and inner, or even in the auditory nerve, we claimed 14 years ago that ear-vertigo should be named according to the seat of the irritation, the term Ménière's disease being reserved for ear-vertigo originating in disease of the internal ear. Tympanic vertigo is that form originating in tympanic disease, and is the most common form of aural vertigo or Ménière's symptoms. By dividing the so-called Ménière's phenomena thus according to the seat of the irritation evoking them, they can be rationally considered and treated, and in no other way.] MacNaughton-Jones[7] describes a case of apoplectiform labyrinthine vertigo, and limits to such an affection the term Ménière's disease. The term Ménière's *symptoms* may be applied to vertiginous conditions evoked by middle-ear disease. In this view he is upheld in the main by Pritchard and Barr.[8] [We advanced the same ideas regarding the different forms of ear-vertigo 14 years ago,[9] and suggested then to limit the term Ménière's disease to vertigo, etc. evoked by a lesion of the labyrinth.] Hyperæsthesia acustica may exist in connection with ear-vertigo, as in a case reported by MacNaughton-Jones.[10]

Lemairey[11] by the use of pilocarpin increased the hearing and abrogated the vertigo and tinnitus in a case of so-called Ménière's disease. Relapses occurring 1 and then 3 months later were cured by quinin.

[10] Loc. cit. [11] Ann. des Mal. de l'Oreille et du Larynx, Nov., 1895.

Ear-vertigo.—Barr[1] describes aural dizziness as due to 4 causes—viz. 1. Ménière's disease; 2. Pressure upon the walls of the middle ear; 3. Pressure upon the walls of the external meatus or outer surface of the drum-membrane; 4. Irritation of the auditory nerve. Reid[2] reports 2 cases of aural vertigo—1 caused by otitis media suppurativa, the other due to adenoid vegetation in the nasopharynx. Treatment of the ear and nose entirely stopped the vertigo in both cases. Gellé[3] draws attention to the fact that general physicians, influenced largely by Trousseau, have long been disposed to attribute vertigo of aural origin to lesion of the stomach, greatly to the detriment of otology and of the patients. In the present day vertigo connected with affections of the nervous system is often confounded with vertigo due to diseases of the labyrinth. He then speaks of vertigo due to diseases of the middle ear, to hemorrhage into the labyrinth, congestion in the labyrinth, anemia of the labyrinth, labyrinthitis, hyperesthesia of the labyrinth, toxemias, and finally of reflex labyrinthic vertigo. He thinks operations in the drum-cavity relieve cases of tympanic origin, while quinin in moderate doses is the best aid in cases of labyrinth origin. Not much aid has been derived by him from pilocarpin.

Epilepsy from Ear-disease.—Verdos[4] maintains that in epilepsy ab aure læsâ there is characteristic aura, beginning in the auditory apparatus, as shown by him in 1891. In fact, every epileptic in whom the aura begins in the ear should be examined by an aurist, who in many instances will give great aid in the treatment. In some cases of manifestly aural epilepsy the aura does not start in the ear, but in one of the extremities; later, however, it appears in one ear, to which fact the patient may draw the physician's attention, as shown by Verdos. This is a very valuable diagnostic sign.

Acoustic Railroad Signals.—Zwaardemaker[5] formulates the following conclusions regarding acoustic railway signals and the hearing power of operatives: 1. At the time of entering the service locomotive engineers and stokers should have at least, on one side, normal hearing or nearly so. 2. Every 2 to 5 years operatives should be reexamined, and their hearing-distance tested with a continuous scale, to see whether the required signals are properly heard. 3. Operatives in the service should be able to hear a whisper at least at a distance of 1 meter.

General Treatment.—Gradenigo[6] claims that the aurist has become more of a surgeon than a physician. Diseases of the external and middle ear are accessible to local treatment. Diseases of the internal ear—otitides internæ—must be reached by general remedies, if by anything. Therefore to institute a rational therapeusis in these cases not only the local aural symptoms must be regarded, but the origin of an affection must be sought, and the history of the patient, of his antecedents, and the previous history of the malady be con-

sidered. Internal otitides are divided by Gradenigo into two categories—those which are due to acquired causes, and those due to heredity. Patients in the second group may be subdivided into—1. Nontuberculous members of tuberculous families (paratuberculous aural sclerosis); 2. Patients whose parents are syphilitic (parasyphilitic sclerosis of Fournier); 3. Patients in families other members of which are affected with similar aural diseases (otitic heredity). Generally, such patients or their parents show symptoms of rheumatism, gout, or arthritis. In the first two groups the patients have generally been affected for many years and from an early age, and the disease is in a "cicatricial" stage when they seek aid. Hence the results of treatment are not brilliant. Therefore, nasopharyngeal affections in children should get prompt and earnest attention. In the discussion which followed Morpurgo[1] maintained that in diseases of the ear the local special treatment is more important than the general, and that inflation of the drum-cavities is not as liable to inflame the middle ears as some authors claim.

Moure[2] stated that even in diabetes surgical intervention in the ears need not be feared. Of course proper general treatment must be carried out at the same time as the local treatment.

Cresswell-Baker stated that he often had employed **pilocarpin injections** in labyrinthitis, but rarely with any benefit. If after the third or fourth injection no improvement is observed, it is best to abandon this treatment. In deafness accompanying myxedema the internal administration of **thyroid gland** has given good results in his hands.

Dundas Grant urged the necessity of a careful diagnosis in order to apply properly a general treatment in ear-diseases, especially a differential diagnosis between organic and functional deafness, as in the latter **pilocarpin** is contraindicated. Corradi claimed that numerous injections of pilocarpin, if applied in the early stages of otitis interna, will give excellent results. Rutten employs in syphilis of the ear **intranasal sprays** of Van Swieten's solution. Delie and Gellé administer the **iodids** in wine mixed with tannic acid, in order to prevent intolerance. Gradenigo in closing the discussion insisted upon the fact that in many instances inflation of the tympana makes the aural disease worse. Randall[3] shows that in "labyrinthine deafness" **inflation** always makes the deafness worse. [We have long observed that inflation of the tympana, frequently applied, will make any form of aural disease worse. It is a shock *no* ear can stand very long.]

Delstanche[4] reports further successes with intratympanic **injections of liquid** (sterilized and sometimes medicated) **vaselin** in chronic otitis media (nonsuppurative), and also in some cases of acute otitis media. In the discussion which followed the views expressed were generally opposed to injections of large quantities of vaseline into the drum-cavity, a few drops being sufficient. Politzer remarked that as he had demonstrated that sclerosis of the

[1] Internat. Otol. Congress; Ann. des Mal. de l'Oreille, etc., Jan., 1896.
[2] Ibid. [3] Polyclinic, Phila., Feb. 8, 1896.
[4] Internat. Otol. Congress; Ann. des Mal. de l'Oreille, Jan., 1896.

ear is caused by primary osseous lesions, it is illusory to expect essential amelioration by intratympanic injections of any kind. [In this we heartily join, and would add that the injection of anything into the drum-cavity, especially a sclerotic one, is likely to excite an acute otitis media.]

Turbinotomy, as suggested and practised by Carmalt-Jones,[1] is not to be regarded with favor as a means of curing tinnitus aurium, according to the experience of MacNaughton-Jones, Bronner, Pritchard, Warden, Baber,[2] and others.

Intratympanic Surgery in Chronic Catarrhal Otitis Media.—Dalby,[3] in referring to operative proceedings upon the tympanic membrane and the cavity of the tympanum for the relief of chronic change, said that "notwithstanding all the disappointments in this direction the fact remains that some of us (and I include myself in the number), after years of careful observation, are still in a position to make a careful selection of cases in which we are reasonably confident that if we could make a permanent and large opening in the tympanic membrane, the hearing would be restored to a most useful extent."

Richey[4] demurs at excision of the membrane and the large ossicula in sclerotic otitis media as irrational, because it does not check the progress of the disease, it deprives the middle ear of its natural protector against incursion of irritants from without, and because it removes only one altered structure in these cases. For, according to Politzer, in these cases of advanced chronic sclerotic catarrh of the middle ear secondary changes have occurred in the bony labyrinth-capsule which are beyond the reach of surgical treatment. The hyperostosis thus caused in the region of the foot-plate of the stapes renders surgical removal of the latter bonelet usually impossible and always valueless. [There are some cases, however, in which relief is given to the tinnitus, deafness, and vertigo of chronic aural catarrh by removal of the incus only, and consequent liberation of the stapes, as shown by Burnett.[5]] Moure[6] concludes that intratympanic surgical interference is of great value in chronic purulent otitis media, but should be practised with great caution for the relief of progressive sclerotic deafness.

Massage of the Middle Ear.—Scattliff[7] draws attention to the advantages of the use of the pneumatic speculum (Siegle's) as a means of applying passive motion to the membrana tympani and ossicula in chronic catarrhal deafness and tinnitus. [This is certainly a rational and safe treatment, and in many cases gives relief, as we can testify from personal experience.] Ear-massage in catarrhal deafness is recommended and carried out in various ways by many aurists. Thus, Randall[8] recommends "pneumatic massage by the finger-tip in catarrhal deafness" as a substitute for so-called "tragus-pressure." [We have for many years observed that patients teach themselves to practise

automassage by finger-tip suction in the meatus for the relief of catarrhal deafness, with fair success.]

"Nerve-deafness."—Dundas Grant[1] has endeavored to establish the clinical existence of so-called "nerve-deafness." In the discussion which followed MacNaughton-Jones[2] regarded the term "nerve-deafness" "a highly presumptive one," and he regards it "from a clinical point of view as in a great many cases the outcome of a purely empirical differential diagnosis." In 50 cases of so-called nerve-deafness specially examined by Jones the causes and symptoms presented indicate the presence of chronic middle-ear disease, at least primarily, if not chiefly, rather than a disease of the labyrinth. If the latter existed, it was purely secondary to tympanic disorders. These last-named affections, including the nasopharynx, should receive prime attention in all cases of so-called nerve-deafness. [The latter term, however, in our opinion, should never be applied to any ear-disease in which the lesion is not primarily in the nerve-structures of the internal ear.] Milligan and Barr[3] maintain that in many cases of so-called "nerve-deafness" the disease is really in the middle ear, and both of these observers, together with Dalby, Woods, Bennett, and others, regard the use of pilocarpin as "useless and unjustifiable" in diseases of the labyrinth. Dalby stated that in many cases electricity gives temporary relief, but this is not usually maintained. ["Primary nerve-deafness" is like "hysterical deafness:" it cannot be shown to occur very often, if at all. Most cases of so-called "nerve-deafness" are found in connection with antecedent chronic catarrhal disease of the nasopharynx and middle ear. These affections of the mucous membrane of the middle ear produce tissue-changes in and about the stapes and round window. Such tissue-changes in the region of the fenestræ compromise to some extent the labyrinth-space and abrogate more or less the readiness of recoil in these safety-points to the pressure from within the labyrinth. Hence any sudden congestion of the head either in the blood- or lymph-vessels is felt all the more quickly and injuriously in the labyrinth on account of its compromised and narrowed state, and lesions of the nerve expanded in it are likely to occur. The patient perhaps now complains for the first time of tinnitus and hardness of hearing. But the lesion, though in the internal ear, is purely secondary to catarrhal disease and consequent trophic changes in the middle ear.]

Syphilitic Deafness.—Downie[4] reports a case of acquired total deafness, the result of inherited syphilis, in a lad of 17. Extensive osseous changes in the middle and internal ears were noted at the postmortem examination.

Deafness of Genital Origin.—Bonnier[5] reports the observance of what he terms intermittent deafness, or rather "variable, profound auditive inattention," affecting both ears, once in an onanist, a girl of 22, and in 2 cases in monorchidic boys (inguinal testicular ectopia). There were no organic changes in the ear in any of these subjects, and there were no other nervous phenomena.

[1] Brit. Med. Jour., Nov. 16, 1895. [2] Ibid. [3] Ibid.
[4] Arch. of Otol., Jan., 1896. [5] Ann. des Mal. de l'Oreille, June, 1896, p. 649.

Trifiletti[1] describes a case of **hysterical aphonia and deafness** in a girl of 18, and Pritchard[2] describes reflex labyrinth symptoms during pregnancy in a subject in whom the same symptoms had occurred in previous pregnancies. These symptoms vanished when pregnancy was ended. Hartmann[3] observed a case of dysbasia hysterica with hysterical otalgia.

CHRONIC PURULENT OTITIS MEDIA.

Local Medical Treatment.—Rauge[4] writes in corroboration of the modern truly antiseptic or aseptic treatment of suppuration of the middle ear, as set forth by Lermoyez and Helme and Gradenigo and Pes, already presented in the *Year-Book* for 1896, pp. 836–840. Somers[5] claims to have obtained very good results from the use of acetanilid as a dusting powder in chronic suppurative otitis media. It is employed after a thorough cleansing with hydrogen peroxid.

Dundas Grant[6] calls attention to the fact that "in cases of chronic suppuration of the ear, apart from severe attacks of pain, even when not yielding to other methods of treatment, extraordinarily favorable effects were obtained by an energetic local use of **alcohol,** a method combining bactericidal and dehydrating effects." Black[7] also advocates instillations of alcohol for the same reasons. Robertson, Macewen, and Pritchard[8] are opposed to **syringing** in chronic purulency as a means of treatment, and especially after mastoid operations. Before removal of granulations and polypi the ear should be syringed with a watery solution of carbolic acid (1 : 40), according to Pritchard. Milligan pursues a similar course before removal of granulations.

In an article on the **neglect of suppurative ear-disease** Erskine[9] condemns postponement of treatment of suppuration of the ear, tamponing the running ear with cotton, the idea of its being dangerous to stop discharge from the ear, the use of the various nostra advertised for the cure of ear-diseases, as there is "no panacea for ear-disease," and recommends that medical students be instructed in clinical otology, and that "the ear should always be examined in the early stage of the illnesses of infants and young children and in all infectious fevers and throat-affections." Dennert[10] recommends the administration of iron and other tonics in cases of stubborn suppuration of the ear. From "humanitarian" motives we should restrict mastoid operations to cases in which they are plainly indicated.

Pes and Gradenigo[11] have shown that the **bacillus pyocyaneus,** often found in otorrhea, is capable of producing an infection of the entire organism, as well as local inflammation in the ear.

Brain-disease.—Michael[12] thinks that "modern aural surgery is directly

responsible for the uncomfortably large number of cases of disease of the sinuses and of abscesses of the brain which are "constantly being published by certain aural clinics." [There is much truth in this, but he should have said *misapplied* aural surgery is to blame for secondary infection of the inflamed middle ear and deeper and more vital parts of the cranium. Both patients and physicians must learn that so-called antiseptic treatment is often not aseptic.]

Surgical Treatment of Chronic Purulent Otitis Media.—Barr[1] reports successful treatment of intractable suppuration of the middle ear by operation through the mastoid, based upon 8 cases. [Two facts of importance are gained by careful reading of this article—viz. first, that all that could have been done through the canal in the form of intratympanic operation was not done, and, secondly, that the *removal of the necrotic ossicula and other diseased tissue from the attic and antrum*, which could have been effected through the canal without the mastoid trepanation, was the true cause of recovery, and not the mastoid operation simply. We feel sure of our position in this matter, because we have seen a mastoid operation alone, *without removal of the diseased ossicula*, fail to cure chronic otorrhea, which, however, promptly yielded to a subsequent operation through the auditory canal for the removal of diseased ossicula and granulation-tissue from the attic. Furthermore, it is now well established that most treatment, by lotions, powders, tympanic syringings through the auditory canal, is infectious, and therefore likely to promote attic and antrum disease, and in all these cases, as reported above, such treatment did no good. Had excision of diseased ossicula been performed through the canal, and infectious washings, etc. been omitted in these 8 cases, it is our belief that they could have been promptly cured without a resort to mastoid perforation.] Bing[2] presents a case of chronic otorrhea cured without extraction of any of the ossicles. No relapse had occurred in 18 months. He, however, advises removal of malleus and incus in stubborn cases of purulent otorrhea as facilitating treatment. Avoledo[3] has presented the results of his experiences in "intratympanic surgery in chronic purulent otitis media." His results are favorable. In the discussion following this paper Ficano asked whether the improvement in hearing following removal of carious ossicula may not be due to mobilization of the stapes. Politzer has observed that section of synechiæ may be followed by permanent improvement in hearing in some cases, while in others the improvement in hearing is only temporary. Marpurgo, while urging conservatism in operating in chronic otorrhea, believes that radical treatment (operative) is followed often by "excellent results." Gellé maintains that in chronic otorrhea the mastoid is chiefly affected, and to that the operation should be directed. [But this is not corroborated by facts.] Gradenigo maintains that an operation should be performed upon the diseased drum-cavity when a careful local treatment applied

[1] Brit. Med. Jour., Nov. 16, 1895.

for several months fails to check the purulency. Moure divides chronic purulent otitides into two classes—those due to lesions in the attic, and those due to disease in the atrium. The second class, "inferior," are healed by ordinary local treatment, while the first class, "superior," due to attic disease, require removal of the ossicula, resection of the posterior superior wall of the auditory canal, etc.

Delie has found the local application of **lactic acid** in tuberculous otorrheas of great advantage.

Urbantschitsch[1] claims that sometimes the **extraction of the malleus** exercises a favorable effect on the hearing in the opposite ear. This is explained by the synergetic action of the tensores tympanorum in man, as in animals. Politzer,[2] however, claims that this explanation is not satisfactory.

Butler[3] records the good effects of **excision of necrotic membrana and ossicles** in chronic suppuration of the ear, as do MacCuen Smith,[4] Lake,[5] and Lichtenberg.[6] The last-named observer operated with great success in a very chronic case of attic suppuration. The hearing was rendered nearly normal.

Carcinoma of Middle Ear.—Danziger[7] reports a case of alveolar epithelioma of the middle ear in a woman of 54 who had suffered with chronic otorrhea in the carcinomatous ear since she was 10 years old. The morbid growth finally invaded the cranial cavity beneath the dura mater of the cerebellum, the jugular fossa, destroyed half of the mastoid region, the external auditory canal, the articular surface of the superior maxilla, and surrounded the carotid. Death, preceded by marked dysphagia, occurred about 6 months after the first symptoms of severe pains in the ear set in.

Sarcoma.—Storey[8] reports a case of sarcoma beginning in the middle ear, and Kuhn[9] observed 2 cases of sarcoma of the ear, not the result, however, of chronic purulency.

Tuberculosis.—Milligan,[10] after an experimental observation respecting "tuberculous disease of the mucous membrane of the middle ear and its adnexa," obtained results which in his opinion prove that "primary tuberculous disease of the middle ear is a much more frequent condition than is usually supposed to be the case." Thus in 10 cases he investigated experimentally, 8 (80%) were of a tuberculous nature, while 2 were nontuberculous. The treatment he advocates[11] is both local and general. The former may be carried out by the application of iodoform powder and packing with iodoform-gauze.

Haenel[12] reports a case of incipient rupture of both labyrinth windows in tuberculous caries of the middle ear. Hyperplasia of bone of the middle ear and foot-plate of the stapes may occur as the result of tuberculosis, as shown

by Bezold.[1] Barnick[2] describes two forms of tuberculous disease of the middle and inner ear—an acute and a chronic one. The former is of rare occurrence, while the latter is common. In the second class of cases the disease is caused by the entrance of disease-germs from the tuberculous nasopharynx, through the Eustachian tube, into the middle ear. [How ill advised, therefore, are all forms of inflation of the drum-cavities in tuberculous subjects!] The painlessness of most cases of tuberculous inflammation of the ear is explained by the "freedom from reaction possessed by the phthisical organism."

Caries.—Bryan,[3] in discussing the surgical treatment of chronic suppurative otitis media, says that chronic perforations situated in the membrana flaccida always mean caries of the ossicles. Abbe[4] reports a fatal case of carotid-artery hemorrhage occurring in a child of $2\frac{1}{2}$ years as a result of middle-ear necrosis. Chronic otorrhea had been present for 1 year. Kretschmann[5] describes a chronic purulency of the middle ear in which the caries is located chiefly in the floor of the drum-cavity in the "recessus hypotympanicus." On account of the proximity of the bulb of the jugular and of the carotid canal to this point this form of purulency in the ear becomes a dangerous one. Wolf[6] proposes to treat this form of purulency by curetting with a sharp spoon the granulations usually accompanying this form of purulency of the middle ear. Meier[7] has observed a case of suppurating thrombus of the bulb of the jugular and of the internal jugular, with granulations of the hypotympanic recess. In the same case the mastoid cavity was found filled with pus and granulations, and, communicating with it, an extradural abscess. Incision into the transverse sinus and cerebellum gave no good results, and death ensued in 2 days thereafter. Panse and Leutert[8] maintain that reinfection of the cavities operated upon in and about the ear occurs through the Eustachian tube, and therefore the former proposes to cause the remnant of the membrana to adhere to the promontory, and thus cut off the passageway from the tube to the drum-cavity. The latter advocates the method now adopted in Halle, of obliteration of the tympanic mouth of the Eustachian tube after tympanic operations in chronic otorrhea.

CHOLESTEATOMA OF THE TEMPORAL BONE.

Leutert[9] describes 2 cases of cholesteatoma—perfect retention-tumors—which were completely closed sacs lined with epithelium and covered outside with a delicate layer of connective tissue. Osteosclerosis of the temporal bone and necrosis of the facial canal near the styloid foramen may ensue in cholesteatoma of the middle-ear cavities, and artificial cholesteatoma may form through the opening retained behind the ear after a mastoid operation, as observed by Grunert.[10] [In general in mastoid cases the less destruction of the cortex the better. Retain the cavity naturally lined with mucous membrane,

rather than convert it into a cavity with a cutaneous lining. The latter is out of place in a closed cavity or one intended to be such.] Redmer[1] shows that cholesteatoma and cholesteatoma-like affections of the cavities of the temporal bone may undergo spontaneous healing by discharging through the external auditory canal. He claims, therefore, that these collections in the temporal bone should be treated by Zaufal's method, without a permanent retroauricular opening, thus agreeing with Vulpius, Hansberg, and Voltenino (see the *Year-Book* for 1896, p. 865).

Treatment of Cholesteatoma.—Randall[2] regards cholesteatoma in the ear as a true neoplasm in all cases; it is "a mass of epidermal debris there collected in a cavity with inadequate exit." He advocates the "masterly conservatism of the Stacke operation, which leaves no external wound, yet by cutting away the tympanic plate and the upper posterior wall of the bony auditory canal over the antrum lays free the attic and antrum for future inspection and treatment if necessary. Of course to perform this operation the auricle and cartilaginous canal must be partly detached and drawn forward over the cheek, the attic opened by chiselling, and the auricle and cartilaginous canal then replaced.

In excision of ossicles and membrana in these cases, through the natural passage, Schwartze seems to have had 40% of cures, whereas in Stacke's[3] operation the cures amounted to 22 in 36, a greater percentage. It must be noted, however, that both of these observers seem inclined to view most cases of chronic suppuration of the ear as fundamentally or potentially cholesteatomatous in nature.] Blau,[4] Steinbrügge,[5] Gomperz,[6] and Locoarret[7] have reported cases of cholesteatoma of the ear. Sheibe[8] maintains that cholesteatoma confined to the drum-cavity is comparatively harmless, but becomes a serious matter if it extends to the aditus and antrum.

MASTOID DISEASE.

Primary Mastoiditis.—Brieger[9] reports a case of primary mastoiditis in a man, followed in 10 days with aural symptoms and abscess-formation in the neck. He states that primary mastoiditis is rare. [We have lately observed a case of primary mastoiditis followed by necrosis of the cortex only, without any aural symptoms, in a boy 5 years old. Resection of the cortex and removal of necrotic cellular substance beneath was followed by recovery, notwithstanding an attack of faucial diphtheria, with formation of false membrane in the mastoid-wound.] Lubet-Barbon[10] reports the occurrence of mastoid abscess without participation of the tympanum. Gellé and Luc[11] are of the opinion that in some cases direct infection of the bone occurs in the mastoid, as in bone-tissue elsewhere in the body.

[10] Ann. des Mal. de l'Oreille, June, 1896, p. 646.
[11] Ibid.

Caries of the Antrum and Mastoid.—Szenes[1] in general advises a most conservative course regarding mastoid operations, having observed many cases in which the symptoms at first seemed to call for this operation, but in which recovery finally took place, in the course of many weeks, without any operation. MacBride[2] is not disposed to regard it necessary to clean out the mastoid as a means of treatment of chronic otorrhea. Shield,[3] too, has found that extensive operations on the mastoid are disappointing in bringing about a perfect cure in chronic otorrhea.

Topography of Skull and Ear.—Both Schülzke[4] and Gaarnault[5] assert that no safe guide in operating upon the temporal bone, so far as concerns the avoidance of opening the middle fossa of the skull and the lateral sinus, can be gained from the topography of the skull, thus agreeing with Randall rather than with Koerner. Moure[6] maintains that a diploic mastoid is frequently found in the adult, and that the lateral sinus lies very near the wall of the auditory canal, and therefore not easy to avoid in operations unless it be first exposed to view, when it can be avoided in further operation in the mastoid region. Condensing osteitis and effacement of the mastoid cells and antrum are the result of chronic suppuration in this region, according to Lubet-Barbon.[7] Therefore, according to him, in cases of eburnation trepanation should be performed forward and upward toward the aditus, as in Stacke's operation, rather than backward toward the sinus. Courtade,[8] like Politzer and many other aurists, maintains that the mastoid participates in most cases in the acute inflammation of the drum-cavity. [But this is no reason why special surgical efforts should be made to draw off the acute purulent collection at that point by aspiration applied through the auditory canal. The siphonic action of a column of fluid flowing from the antrum and middle ear after rupture of the drum-membrane empties the mastoid cavity, if secondary infection of the perforation of the membrana and middle ear is not set up by irritative treatment.]

Knapp[9] presents indications for **mastoid operations** in acute purulent otitis media, with illustrative cases. [These papers are full of interest and important observations. It is very plain, however, to our minds, that had the ears been properly treated in the acute stages, the mastoid complications would never have arisen.]

Mastoiditis with Spontaneous Perforation of the Medial Plate in the Digastric Groove.—Holt[10] and Dench[11] report cases of this form of spontaneous perforation of the medial plate of the mastoid process in the digastric groove. Burnett[12] observed and reported a case of spontaneous perforation of the medial plate of the mastoid, with burrowing along the digastric groove and into the posterior pharyngeal region, with pyemic symptoms, all apparently the result of a badly-treated acute otitis media 8 months previous. Infectious

[12] Phila. Polyclinic, Nov. 23, 1895.

treatment of the acutely inflamed ear by nitrate of silver, hydrogen dioxid, boric acid, applied with mops, etc. insufficiently sterilized, led to secondary mastoiditis. The latter was then neglected with the above results. When the patient was first seen by Burnett distention of the buccinators forced pus from the floor of the auditory canal, and inflation of the tympanum forced pus and air-bubbles from an opening in the neck behind the sternomastoid muscle. The pus-cavity in the pharynx behind the superior constrictor was evacuated by Keen through an incision beneath the jaw, the mastoid cortex being first chiselled off and the antrum exposed. The patient recovered, under scrupulously antiseptic treatment, in 2 months, and the hearing in the course of 6 months improved from 0 to 10 feet for ordinary sounds.

If in operating upon the mastoid the cells of the tip of the process are found full of pus, Dench[1] advises, besides thorough removal of cortex, a detachment of the insertion of the sternomastoid muscle, so as to facilitate complete digital examination of the medial plate of the mastoid in the digastric groove.

In a case of perforation of the medial plate of the mastoid process—sometimes called **Bezold's mastoiditis**—observed and reported by Mendel,[2] the patient was able to force pus from the drum-cavity by pressure upon the swollen and tender region beneath the tip of the mastoid.

Mastoid in Diabetes.—Urquhart[3] reports 2 cases of abscess in the mastoid region, associated with diabetes mellitus. In but 1 of these was the bone involved, and in that there was only unhealthy appearance, but no caries. Körner[4] claims that in diabetics inflammation of the ear and mastoid may occur suddenly, and that when the mastoid is thus affected the condition of the bone is revealed by percussion. When changes have taken place within the mastoid cavity a dull percussion-sound is given out from the diseased side, while the unaffected side gives out the normal hollow sound. Mastoiditis in diabetics may be treated about as successfully as in any other subjects of a dyscrasia, as shown by cases of this nature reported by Buck.[5]

Antrum-disease.—Blake[6] reports 2 cases of antrum-disease—1 in a boy of 10, the other in a woman of 52. In both instances there was a history of acute otitis media a short time before. The discharge had ceased, but pains returned and persisted. In both cases the antra were opened by means of drill and chisel, and small congested areas of bone discovered and curetted, with entire and permanent relief.

Spontaneous Rupture of the Mastoid Cells.—Bacon[7] records the occurrence of spontaneous rupture of the mastoid cells in a girl 2 years old. [According to our experience, most mastoid abscesses will thus relieve themselves in children, and often in adults, without any interference on the surgeon's part. If the primary otitis media is not secondarily infected by too much treatment through the external ear, there will be no mastoid sequelæ.]

[1] Am. Jour. of Obstet., June, 1896. [2] Ann. des Mal. de l'Oreille, June, 1896, p. 659.
[3] Med. News, Mar. 21, 1896. [4] Zeit. f. Ohrenh., June, 1896.
[5] Am. Otol. Soc., 1895. [6] Ibid. [7] Ann. des Mal. de l'Oreille, Jan., 1896.

Involuntary Opening of the Lateral Sinus.—Chincini [1] reports 4 cases of involuntary opening of the lateral sinus during operations on the mastoid process. The hemorrhage was stopped by plugging with iodoform-gauze and sublimate dressing. Recovery ensued in from 6 to 10 weeks.

Auscultation of the Mastoid as an aid in diagnosis of deep lesions, as suggested by Okuneff,[2] seems to have no practical value.

Hysterical Mastoiditis.—Sheppard [3] describes what he terms hysterical mastoiditis, but from the 3 cases reported it would appear that the malady was only otalgia in neurotic women, made worse by their own manipulations of the external ear.

Brieger [4] claims that the presence of **tuberculous mastoiditis** cannot be proved by inoculation of matter from the mastoid, as the animals inoculated die of pyogenic processes.

Mastoid Sarcoma.—Kirchner [5] reports a case of sarcoma of the mastoid cells occurring in a man of 48, long the subject of chronic purulent otorrhea, thus adding another instance of the probable causative connection between sarcoma of the temporal bone and chronic purulent otitis media.

Ferreri [6] reports 2 cases of **epithelioma** of the temporal bone, and Gradenigo 1 case, apparently thus connected with chronic purulent otorrhea. Gradenigo and Politzer both reported the observance of carcinoma originating in the mastoid and passing to other parts of the ear.

SURGICAL EXPOSURE OF THE MIDDLE-EAR CAVITIES.

Grunert [7] contributes a valuable brochure on this subject, which he divides into three parts—viz. pathological, clinical, and experimental. His statements are based on the observation of 209 cases of chronic purulent otitis media in the clinics of Halle. The object of throwing all the middle cavities into one is, according to Grunert,[8] to "essentially favor the cure of the suppuration. Its chief advantage over simple perforation of the mastoid (Schwartze's method, universally employed in acute cases) lies in the possibility it affords to remove more completely all macroscopically diseased tissue, and subsequently to directly observe the throwing off of those diseased portions not sufficiently demarcated at the time of the operation. Even in those cases in which a permanent cure of the otorrhea is not obtained a prophylaxis is given the patient, because anatomic conditions are obtained by the operation which reduce to a minimum, even if they do not confer absolute immunity from, the risks of further pus-retention and the dangers to life connected therewith."

Removal of the Stapes.—According to Grunert,[9] removal of the stapes at the time of exenteration of the drum-cavity for the relief of chronic purulent otitis media is not necessarily followed by injury to hearing nor an

[9] Ibid., p. 221.

intracranial lesion. [Nevertheless, removal of a stapes from a purulent ear resembles opening a door for the entrance of a flood of pus to the internal ear, and we should not like to have it done to us if our ears were affected with chronic purulency.] The desired object of the after-treatment is the complete epidermization of the common cavity formed by surgical means, of all the middle-ear cavities and the external auditory canal, and also closure of the tympanic end of the Eustachian tube (Grunert).[1] This is best obtained, according to Grunert,[2] by firm tamponade with simple sterilized gauze.

Bronner[3] reports 5 cases of disease of the attic treated by **modified Stacke's operation.** [In all of these cases of chronic purulent otorrhea there is a time when they could be cured by excision of the necrotic membrana and ossicula and the removal of synechiæ and granulations. In all cases, at any stage, this should be tried before resorting to exposure of the middle-ear cavities by any form of mastoid operation. In many cases the latter operation would then become unnecessary.]

Hartmann[4] claims that **in order to expose the attic** to view it is necessary to penetrate the superior-posterior wall of the osseous auditory canal rather than the posterior, which is too near the facial canal to permit of free incision. Castex[5] operates on the mastoid in order to expose the antrum, the aditus, and the tympanic cavity to view in obstinate cases of chronic otorrhea in young subjects, in whom the disease has defied local medication. In the main, he depends upon Stacke's method of exposure of these parts. [We must repeat what we have said elsewhere, that these major operations should not be performed, simply for the cure of chronic otorrhea, until the simpler operation of the removal of necrotic ossicula from the drum-cavity has been performed through the natural meatus.]

OTITIC CEREBRAL COMPLICATIONS.

In a discussion on otitic cerebral complications Macewen[6] stated, as his conclusions, "that neither in its presence nor in its absence is bone-conduction a reliable sign of localization as between cerebral and cerebellar abscess." "In at least two ways tubercle of the middle ear merits our attention in relation to intracranial complications—first, by the fact that tuberculous invasions of the membranes of the brain may occur from the focus in the internal or middle ear; and, secondly, tubercle of the middle ear by its slow disintegrating process lays bare the intracranial contents and exposes them to attacks of pyogenic cocci, whose potency has been increased by the pabulum which the liquefaction of the tuberculous products affords." "Besides invading the cranial contents, tubercle orginating in the middle ear and mastoid antrum and cells may enter the circulation, and when it does it occasionally induces

[1] Arch. f. Ohrenh., May, 1896, p. 233.
[2] Ibid., p. 227.

[6] Brit. Med. Jour., Nov. 16, 1895.

miliary tuberculosis of the lungs or other organ." "These invasions of other parts of the body are secondary to the primary focus in the ear, and if tubercle of the mastoid antrum and cells is to be treated, it must be on the same footing as one deals with a localized tuberculous lesion elsewhere. Except by way of improving the hearing in such cases, little good would be done by removing a small portion of granulation-tissue from the middle ear."

[This is true in a late stage, but there is usually a time in these cases when an operation through the external auditory canal for the removal of all diseased tissue in the middle ear, where the disease originates, would very probably render unnecessary the next statement of Macewen, "that the mastoid process must be freely opened, and the whole of the recesses of the temporal bone exposed, and tubercle fully eradicated." Of course if the disease is not checked while limited to the middle ear, as we maintain it can be, then the deeper cavities must be exposed when they have become invaded.]

"In contemplating the small area occupied by the middle ear and its annexes one cannot avoid being struck by the potency of the forces which may be generated within, and which, under suitable conditions, may not only involve the intracranial contents, but within a few days may destroy the function of the whole cerebrospinal system, or, entering the circulation, induce general toxemia, pulmonary infarctions, or infective gangrenous pneumonia. The middle ear, and especially the mastoid antrum and cells, while in a state of suppuration, act as an incubating chamber beautifully arranged for bacteriological work, such as the cultivation of the various pyogenic cocci. . . . . The access to some of these chambers is difficult by way of the external auditory meatus, while injections by that route will hardly reach them, and may even do harm by disseminating the elements which one wishes to remove. Some of these cells are filled with cholesteatomatous material, in which cocci are protected and preserved quite proof against the small quantities of antiseptic fluids which may reach it, as these merely play over the surface of the unctuous material without affecting the organisms within." "Besides the organisms contained in this store of solid culture-medium, others may introduce themselves, or, more probably, be introduced from without."

In regard to autoinoculation Macewen states that, "besides these sources of infection, one can reinfect the tissues of the middle ear by performing in the midst of swarms of pyogenic organisms operations involving a breach of surface in the layer of protective granulations, and thus expose fresh surfaces to the action of pyogenic cocci. Serious intracranial invasion has followed such septic operations," and he maintains "that one who treats ear-disease can no longer be looked upon as one whose whole duty is confined to the function of hearing. He has to act upon that small area of the temporal bone so as to prevent destruction of the whole organism. Every aurist therefore must be a bacteriologist, and his operations are each of them, whether he wishes it or not, bacteriological experiments."

This valuable communication concludes with the following propositions: "1. Infectious diseases extending to the brain and its membranes or to the

organs of the body from the middle ear and its annexes are preventable; 2. when once these diseases are established in the middle ear, it is necessary to adopt means which will ensure their thorough eradication, and this must be regarded as a prophylactic measure against cerebral invasion; 3. when these diseases have once penetrated into the brain, not only does one require to remove the focus in the brain and that in the ear, but likewise the path between the two by which infection has travelled."

Gradenigo[1] in his report on intracranial complications of acute and chronic purulent otitides first states that the technic of the operation demanded in these cases is fully established, but the diagnosis still presents many difficulties. However, diagnosis is much more surely established of late because of the numerous observations which have been published. He very wisely suggests that every new case should be published, regardless of whether it was operated upon or not, and whether it recovered or not, provided the nature and localization of the aural affection were established and the anatomical lesions noted with care, either during the operation or at the autopsy. In 68 cases of mastoiditis (acute and chronic) operated upon by Gradenigo during the year, 12 presented endocranial complications (17.6 %). The complications numbered 14—viz. 5 extradural abscesses, 2 cerebral, 2 cerebellar, 3 thromboses of the sinus, and 2 otitic meningitides. The 8 uncomplicated extradural abscesses all recovered after operations, as did the 2 cerebral abscesses. The 2 cases of cerebellar abscess and the 2 cases of meningitis died. One case of sinus-thrombosis recovered without ligation of the jugular, 1 succumbed to a cerebellar abscess not recognized before death, and the third case died without any operation, as when first observed the patient was moribund from meningitis and purulent pulmonary foci. "The principal guide in diagnosis is the nature and locality of the aural lesion. All operations for the relief of endocranial complications of otitides should be performed by the aurist rather than by the general surgeon, because the former is better able to inquire into the disease of the drum-cavity or of the mastoid. The surgical operation for relief of an endocranial lesion is less difficult than the radical operation for the relief of chronic otorrhea." The diagnosis of meningitis is easier than that of cerebral abscess. The latter Gradenigo thinks can be positively diagnosed only when the aural lesion is on the left side and when verbal amnesia or aphasia is present. "The diagnosis of cerebellar abscesses is the most difficult. While cerebellar and cerebral abscesses may run a latent course, usually there are observed symptoms of an endocranial disease in affections limited to the temporal lobe or in simple extradural abscesses." Gradenigo has observed marked optic papillitis in 1 case of perisinuous extradural abscess, without thrombosis of the sinus, while he has never observed this symptom in other cases of cerebral abscess and thrombosis. He has also observed "intense earache, hemicrania of the same side, rigidity of the nucha, light opisthotonos, vomitings, fever, with altered vocal sounds caused by mastoid empyema and relieved entirely by operation on the mastoid. It must be borne in mind that an otitis

[1] Internat. Otol. Congress; Ann. des Mal. de l'Oreille, Jan., 1896.

is not always the cause of nervous phenomena occurring with it in the same patient, even if they suggest an endocranial lesion, especially in a young subject."

If the symptoms of otitic complications are not grave, the surgeon may temporize in operating, but if they are urgent and life be threatened, he should operate at once. In the former conditions the mastoid should be opened first, the nature of the otitic disease discovered, and the presence or absence of complications in the adjacent parts of the temporal bone established. If the latter complications exist, the surgeon should proceed at once, if possible, to operate for their relief as soon as they are discovered by the exploratory operation on the mastoid. If they do not exist at that time, he should wait a few days to see the effect of his intervention already directed to the temporal bone."

If there is urgent need of operation and the *diagnosis is fairly established*, the surgeon may in some cases first make a temporary resection of the cranium, and treat the otitic affection by a later operation if at the first operation the endocranial abscess has been discovered. When the diagnosis cannot be clearly established, it is better, even in urgent cases, to first trephine the mastoid in order to decide as far as possible upon the way of further interference. Generally, the sinus and extradural abscess are best discovered and opened by way of the mastoid. In order to discover and open cerebral and cerebellar abscesses Gradenigo deems it inadvisable to choose the mastoid and the tympanic cavity as the way of entrance. It is then better to trephine the cranium at a point corresponding to the supposed cerebral nidus. In this way infection from the suppurating middle-ear cavities is best avoided, and a wider and more convenient field of operation obtained at once. If surgical intervention is urgent and a basis of diagnosis of the seat of a profound abscess is wanting, it is best to open at once the mastoid in order to see whether there are changes there sufficient to aid in discovering the nidus. If the result is negative, then it will be necessary to expose generously the sinus and its curve and the adjacent cerebral and cerebellar dura. In exploration, in the absence of precise diagnostic indications and also of grave symptoms, it is not deemed advisable to incise the dura mater, because cerebral hernia, which sometimes follows, is a serious complication, and one which should not be incurred unless in the presence of immediate danger or when the diagnosis is probable. In other cases intervention should be limited to exploratory puncture and aspiration with a trocar 3 mm. in diameter and to a maximum depth of 3 cm. In one instance Gradenigo thus aspirated fragments of cerebellar tissue, in this way excluding a deep abscess at this point, and *the patient was in no way injured by the intervention.*

In grave cases, even if the exploration with the aspirating needle is negative, the dura should be incised and a bistoury introduced. It is suggested also that the fluid aspirated should be examined under the microscope. The fetid odor of the serous liquid thus obtained in 1 case by Gradenigo led to the diagnosis of a cerebral abscess, subsequently relieved by operation.

In the discussion which followed Pritchard and Goris did not regard meningitis as a contraindication for operation, while Brieger maintained that it was an absolute contraindication.

Marpurgo and Pritchard think the aurist alone may operate in some cases of otitic endocranial lesions, especially in small cities. [In smaller towns the aurist may do it alone, as being better prepared than any local general surgeon, but in many cases the aurist and general surgeon can work well together.] The dental bur propelled by a foot-lathe is the instrument of the future in the opinion of Pritchard and others present at the Congress. Those burs made in Philadelphia were considered the best.[1]

Brieger took the ground that in cases in which the cerebral abscess is accompanied by meningitis lumbar puncture of the spinal arachnoid should be performed. In exploration he prefers the scalpel, though there is danger of a fatal result in its use, especially when a cerebral abscess is on the point of opening into the ventricles. He also thinks it proper to penetrate accessory cavities of the tympanum in a preliminary operation, in opposition to Gradenigo, because by this operation the surgeon may expose the fistulous path from the ear to the brain-abscess, as he has done in 2 cases.

When the diagnosis of brain-abscess is obscure he makes an osteoplastic opening in the skull at the point of election, after having made an osteoperiosteal flap from the temporal bone. After this is done an incision into the dura mater and numerous punctures into the brain may be made, and the flap replaced if the result is negative. If an abscess is found, it is an easy matter to drain the middle-ear cavities.

The prognosis in cerebral abscesses Brieger considers always doubtful, even if the abscess is found and emptied, death occurring sometimes from "toxic paralysis of the heart." Operative treatment of sinus-phlebitis he considers more successful. He cites 2 cases of thrombosis of the cavernous sinus which recovered rapidly after operative opening of the lateral sinus.

Barr[2] presents the following conclusions in his report upon intracranial otitis media: It is possible to operate successfully in endocranial abscesses, whether they be extradural, cerebral, or cerebellar; also in cases of infectious thrombosis of the lateral sinus. It is best to choose the way of entrance through the mastoid, because exposure of these cavities may furnish excellent indications for deeper procedures. For trepanning the skull the dentist's crown-drill is preferable to the trephine or the chisel and hammer. With the former a groove may be run down to the tabula vitrea. The resection may be completed with gouge and hammer. So far, operations upon extradural abscesses have given the best results. During the last 9 years 39 successful operations upon such formations have been reported. In septic thrombosis of the sinus it is deemed advisable by Barr to follow evacuation of the abscess by ligation of the jugular. In cerebral abscesses early exploration with trocar and cannula, and prudent antiseptic irrigations thereafter, are recommended. In mixed cases, in which the diagnosis is doubtful, every way by which the diseased ear

[1] Barr, ibid. [2] Internat. Otol. Congress; Ann. des Mal. de l'Oreille, Jan., 1896.

may determine the locality of a purulent collection, whether extradural or in the cerebral substance, should be explored.

The report ends by propounding the following questions for consideration and discussion: 1. Should the cranium be opened even when there are symptoms of diffuse meningitis? 2. In cases of septic thrombosis of the sinus, besides opening the latter, is it necessary to ligate the jugular? 3. What is the best method of trephining the bone? 4. What is the value of radical operative treatment in chronic purulent otitides? 5. In the endocranial complications of otitides who should be preferred as operator, the otologist or the general surgeon?

Schmiegelow[1] reports an instructive case of endocranial complication of chronic suppuration of the middle ear in a boy of 12. An epidural abscess was found on the floor of the middle cranial fossa, evacuated, and the boy recovered. The symptoms—a slow pulse, subnormal temperature, nausea, dulness of intellect, and headache—were those of pressure from a cerebral abscess rather than of epidural abscess. Schmiegelow had never before found a *slow pulse* associated with epidural abscess alone.

Various Methods of Operation in Otitic Brain-complications.—Körner[2] has made a report on the methods of operating in various otitic brain-complications. He first draws attention to the fact that every intracranial suppuration does not always produce symptoms from which safe conclusions as to its location can be drawn. Autopsies have shown that nearly all otitic brain-abscesses are situate very near the spot of original suppuration in the ear or petrous bone, and often in demonstrable connection therewith. Since nearly always when the abscess is in the temporal lobe the tegmen tympani et antri is diseased and the abscess lies with its fundus against the dura, it is possible, as Körner claims to have shown, in proper cases to unite the emptying of the abscess with the removal of diseased bone.

Jansen also presented a report on the same subject before the same Congress,[3] basing his report upon his own observations and experiences in the Berlin Ear Clinic. During the last few years 148 cases of intracranial suppuration have been observed in this clinic, of which 108 were extradural abscesses, 35 thrombosis of the transverse sinus, and 5 brain-abscess; 96 times the suppuration lay in the posterior fossa of the skull, 38 times in the middle fossa, and 14 times in both fossæ. In the books of the clinic in Berlin 58 cases of sinus-thrombosis are recorded, and 16 otitic brain-abscesses, 9 in the cerebellum and 7 in the temporal lobe.

Perisinuous abscesses have generally been exposed by opening the cranial fossa after chiselling open the mastoid process; in a few instances they have been opened through the middle cranial fossa. In many cases—viz. in those in which the mastoid abscess and the purulent centers in the sinus form one pus-cavity—the latter has been opened without further operation. When such

[1] Zeit. f. Ohrenh., Mar., 1896.

[2] Fourth meeting German Otol. Soc.; Arch. f. Ohrenh., Sept., 1895.

[3] Loc cit.

has not been the form of the abscess, the following method has been pursued: "After the opening of the mastoid process and the antrum the posterior bony wall of the mastoid cavity has been chiselled away until the anterior lateral wall of the sinus has appeared. Exposure of the sinus must be carried forward until healthy tissue is reached, of course within limits allowed by the topographic relations." Deep-lying suppurations in the cranial cavity are reached only after removal of the posterior wall of the mastoid process in its entire extent, best accomplished, in Jansen's opinion, with long-bladed bone-forceps and very narrow chisels. If the abscess extends as far as the jugular foramen, it must be pursued by chiselling away the transverse sinus and, when necessary, by removal of a part of the floor of the posterior cranial fossa. If the part of the sinus-wall first exposed is free from disease, then the posterior cranial fossa must be so far exposed to view as to permit the removal by a raspatorium of the sinus and the dura from the posterior wall of the petrous bone. If no pus is found here, and yet the symptoms of a purulent focus in the posterior cranial fossa continue, then Jansen thinks it is necessary to expose the upper knee of the sigmoid sinus and that part of its posterior horizontal course which joins it. If pus then gushes from the middle fossa or if with continuing symptoms of intracranial suppuration the posterior fossa is found to be free from pus, the middle fossa must be opened, preferably above the linea temporalis. If the opening of the middle cranial fossa is begun by removing the lower part of the squama, inspection of the entire upper surface of the pyramid is made essentially easier. The initial puncture should be made close above the posterior part of the auditory canal, and the opening reach backward from that point several centimeters, and as far forward as necessary. Bone-forceps are best adapted for this operation.

Deep-lying extradural abscesses, which originate chiefly from irruption of pus through the semicircular canals—though sometimes from conveyance of pus along the course of the facial and major superficial petrosal nerves—usually have their center at the point where the posterior limbs of the vertical semicircular canals unite, and burrow along the posterior upper edge of the pyramid, sometimes inward and sometimes outward. Nearly all cases of this kind, as observed by Jansen, originated in acute otitis media. The upper wall of the pyramid, as far as the superior semicircular canal, the posterior upper edge of the same for the same distance, and also the adjoining posterior wall, should be removed with bone-forceps as far as the labyrinth-core. Furthermore, Jansen holds that, in order to ensure undisturbed healing and to avoid burrowing of pus along the acoustic nerve, it is best to follow the exposure of deep labyrinth-abscesses by opening the vestibule. This can be done best by removal of the posterior half or two-thirds of the upper semicircular canal, from behind and above, downward by means of narrow, straight chisels. If necessary, also the lower semicircular canal may be partly or entirely removed, and the vestibule laid open, from behind forward, by removing the posterior half of the horizontal semicircular canal.

In no instance of all the abscesses in the temporal lobe operated upon by Jansen was it possible to find the point of transition of the pus from the temporal bone to the brain, although the position of the abscess was uniformly directly over the tegmen tympani. In all of such abscesses Jansen has removed the posterior and upper wall of the mastoid portion as far as the labyrinth; then, leaving the latter intact, he has removed a part of the squama and the tegmen, and then penetrated as far inward as the mouth of the Eustachian tube and the wall of the cochlea. In this way the field of the operation is made broad and comprehends the deepest points of infection.

Von Bergmann's method of opening the middle fossa of the skull can be used with advantage for exposure of the sinus when symptoms of suppuration in the middle cranial fossa are prominent, and subsequently it becomes plain that suppuration has spread to the sinus. In general, the plan presented already for the exposure of perisinuous abscesses may be pursued for laying bare the sinus. The thrombotic part of the sinus should be opened forward and downward until undiscolored thrombosis is reached—if necessary as far as the region of the jugular foramen. Backward it is better to proceed a few centimeters farther than the thrombus extends. Excision of the outer sinus-wall ensures free drainage. When it becomes evident that the septic degeneration in the transverse sinus has not been caused by occlusion by a solid thrombus, Jansen thinks that ligation of the jugular is indicated without further investigation of the sinus. This is to be followed by ligation of the facial vein. Of 25 cases of thrombosis of the transverse sinus recently operated upon by Jansen, 11 were cured—1 after simple emptying of a perisinuous abscess, 8 after opening the thrombosed sinus, and 2 with simultaneous ligation of the jugular. In 5 cases of opening the sinus and in 4 cases with ligation of the jugular death occurred.

Brieger[1] has suggested puncturing the cerebrospinal space in order to decide whether, in addition to a brain-abscess, there is also present a complicating meningitis. The result is sometimes negative, though meningitis be present. However, even in such cases Brieger concludes the surgeon may earlier decide to operate.

Lichtheim[2] and Fürbringer[3] have employed with great success as a means of diagnosis in suspected meningitis **Quincke's method of puncture of the subarachnoid space.** The puncture is made in the median line at the level of the spinous process of one of the lumbar vertebræ. The fluid and fibrinous coagula are then examined for bacilli.

Meier[4] calls attention to the **passage of suppuration of the middle ear to the brain by way of the carotid canal,** as already recorded by Körner and others. Inflammations of the brain thus excited do not differ from other forms.

OTITIC SINUS-PHLEBITIS.

Pitts,[1] Nash,[2] Lockwood,[3] Lucas,[4] Moullin,[5] Jansen,[6] Turner,[7] Barling,[8] and Böke[9] report cases of otitic sinus-phlebitis. J. Orne Green[10] reports 3 successful cases of early exploration of the lateral sinus in cases of suspected sinus-phlebitis, in which the early and certain diagnosis of phlebitis of the lateral sinus from symptoms alone is in all cases difficult, and in most cases impossible. As the mastoid inner cortex is usually the starting-point of the phlebitis, as soon as the temperature rises suddenly and high in cases of suspected sinus-phlebitis Green proceeds at once to trephine the mastoid and explore the sinus. In all of the cases reported by Green[11] the presence of a clot was excluded by the exploration, and the removal of suppurating diploe doubtless prevented extensive phlebitis and thrombosis with their usually fatal results unless relieved by operation, which, unfortunately, is likely to be performed too late. Hence the wisdom of early exploration in suspected cases. Prompt relief can thus be given to the thrombosis if it has formed and before the thrombus has become infected. If thrombosis has not yet formed, the operation checks caries of the mastoid inner cortex and prevents further phlebitis of the sinus. Passow[12] reports a case of retention of pus in the antrum, perisinuous abscess, and sinus-thrombosis, in connection with very chronic purulent otitis media. The general symptoms were severe. A radical operation for exposure of the middle-ear cavities was insufficient for relief. Exposure and free opening of the sinus, with escape of pus and necrotic tissue therefrom, was followed speedily by relief of the brain-symptoms and ultimate cessation of the chronic purulent otorrhea. [No clue as to the cause of final infection.] Otogenous pyemia may be confounded with typhoid fever, miliary tubercle, acute malignant endocarditis, and malaria, but the local symptoms and history of ear-disease will establish the differential diagnosis, according to Hessler.[13] Septic sinus-phlebitis, from acute or subacute purulent otitis media, seems to occur at times, and to get well without the detection of pus in the mastoid antrum and cells, and without any surgical interference in the sinus or jugular vein, as in a case reported by Eskridge.[14] [The path of septic infection in such cases must be directly from the middle ear to the sinus by capillary veins.] It is worthy of note that septic phlebitis in the lateral sinus often occurs in connection with acute otitis media, as in 3 cases reported by Voss.[15] Delay in operating is dangerous, but death may ensue even when an operation is performed promptly upon the sinus before grave symptoms arise, as in 1 of

the 5 cases reported by Voss.[1] In these cases a profound osteomyelitis sets in. Of 5 cases operated upon by Voss, 2 proved fatal, 1 occurring in chronic and 1 in acute purulent otitis media. Influenza-otitis is sometimes followed by sinus-thrombosis, as shown in a case reported by Haug.[2] Recovery ensued in this instance after opening the sinus and freeing it from the thrombus. Severe meningeal symptoms and the optic neuritis observed in this case led to the diagnosis and the logical operation. Hessler[3] says that the treatment most satisfactory to both surgeon and patient in cases of sinus-phlebitis and pyemia of otitic origin is the "prophylactic." The first step is a thorough paracentesis of the membrana. The perforation must be maintained so as to permit free spontaneous drainage from the drum-cavity. If drainage in this way is not sufficient, a second channel must be made for its escape through the mastoid. All forms of inflation must be avoided, as well as syringings, moppings, etc. So-called "antiseptic treatments" are not as safe as they were once thought to be, or they have been shown to be "septic."[4]

If pyemia continue in spite of the antiphlogistic and prophylactic treatment as just given, and the pyemia is found to be due to osteophlebitis in the middle-ear cavities, all bone thus diseased must be removed, no matter how deep it may extend. If a subdural abscess is suspected to lie on the inner surface of the petrous bone, the outer surfaces of this bone must be chiselled away, though it appear healthy, the dura exposed, and the abscess evacuated. If sinus-thrombosis is suspected, the only sure way to find out the truth is "exploratory puncture of the sinus."[5] "Even the presence of a simple thrombus in the lateral sinus does not demand complete evacuation so long as the clot shows no signs of purulent degeneration." . . . . "Spontaneous cure of simple sinus-thrombosis in otogenous pyemia has been observed, though it is rare and cannot be in any way foretold." . . . . "If in otogenous pyemia carious defect in the bone of the transverse sulcus is found, this opening must be enlarged, the purulent thrombus removed, and double ligation and section of the jugular in the neck must be performed, in order to wash out the sinus and prevent the escape of thrombi into the general circulation." Hessler also warns against hasty operations on the sinus and jugular as follows: "If in cases of middle-ear suppuration, with chills and pyemic fluctuations in temperature, in which puncture of the lateral sinus and ligation of the jugular have demonstrated the circulation in them to be free, later on metastases occur, we must admit the possibility that the treatment introduced the further and more dangerous infection of the blood."[6] Eulenstein[7] reports a successful ligation and exsection of the internal jugular in a case of septic thrombosis of that vein.

Otitic Cerebral Abscess.—It is worthy of note that in this disease the wider pupil is observed upon the side corresponding to the unaffected half of the brain, as seen in 2 cases reported by Zeller.[8]

[1] Arch. f. Ohrenh., Sept., 1895. [2] Ibid., May, 1896.
[3] Die otogene Pyämie, Jena, 1896, Gustav Fischer, p. 500. [4] Op. cit., p. 449.
[5] Op. cit., p. 451. [6] Op. cit., p. 466. [7] Zeit. f. Ohrenh., June, 1896.
[8] Arch. f. Ohrenh., Dec., 1895.

According to Oppenheim,[1] aphasia occurring in otitic abscess of the left temporal lobe is due to a lesion of the *sensory speech-center*—an interruption in the paths connecting this part with other cortical areas. True *motor* aphasia from otitic abscess of the left temporal lobe has not yet been described, according to Oppenheim.

Hemianopsia in Otitic Cerebral Abscess.—Lannois and Jaboulay[2] observed sudden vertigo, titubation, intense headache, right hemiparesis, aphasia of conductibility without verbal deafness, and lateral homonymous hemianopsia on the right side, with conservation of pupillary reflex, in a man the subject of chronic otorrhea for 25 years. The diagnosis of the presence of an otitic abscess in the occipital lobe was confirmed by operation and postmortem examination. According to these authors, the aphasia of otitic cerebral abscesses is oftener an aphasia of conductibility than a pure motor aphasia.

Bicameral Abscess in the Temporal Lobe.—Kümmel[3] observed the occurrence of a bicameral abscess in the temporal lobe, following acute otitis media, in a child of 3, notwithstanding repeated opening of the mastoid cavity. One abscess-cavity was emptied, but death ensued 6 months after the onset of the acute otitis. [It would be highly instructive if we knew what had been done for the acute otitis before mastoid symptoms set in. We can see no reason in the history of the case, as given, for a mastoid, and finally an intracranial lesion, excepting in early secondary infection of the middle ear by improper treatment.] Treitel[4] in an article on multiple otitic abscesses of the brain states that, according to Körner, cerebral abscesses are multiple in about 16%, and, according to Schwartze, in about 17%, of such otitic lesions of the brain. Treitel gives an account of multiple otitic abscesses of the brain in a man of 22. One abscess was in the temporal, the other in the occipital lobe.

Extradural Abscess.—Kümmel[5] reports the occurrence of an extradural abscess following recurrent acute otitis media, in which the posterior cranial fossa was exposed and recovery ensued.

Optic Neuritis.—Burnett[6] calls attention to the fact that abscess of the cerebrum is generally too rapid in its course to occasion even unilateral optic neuritis, much less double optic neuritis. Pooley[7] maintains that optic neuritis is never present as long as the purulent disease is limited to the ear. It is noticed in otitic meningitis, sinus-thrombosis, and brain-abscess.

OTITIC CEREBELLAR ABSCESS.

Bacon[8] reports a case of cerebellar abscess in a man of 33, the result of chronic suppuration in the middle ear. Luc and Dundas Grant[9] have reported cases of cerebellar abscess in which the symptoms were very slight—no fever, no motor disturbances—and in which death occurred very suddenly and unex-

[9] Brit. Med. Jour., Nov. 16, 1895.

pectedly. [It is to be regretted that we are not informed as to the condition of the eye-ground in these cases, as double optic neuritis is very often the only pathognomonic symptom of lesion in the posterior cranial fossæ.] Burnett[1] calls attention to the fact that double optic neuritis is likely to be present in cerebellar tumors and otitic cerebellar abscesses, because such lesions readily interfere with the circulation of the cavernous sinuses and ophthalmic veins. In fact, double optic neuritis is the only positive symptom of the presence of an otitic cerebellar abscess, as shown by Hansberg and Risler in 1894 and 1895 (see the *Year-Book* for 1896, p. 866). In all cases, however, the symptoms of cerebellar abscess "depend upon the level of the pressure" (Macewen). Woods[2] also reports a case of cerebellar abscess from chronic purulent otitis media in a girl of 20, in which the mastoid was opened, the middle ear cleaned out, the thrombosed lateral sinus laid bare, and the cerebellar abscess evacuated. The internal jugular was ligatured in the neck and the clot removed, but the patient died in 15 days from asthenia. Heiman[3] reports another case (his seventh) of otitic cerebellar abscess, occurring in a man affected with chronic otorrhea in the right ear. The symptoms were slow pulse, temperature 37° C. (98.6° F.), intense headache, chiefly in the right occipital region, vertigo, disturbed coordination of head, which rotated backward and forward and from right to left, continuous vomitings, constipation, difficulty of deglutition, retention of urine, speech slow and difficult, inequality of the pupils, right facial paralysis and vasomotor disturbances on the left side, augmentation of tendon-reflexes, apathy, somnolence, and general debility. Contrary to Heiman's advice, the abscess was sought in the temporosphenoidal lobe, instead of in the cerebellum. Though no pus was found, the patient grew markedly better for a short period: then he grew worse. Antisyphilitic treatment was then tried in vain, the mastoid and attic trepanned, and finally the region of the right lobe of the cerebellum was explored, but no pus was discovered there by the operation. The postmortem examination revealed an abscess in the right lobe and in the processus vermiformis of the cerebellum. The disease had existed 3 years in all; the abscess had been developing probably $2\frac{1}{2}$ years, in Heiman's opinion.

The eye-grounds may remain normal even in fatal cases of otitic cerebellar abscess, as observed in a boy of 13 by Woodward.[4]

Rupture of Brain-abscess into the Posterior Cranial Fossa.—Zeller[5] records 2 cases.

Gliosarcoma of the Quadrigeminal Body.—Passow[6] observed in connection with chronic purulent otitis media what he mistook for symptoms of cerebral abscess, but which proved to be gliosarcoma of the quadrigeminal body. Schwartze[7] too mistook the symptoms of a brain-tumor for those of an otitic cerebral abscess. [The slow onset of the symptoms—headache, vomiting,

[7] Arch. f. Ohrenh., Dec., 1895.

low temperature, choked disks on both sides, and a wider pupil on the side corresponding to the diseased ear—should have induced him to have diagnosed a cerebellar rather than a cerebral lesion.]

Otitic Meningitis.—Swain[1] reports a case of basilar meningitis following otitis media, in which invasion of the skull took place through the cochlea and internal auditory meatus. Dench[2] reports a case of otitic leptomeningitis in which recovery followed an operation. Beach[3] calls attention to the fact that a chronic purulency in the ear or nose may be a source of infection of the brain-cavity in fractures of the skull if they communicate in any way with the nasal cavities or temporal bone and middle ear. He claims that many cases might recover had they not been affected with chronic purulent ear-disease before the fracture of the skull occurred.

DISEASES OF THE NOSE AND LARYNX.

By E. FLETCHER INGALS, M. D., and HENRY G. OHLS, M. D.,
of Chicago.

The Principal Features of the Year's Work.—The presence of microorganisms and the use of antiseptics in the nares and vestibule have been during the year the subject of exhaustive researches on the part of Thomson and Hewlett. Electrolysis in hypertrophic rhinitis was the subject of an able article by Scheppegrell. Casselberry described the same method as applied to the reduction of septal spurs. Remarkable results in the treatment of ozena by inhalation of oxygen were recorded by Stoker. For nasal hemorrhage Vansant and Gillette successfully used hydrogen dioxid; to relieve headache from various causes Capp insufflated sodium chlorid into nares. The relations of intranasal disease to deafness and to melancholia were treated respectively by John A. Thompson and Bosworth, with relation of striking cases. In an extended discussion of the etiology of nasal polypi by the British Laryngological Society the necrosing-ethmoiditis theory of Woakes received its coup de grace, an observation by Williams accounting for the bare-bone sensation sometimes noted. The hope that the toxin of erysipelas would prove a specific for sarcoma is not encouraged by the unfavorable experience of Pierce and Lederman. Berens offers an extemporaneous nasal splint made of cork. Transillumination of the antrum is rendered almost as simple as inspection of the nares by the method suggested by Ohls. Diseases of the accessory sinuses have been extensively discussed in medical societies, and have given rise to a vast amount of literature. More extensive use of preparations of the thyroid and thymus glands in the treatment of goiter and Graves' disease has served to define the limitations of these remedies. For examination of the larynx Kirstein's autoscope is available in certain cases. Interesting experiments in the examination of the larynx and trachea by the Röntgen rays in connection with the cryptoscope have been reported. The use of antitoxin has reached the statistic stage, and the reports continue favorable, though Ingals points out many sources of error in the statistics submitted. Intubation for diphtheria was ably treated by Strong, and Wetherla devised an ingenious electromagnetic tube-extractor. As usual, tuberculosis of the larynx occupies an important place, and many important articles have appeared both on surgical and local medical treatment. Laryngeal neuroses and affections of the voice have received due attention. Hodgkinson has studied the physiology of the vocal cords. Muir described a novel method of medication of the bronchi.

THE NOSE.

Anatomy of the Nasal Mucous Membrane.—Wright[1] describes the vascular arrangement in sheep, which is frequently similar in man. The muscle-walled sinuses lie between the arteries and periosteum, so that the swelling of the arteries diminishes the size of veins. In chronic rhinitis the veins are thickened by growth of nonelastic fibrous tissue. In hypertrophic rhinitis the walls are dilated and paretic. Atrophy consists in substitution of fibrous for muscle-tissue and absorption of the former. Turgescence of capillaries surrounding orifices of glands closes the latter and causes the dry stage of acute coryza.

Anatomy of the Nose in the Embryo.—Killian,[2] from the examination of 239 embryos from the third to the ninth month, noted from 8 to 10 anteroposterior folds of mucous membrane on the vomer. These appear in the 3d or 4th month, and persist to the 9th, or in posterior portions to adult life in about one-third of the cases. Their function is to warm and moisten the air. The innervation is by the nasopalatine nerve. He believes persistence in adults dependent on climate and mode of life.

Anesthesia.—Newcomb recommends ethyl bromid for short operations. If long continued, it causes hypersecretion and muscular contraction. For a local anesthetic he recommends antipyrin 10, cocain 1, water 10 parts. Antipyrin, 50% solution, injected in laryngitis relieves pain for 12 hours. For the pharynx guaiacol, 5% in olive oil, applied on a swab with friction, gives longer anesthesia than cocain. Arslan used ethyl bromid 252 times without the least disagreeable symptom. Under 15 years of age 10 g. suffice; above that age the dose may be doubled. He collected 4161 cases, with few unsuccessful results and no deaths. Silk[3] said that for slight operations, like breaking up an adenoid with the finger-nail, an anesthetic may be given with the patient sitting up or semirecumbent. Nitrous-oxid gas with a whiff of ether is enough even for operations on spurs of the septum. When forceps or curet is used he gives A. C. E. mixture or a little chloroform for young children, finishing with Junker's bottle with the tube in mouth. Cocain he finds uncertain and treacherous, and is inclined to attribute favorable effects to idiosyncrasy or hypnotic suggestion. [Careful operations on the septum require from 10 to 20 minutes, or even more. It appears very difficult to secure the proper anesthesia, as recommended by Silk. Cocain has not proved treacherous or uncertain in our experience.]

Antiseptics and Intranasal Applications.—Thomson[4] draws the following conclusions: 1. The interior of the normal nasal cavity being practically aseptic, there is no need to render it more sterile than it is; 2. The presence of any foreign body in the nose tends to produce a flow of watery, and therefore weakened, mucus. The ciliated epithelium rapidly expels any solid particles coming in contact with it. Hence it is advisable to dispense

[1] Am. Jour. Med. Sci., May, 1895.
[2] Arch. f. Laryn. u. Rhin., 21, No. 2, p. 234.
[3] Practitioner, Oct., 1895.
[4] Practitioner, Dec., 1895.

with intranasal medication unless there is some indication outweighing these considerations; 3. It is more important to cleanse away any purulent accumulations in the nasal cavities by alkaline nonirritating liquids than to attempt the employment of strong antiseptic solutions; 4. It is important to disinfect any instrument or finger introduced into the nasal cavity or nasopharynx. For this purpose there is a choice of liquids, several of which will prove more easy and reliable than the adoption of an entirely aseptic method. If instruments are well scrubbed with a 5% solution of phenol immediately after use, and kept in a clean glass cupboard, it will be quite sufficient to immerse them for a short time in the same liquid before a subsequent operation.

Surgical Principles in Nasal Diseases.—Bischof[1] advises as follows: In using the douche avoid high pressure and long application; there should be no swallowing or coughing; incline the head forward; give through a narrower nostril; clear the nares with one nostril open; the nozzle of the douche should fit the nostril loosely; wear cotton-wool in the nostril after the douche; the solutions should be weak; chromic acid should always be followed by an alkaline wash; the galvanocautery should be followed by ointments and daily breaking down of the adhesions; sterilize all instruments and irrigate the nares with antiseptics after the operation. [Daily breaking down of adhesions is unnecessary except in very rare cases. Usually it is sufficient to see the patient once only, the fourth or fifth day after the cauterization.] Simpson[2] emphasizes conservatism. He notes the liability of inducing atrophy by too extensive operations.

Cocain-habit.—Bosworth[3] reported that he had never met with a case of cocain-habit that seemed much more serious than the chewing-gum habit. As a rule, the habit is associated with rum or morphin. [In this his experience is very different from that of most other laryngologists. The editors have seen not less than 40 persons much injured by the habit, and several (probably 10, who were physical and moral wrecks from the cocain-habit, formed usually from taking various so-called catarrh powders, but not infrequently from continuing the treatment ordered by some physician.] Sharp[4] related 2 cases of cocain-habit in which from 3 to 5 gr. were taken daily by the nares. In one case, a male of 27, sexual desire and ability were entirely absent. In the other, a man of 32, the first use of the drug in the morning habitually had a laxative effect.

To Heat Cautery-irons.—Scheppegrell[5] describes a method of heating large cautery-irons (Fig. 154). A 2-quart glass jar is three-quarters filled with a solution of borax, 1 part; sodium carbonate, 10 parts; water, to make the specific gravity 1030. A plate of lead 1 in. wide is coiled around the bottom of the jar, and to this is soldered the positive wire of the Edison current of 230 volts and 15 ampères. The negative wire passes across the top

[1] Quoted in Am. Med.-Surg. Bull., Feb. 8, 1896.
[2] N. Y. Med. Jour., Sept. 14, 1895.
[3] Am. Med.-Surg. Bull., Mar. 7, 1896.
[4] Boston M. and S. Jour., Jan. 2, 1896.
[5] Med. News, Aug. 10, 1896.

of the jar. Placing the neck of cautery on the negative wire and immersing the point in the fluid, the iron instantly becomes red hot, and in 3 seconds white hot. He used this method to control a hemorrhage after tonsillotomy which the Paquelin cautery failed to control. Sleicher[1] has devised a rheostat attached to the handle of a galvanocaustic snare to diminish the current while tightening the loop. He also uses guiding rings instead of a tube to avoid friction.

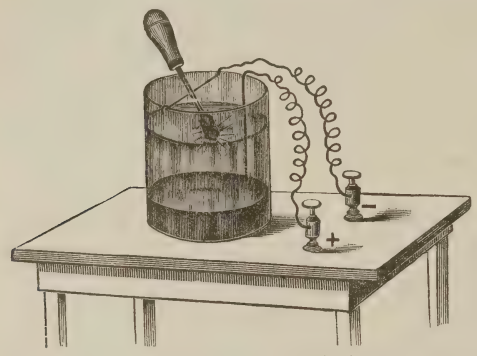

FIG. 154.—Apparatus for the heating of cautery-irons (Med. News, Aug. 10, 1895).

Damp Air and Diseases of the Air-passages.—Roe[2] distinguishes between dampness and humidity. Sudden checking of insensible perspiration causes the sensation of a cold, the common source of all catarrhal conditions of the bronchial tract. Mucous tissue subjected to a damp atmosphere becomes turgescent, hence the prevalence of catarrhal affections in the region of the Great Lakes. Sleeping near open windows accounts for many colds from exposure to damp night air. Bowditch years ago showed that consumption in New England was associated with districts and houses that were damp.

Bacteria in the Nares.—Thomson and Hewlett[3] state that the hourly inspired air amounts to about 500 liters and contains at a low average 1500 germs. The authors review the literature of the subject and describe their own experiences: 1. In all bacterioscopic investigations of the nasal fossæ, in all researches as to the action of nasal mucus, etc., a clear distinction must be made between the vestibule of the nose and the proper mucous cavity. The former is lined with skin and is furnished with hairs and sweat and sebaceous glands. It is no part of the proper nasal cavity, and only leads to it; 2. Neglect of this distinction may account for the discrepancy in previous observations on the subject; contamination from the lining of the vestibule is difficult to avoid even when this source of error has been realized; 3. In the dust and crust of mucus and debris deposited among the vibrissæ of healthy subjects microorganisms are never absent, and are rarely scanty in number; as a rule, they are abundant; 4. On the Schneiderian membrane the reverse is the case. The authors do not assert that germs are completely absent; obviously some must occasionally occur, but under normal conditions they are never plentiful; they are rarely even numerous, and in more than 80% of their observations no organisms whatever were found and the mucus was completely sterile.

Cretinism and its Effect on the Nasal Chambers.—Allen[4] describes

[1] Quoted in Jour. of Laryn., Oct., 1895.
[2] N. Y. Med. Jour., Nov. 23, 1895.
[3] Med.-Chir. Trans., 78, quoted in Am. Med.-Surg. Bull., Sept. 1, 1895.
[4] N. Y. Med. Jour., Feb. 2, 1895.

2 skulls showing cretinoid degeneration. In one the nose was prominent, the facial bones stunted, and the hard palate small. In the other the nasal bones were vertical, not projecting beyond the nasal processes of the maxillæ. The inferior turbinated bones of both were attached higher up, and were apparently of great size, probably owing to extreme shortening of the face, so that a compensatory growth occurred in these bones in the vertical direction. The floor of the nose was depressed below the level of the anterior aperture.

Hypertrophic Rhinitis; Bipolar Electrolysis.—From an experience of over 100 cases with the bipolar method of electrolyzation Scheppegrell[1] draws the following conclusions: As compared to the monopolar method, it is more rapid in its application, less painful, and more definite in action. As compared to other methods, it is more conservative, and it effects the destruction of the tissues without destroying the mucous membrane and its glandular elements. It has not the disagreeable after-pain following the application of chromic acid; being a submucous operation, the reaction following it is very slight. He has never seen a synechia formed in the nostril due to the effect of electrolyzation. As the operation is not performed as rapidly as by means of the galvanocautery, it is not so practicable in cases of young children or very nervous patients. The physical conformation of some nostrils renders it difficult to properly insert the electrolytic needles, and in these cases some other method must be adopted.

Rhinitis.—Fermi and Bretschneider[2] have made careful clinical and bacteriologic researches upon acute rhinitis. Their paper is probably the most elaborate yet written on the subject of the flora of the nasal region. They come to the following conclusions: 1. Simple coryza is not a germ-disease; 2. Many coryzas are due to the irritant action upon the nasal mucosa of exciting agents partly physical and mechanic, partly chemic—agents which attack the mucosa either from the external surface (trauma, polypus, chemical fumes, etc.) or from within (the ingestion of the iodids, the infectious diseases, etc.); 3. Colds are really due to functional, trophic, vasomotor disturbance of the mucosa of a nervous kind. They are due not to the action of mere cold as such, but to sudden and severe changes of temperature combined with a high hygrometric state, during which slight variations of temperature are more keenly felt; 4. Hay fever, so called, occurs in persons in whom trophic innervation of the nasal mucosa is permanently altered in consequence of a persistent functional alteration of the nervous system, either congenital or acquired. This may arise not merely from the ordinary physical factors, mechanic or chemic, but also in a reflex manner from excitants of general or special sensibility.

Dry Treatment.—Siebenman[3] says rhinitis is the cause of recurring epistaxis and nonsyphilitic perforation of the septum. He advises ointments,

[1] La Rev. Internat. de Laryn.; ref. Ann. of Ophth. and Otol., St. Louis, Apr., 1896.
[2] Arch. ital. di Otol., iv.,1895; ref. Am. Med.-Surg. Bull., May 2, 1896.
[3] Quoted in Am. Med.-Surg. Bull., Jan., 1896.

avoiding picking at crusts, saline baths, and tonics. For the ulcers that result he applies powdered potassium permanganate applied on a moistened cotton wound-probe.

Nasal Diphtheria, Primary.—Eeman[1] reported several cases of primary nasal diphtheria not extending to other parts. The general health was not affected. The symptoms were coryza with nasal obstruction and sometimes epistaxis. Virulent Löffler's bacilli were present. One case treated with Roux's serum was much shortened.

Etiology of Membranous Rhinitis.—Ravenel[2] reviews the literature of 77 cases, in 41 of which bacteriologic examinations were made, showing the Klebs-Löffler bacillus in 33. He notes that while the disease is usually mild in type, it is really a form of nasal diphtheria, and cases should be isolated. He reports finding the Klebs-Löffler bacillus in 10 out of 14 cases examined personally. Felsenthal[3] saw 2 cases in Berlin: 1 showed the Löffler bacillus of weakened virulence, the other none. Katz recently reported a case of typical pharyngeal diphtheria contracted from a relative with fibrinous rhinitis. Kyle[4] divides membranous inflammation into—Specific, due to specific bacteria; Nonspecific, including the fibrinoplastic variety. The symptoms are those of acute rhinitis with nasal stenosis and some constitutional depression. He describes 2 cases in children. The membrane was firmly adherent, and hemorrhage followed the removal. Culture showed staphylococcus pyogenes aureus and albus. He believes that while the disease is nondiphtheric, it is best to treat all cases of membranous inflammation of the upper air-passages as if they were true diptheria.

Etiology of Ozena.—Abel[5] says fetor is an inconstant and secondary symptom. The process may extend to the nasopharynx or begin there, and it may spread to the sinus, middle ear, larynx, and trachea. It is infectious. The cause is the bacillus mucosis ozenæ, resembling closely the pneumobacillus, but distinguishable from it. The fetid decomposition of the crusts is caused by other microorganisms. [Clinical experience does not corroborate the view of this affection being infectious.]

Bacteriology of Ozena.—Fage[6] reviews the subject and describes the coccus-like bacilli arranged in pairs surrounded by a capsule and occasionally coupled in small chains. They stain with anilin and are decolorized by Gram solution.

Treatment of Ozena.—Wright[7] criticises as inefficient the treatment by cauterization advocated by Rethi,[8] who proposed to cauterize by escharotics or the hot platinum knife, though he said the patients would get well of themselves in time. Stoker[9] described 2 cases of ozena cured by inhalations of oxygen through the nose, without other treatment. One was syphilitic ozena

[9] Jour. Laryn., Mar., 1895.

of 5 years' duration, in which 1 month's treatment by inhaling the oxygen every alternate hour during the day caused complete disappearance of the odor. In another case of 2 years' standing associated with chlorosis, 3 days' treatment stopped the odor. In a case of suppurative middle-ear disease lasting 7 years, 9 weeks' treatment by inhalation 4 hours daily stopped the discharge, pain, and odor, and improved the hearing greatly.

Coryza.—Lermoyez[1] classified the predisposing causes: 1. Defective hygiene in diet and occupation; 2. Nasal lesions; 3. Visceral, gastrointestinal, genital, and circulatory lesions; 4. Systemic diseases and diathesis.

Schnee[2] advocates the principle established by Goltz—viz. that light shocks for a short time cause contraction of the blood-vessels; stronger and more prolonged shocks cause dilatation. Owing to the distribution of the nasociliary nerves the circulation of membranes covering the septum and turbinated bones is modified by blows delivered with the rubber hammer to the region of the inner canthus, the inner half of the brow, and the whole surface of the nose. For acute coryzas the blows should be light—for chronic conditions stronger, the shocks to be followed by friction of the nose. [This would appear to be a method in which the treatment would have to be prolonged for such a time that it would be difficult to determine whether the results were not entirely due to the efforts of nature.] Cohen[3] found that tincture of belladonna, 5 minims, added to the 10-gr. dose of potassium iodid, checked the coryza.

Winsche[4] claims that 10 gr. of chloroform holding in solution from 5 to 10 mgm. of menthol, will arrest a coryza in its early stages, and that this remedy is an excellent prophylactic against influenza. From 4 to 6 drops of the solution are poured into the hollow of one's hands; the two palms then are rubbed together, and the vapor is inhaled through the nose and mouth. Sometimes the coryza is arrested after the first inhalation, but it is recommended to repeat the inhalation once or twice during the day. [It will be remembered that it was Dr. Solis-Cohen who in 1872 first recommended the use of chloroform in acute coryza. Chloroform alone, camphor, ammonium carbonate, iodin, and other volatile substances will produce similar results.]

Coryza in Children.—Woodruff[5] states that the nasal mucus kills the germs of anthrax and of all respiratory diseases. Nasal stenosis causes hyperemia of all the respiratory mucous membrane, and in children pavor nocturnus, enuresis, deficient development of chest, dulness of special senses and mental hebetude, greater susceptibility to zymotic diseases and scrofula, even scoliotic deformity of the spine. Ziem produced the latter in kittens by suturing one nostril.

Hay Fever.—Abercrombie[6] found zinc valerianate pills, 3 gr. each, taken 3 times a day after eating, preventive and apparently curative in 1 case of hay

[1] L'Union méd., Mar. 16, 1895. [2] Rev. de Laryn., Nov. 1, 1895.
[3] Lancet, No. 3750.
[4] Comment by Ann. of Ophth. and Otol., Apr., 1896, from Therap. Monatsh., Nov. 9, 1895.
[5] Med. Rec., N. Y., Apr. 25, 1896, quoted from monograph by Finck of Hamburg.
[6] Brit. Med. Jour., Apr. 15, 1896.

fever, the patient being distinctly neurotic. The pills were taken for a month before and during the attack, with the result of almost entirely preventing the attack. The second year the same remedy gave relief throughout the season, with the exception of 1 hour, when some of the symptoms were felt. In a paper on hay fever Strangways[1] urges the necessity of removing all diseased conditions in the nares, and claims that if we do so the frequent use of a nasal wash consisting of 2 minims of acetic acid, 1½ gr. of resorcin, and 4 gr. of salt to the ounce of water will, with the free administration of muriatic acid internally, abort and cure an attack. Smith[2] recommends the following ointment, introduced into the nares, as giving almost instant relief:

℞.	Mentholis,	gr. xx;
	Olei amygdal. dulcis,	ʒij;
	Acidi carbolici,	♏x;
	Cocain. hydrochlorat.,	gr. vj;
	Unguent. zinci oxidi,	ʒss.—M.

Influenza.—Delavan[3] disapproves of operation on the nose during an epidemic of influenza, as operations usually cause a relapse with marked depression. The wound invites infection. Hay fever he considers also a contraindication for operation.

Treatment of Epistaxis.—Gillette[4] says for several years he has used a teaspoonful of hydrogen dioxid, injected into the nares, for hemorrhage, with immediate relief. During operations inject the remedy, have the patient blow the nose, and the field is again clear. Woolen in a discussion of Dr. Vansant's paper suggested insufflating dermatol as an efficient hemostatic and antiseptic. Vansant[5] reviewed the causes of epistaxis in general, and related 37 cases, of which 28 were due to slight deformity of the anterior portion of the septum with ulceration of the projecting or convex side; 3 were due to deviation of the septum with ulceration on the depressed or concave side; 2 were due to ulceration associated with atrophic rhinitis; 1 to a vicarious menstruation; 3 occurred in typhoid fever. He recommends removal of spurs and refracture of deviated septa. To stop bleeding use hydrogen dioxid pure, or alum 30 gr. to the ounce of water, or cocain 4%, followed by antipyrin from 3 to 6%. To prevent recurrence avoid picking, use warm douches and oils, with silver nitrate or balsam tolu applied to the ulcer. [We think the words "due to" in this paragraph should be replaced by "associated with." We have not seen cases in which the deflection seemed an etiologic factor.]

Trigeminal Neuralgia and Nasal Diseases.—Collier[6] reported 2 cases of severe and persistent facial neuralgia, which had resisted all treatment, cured by removal of diseased middle turbinated tissue. In 1 case the neural-

[4] Ibid.; N. Am. Pract., Jan., 1896.
[5] Jour. of Am. Med. Assoc., Nov. 23, 1895.
[6] Lancet, 1895, vol. ii. No. 3757.

gia had existed 4 years, and in the other the troublesome symptoms had been present off and on for 12 years.

Anosmia and Ageusia.—Schirman's[1] patient was a foundryman, aged 29, who lost the sense of smell and taste following an injury to the brain in the right temporooccipital region, without any disturbance of common sensation or motion. Irritating and caustic vapors would cause sneezing, but loss of smell was absolute. The patient could distinguish the taste of certain substances in dilute solution, but stronger solutions were tasteless. After excluding injury to the nerve-trunks the author concludes that the trauma was confined to the cortical centers.

Parosmia.—Tilley[2] describes 3 cases in which the nasal cavities and mucous membranes were normal. A man of 38 complained of a strong smell of ammonia following influenza. Another complained of the smell of tallow candles. Intranasal spray of liquor strychnia, 10 minims to the dram, cured the first, but failed in the second case. A woman 46 years of age complained of a foul smell—a case of climacteric neurosis that improved under general treatment.

Deafness from Intranasal Disease.—Thompson quotes Swinburne,[3] who found 95% of deafness due to middle-ear disease caused by primary lesion of the nose or nasopharynx. He then described 3 cases of total deafness associated with nasal obstruction, all greatly improved by removal of spurs from the septum and cauterization of hypertrophied turbinated bodies. One patient was alarmed after the operation at hearing the ticking of a clock for the first time.

Melancholia and Intranasal Disease.—Bosworth[4] reports a case of melancholia associated with right nasal occlusion from deviation of the septum and enlarged left middle turbinated bone, with myxomatous degeneration and ethmoiditis. The removal of all obstructions relieved the melancholia. The patient had previously undergone operations for varicocele, stricture, and hemorrhoids; he had submitted to castration, circumcision, ligation of the internal pudic artery, cautery to spine, seton in the neck, tenotomy of the eye-muscles, and enucleation of a healthy eye. The author attributes the melancholia to some organic change at the base of the brain, due to the ethmoid disease with pressure and circulatory disturbances.

Insufflations of Sodium Chlorid for Nasal Pain.—Capp[5] gives his experience with this remedy, first used by Mr. G. Leslie.[6] In 5 adults with faceache from decayed teeth pain was relieved at once by the insufflation of from 2 to 4 gr. of finely-ground salt. Many cases of headache from various causes yielded immediately to this remedy. A physician with headache and painful eyes, due to reading and work with the microscope, was promptly relieved. Insufflation was attended by great suffusion of eyes and nose.

[6] Edinb. Med. Jour., Jan., 1895.

Etiology of Polypi.—In a general discussion Guye[1] said we must ascribe to the mucous membrane a peculiar predisposition which makes it produce nasal polypi as a reaction to noxious influences of different natures. Luc controverted the necrosing-ethmoiditis theory of Woakes by presenting preparations in which the underlying bone was normal, and noted the great similarity between myxomatous degeneration and simple edema of the membrane. He accounts for the usual location by the presence of folds in the membranes about the hiatus. Zuckerkandl classified polypi as inflammatory hypertrophies due to chronic irritation of the nasal membrane. He never found necrosis or carious bone, but often hypertrophy. McBride concludes that gravity is an important factor, and in some cases inflammatory changes alone may be the starting-point of the disease. Lake considers mucous polypi an outcome of hypertrophic rhinitis, with which tissue it is histologically identical. In examining a large number he had never seen a myxoma or an edematous fibroma. Williams, noting the observations of Zuckerkandl of spiculæ of bone sometimes projecting into polypi from their attachment through the periosteum, believes that they will account for the so-called rough or bare bone said to have been detected in certain cases. He believed Hopman's theory of polypoid formation from vascular obstruction. De Roaldes attributes the rarity of polypi among the negroes to more roomy nares with better drainage, and their diminished liability to acute rhinitis. Syphilitic necrosis is common in them, but is never productive of polypi. Roy[2] reported a congenital polyp in a girl persisting to the age of 14.

Fibroma of Myxomatous Variety.—Mulford[3] describes a large 3-lobed fibroma attached to the posterior end of the middle turbinated bone, removed with a snare in a curved cannula passed through the oropharynx.

Polypi and Tachycardia.—Watson[4] describes the case of a male of 35 with polypi in both nares and a pulse of 120, which became normal after removal of the polypi.

Papilloma or Papillary Fibroma of the Septum.—Wright[5] gives a description of a growth attached to the upper part of the cartilaginous septum near the columella (the point of friction in inspiration). The pedicle was small and the growth pedunculated and covered with columnar epithelium, except where friction caused the cells to approximate the squamous type. Baber[6] reported a papilloma removed from the floor of the nares and lower part of the septum. De Santi referred to a case shown by him the year before. All of these were attached near the entrance to the nose.

Polypi and Sarcoma.—Wright[7] reviews a case of mucous polypus which after many recurrences ended in a vast encephaloid sarcoma.[8] Wright thinks that the parts removed were only edematous tissue from inflammatory process set up by growth of sarcomatous elements developed in the tissue.

[8] As reported by Bonain in Rev. de Laryn.

Bleeding Tumor of the Nasal Septum.—Sendziak [1] contributes the notes of a case in which he removed with a hot snare in two sittings a sarcomatous cavernous angioma. The patient was a man of 34, who had had obstinate epistaxis for a year. The growth was attached to the posterior superior part of the cartilaginous septum—not in Kiesselbach's place. Freudenthal [2] reported a fibroma angioma in a woman of 22 (Fig. 155). On removal

FIG. 155.—Section of fibroangioma of nasal septum (× 600): *c, c*, capillary blood-vessels lined by large endothelia in transverse section; *l*, capillary blood-vessels, with partly-detached endothelia in longitudinal section; *s*, clusters of endothelia; *f, f*, delicate fibrous connective tissue (Ann. of Ophth. and Otol., July, 1895).

with the snare alarming hemorrhage occurred. The tumor was located in Kiesselbach's place. The stump required cauterization. The author thinks the vascular tumors are due to direct injury to that region not sufficient to break the vessels at once.

Toxin and Ligation of Carotids; Nasal Sarcoma.—Lederman [3] describes an exceedingly interesting case of sarcoma of the nares for which both the toxins were injected and the common carotids were ligated. The patient was a man of 26, with round-celled sarcoma filling the right naris and projecting from both choanæ behind. The toxins were injected, beginning with 2 minims, which produced violent reaction, with chill, fever, and severe pain in the head and back, with swelling of face. Three more injections of 1 minim each were made at intervals of a few days, but the headache became unendurable and the patient refused to continue the treatment. Dawbarn then ligated both external carotids at an interval of 2 days between the operations. Two months later the tumor had diminished so much that its attachment to the middle turbinated bone was visible, and the patient had gained 20 pounds in weight. The writer intends to remove the mass with the cold snare.

[1] Jour. of Laryn., Mar., 1896. [2] Quoted in Ann. of Ophth. and Otol., July, 1895.
[3] Med. Rec., Nov. 30, 1895.

Pierce[1] records 2 undoubted and complete failures in the use of the toxins of erysipelas and the bacillus prodigiosus for sarcoma. The quantity used varied from 2 to 10 minims, and was followed by a chill, with great prostration and a temperature of from 101° to 103°. In a case treated by others with the toxins he removed the growth on recurrence, and it proved to be a fibroma polyposum fungoides teleangiectoides.

Syphilis.—Seifert quotes 27 cases of chancre of the nose, mostly on the ala nasi, least often on the septum. He notes the early induration and obstruction. In 1 case there was intense frontal headache, in another there were swelling and elevated temperature. There was indolent swelling of the submaxillary, sublingual, and preauricular glands.

Nasal Tuberculosis.—Polyak[2] describes a case of primary tuberculosis of the septum without other lesions in a well-nourished woman of 49. The right naris was full of easily-bleeding granulation-like tissue, showing giant-cells and tubercle-bacilli.

The Nose in Phthisical Patients.—Clark[3] compared the conditions found in the nares of 100 phthisical patients with those found in 100 healthy subjects, with the following results: In the healthy the turbinated bones were practically normal in 56; in 43 they were atrophied; in none was there a ridge that was markedly obstructive. Of the phthisical cases, 73 were atrophied and 16 had considerable obstruction, while 32 had slight obstruction from spurs or ridges. [This corresponds with our observations in a large number of phthisical cases. The nares are usually abnormally large, and obstructions sufficient to interfere with respiration are very infrequent.]

Foreign Bodies in the Nose.—Harrell[4] reports a case of a man of 34 with a tooth projecting into the floor of the nose. He had had severe neuralgic pain and nasal discharge for 6 years. Vaae[5] relates the case of a woman of 35 with a supernumerary tooth in the floor of the nose.

Animal Parasites in the Nose.—Bond[6] describes a woman of 49 with sharp pain in the left frontal region and profuse watery discharge for 3 weeks. She was treated 6 weeks without effect, when 4 grubs came from the nares following the application of dilute Mandl's solution, 15 minims to the ounce. Some of the grubs developed into flies, and were identified by Chas. O. Waterhouse of the Natural History Museum as Piophila casei (Linnæus), the larvæ of which feed on cheese, bacon-fat, and animal matter generally.

Etiology of Stenosis of the Nares.—Collier[7] stated that only 110 patients out of 1050 examined at the Northwestern London Hospital had vertical septa and symmetrical nares. Obstruction is rare under 10 years of age, is seldom or never congenital, and is more common after puberty. Nine-tenths of civilized persons have some abnormality of the nose. The septum is a delicate partition for the support of mucous membrane. Temporary nasal

SAUNDERS'
AMERICAN TEXT-BOOKS

receive spontaneous and meritorious recognition, and

ARE PHENOMENALLY SUCCESSFUL.

PEPPER'S NEW "AMERICAN TEXT-BOOK OF PRACTICE."

From the NEW YORK MEDICAL JOURNAL

We reviewed the first volume of this work and said: "It is undoubtedly one of the best text-books on the practice of medicine which we possess." A consideration of the second and last volume leads us to modify that verdict and to say that the completed work is, in our opinion, the **best** of its kind it has ever been our fortune to see. It is complete, thorough, accurate, and clear. It is well written, well arranged, well printed, well illustrated, and well bound. It is a model of what the modern text-book should be.

"AN AMERICAN TEXT-BOOK OF GYNECOLOGY."

From the NEW YORK MEDICAL RECORD

As a text-book it is well up to the most advanced views of the day, and embodies all the essential points of advanced American gynecology. It is destined to make and to hold a place in gynecological literature which will be peculiarly its own.

"AN AMERICAN TEXT-BOOK OF SURGERY."

Extract from THE LONDON LANCET.

"If this text-book is a fair reflex of the present position of American Surgery, we must admit it is of a very high order of merit, and that English surgeons will have to look very carefully to their laurels if they are to preserve a position in the van of surgical practice."

"AN AMERICAN TEXT-BOOK OF DISEASES OF CHILDREN,"

Extract from AMERICAN JOURNAL OF MEDICAL SCIENCES.

"This is far and away the best text-book of children's diseases ever published in the English language, and is certainly the one which is best adapted to American readers. We congratulate the editor upon the result of his work, and heartily commend it to the attention of every student and practitioner."

"AN AMERICAN TEXT-BOOK OF OBSTETRICS."

Extract from THE AMERICAN JOURNAL OF OBSTETRICS.

"We can truly say of this magnificent work that it marks a distinct advance in the literature of Obstetrics, and we hope, for the sake of womankind, that it may find a place in the library of every practising obstetrician. It is almost encyclopedic in its scope."

"AN AMERICAN TEXT-BOOK OF APPLIED THERAPEUTICS"

AND

"AN AMERICAN TEXT-BOOK OF PHYSIOLOGY,"

although but recently issued, have met with most flattering success, and are rapidly gaining an enviable position in medical literature.

THE REASON WHY

CYCLOPEDIAS AND "SYSTEMS" QUICKLY BECOME OBSOLETE should be *self-evident.* Any Cyclopedia or "System" of practice published in a *series* of volumes running through a *succession* of years must necessarily, for the most part, become *passé*, **BECAUSE** by the time of its completion the earlier volumes practically fail to indicate the advances made in discovery and treatment of *today.*

Hence, any "System" in serial form which incompletely indicates *advanced* views is essentially useless, and is a tax upon the resources of the practitioner, **BECAUSE**, *first*, the progressive physician is compelled to supplement his "System" by purchasing later books on special subjects; and, *secondly*, as a material part of a physician's library requires to be renewed about every five years—the period, it may be, when payments on a costly "System" or a Cyclopedia have just been completed—he is obliged to incur additional expense or forego the pleasure of valuable reference-books.

THEREFORE, a physician's library the accretion of which is by one- and two-volume "text-books" written by authoritative specialists, with the gradual elimination of "out-of-date" works, not only presents the ideal of medical literature, but its renewal also becomes comparatively easy.

obstruction lasting for considerable time tends to produce collapse of the walls of the closed nasal cavity, and so chronic or permanent nasal obstruction. Syphilis, rickets, and traumatism he considers quite secondary as causes.

Nasal Splints.—Berens[1] recommends splints made from cork as being quickly and easily constructed, cheap, light, elastic, and nonconductors of heat. A cork about $1\frac{1}{4}$ in. long is cut down to the shape of an almond, with flattened side for the septum. With drill or trephine it is hollowed out, leaving a shell from $\frac{1}{16}$ to $\frac{1}{8}$ in. thick. This is coated with iodoform-collodion. These splints can be cleaned in place by hydrogen dioxid or boric-acid solution, followed by oily sprays.

Electrolysis of Nasal Spurs by Current-controller.—Casselberry[2] gives a thorough exposition of the subject of electricity as applied to nasal surgery, with especial reference to electrolysis. He concludes that cartilaginous spurs can be thoroughly removed in from 1 to 3 sittings without hemorrhage, though electrolysis does not entirely supplant surgical procedures. Hard bone is not affected by it.

Ulcerations of the Nasal Septum.—Rice[3] believes that most ulcerations of the septum following operation and in atrophic rhinitis can be cured by a thorough friction with a mild antiseptic applied on moist cotton swabs.

Perforation of the Nasal Septum.—Seiler[4] says that, while perforations of the upper bony part may be pathognomonic of syphilis, this disease is but rarely the cause when the lower or cartilaginous plate alone is affected. He ascribes local traumatism as a frequent cause—*e. g.* the mucus accumulates and becomes dry, a scab soon forms, which irritates the patient, who endeavors to remove it either by the finger-nail or by forcible blowing. Slight bleeding follows expulsion of the scab. The epithelium may thus be loosened and an abrasion results. Frequent repetition of even such a trifling loss of tissue may in the aggregate exceed the natural repair, and the depression in the septum deepens and a perforation finally results. A small opening gradually increases until it may reach a considerable size. Partial necrosis of the nasal mucous membrane, so frequently observed in typhoid fever and diphtheria, is a frequent cause of perforation of the cartilaginous septum.

Rhinophyma (Rosacea Hypertrophica).—Wende[5] contributes the portrait of a patient, a German aged 63, with an immense tumor of the nose. Twenty years ago, following typhoid fever, he noticed daily temporary flushings of face for months, when the hyperemia became permanent, with the development of numerous papules, pustules, and nodules on the face. Four years later a papule developed on the right side of the nose near the margin, and grew into the tumor. The growth was elastic, and numerous pores emitted offensive sebum. The color, once purple, was almost normal. Operation was refused.

[3] Med. News, Feb. 8, 1896.
[4] Int. Med. Mag., June, 1896.
[5] Buffalo Med. Jour., Aug., 1895.

Cancer of the Nose.—Weed[1] reports a case of epithelioma of the right nasal ala, the growth involving the cheek to within ¼ in. of the internal canthus of the right eye, cured by the application of trichloracetic acid. The patient was also directed to keep the surface moist with a 2% solution of zinc chlorid. The author believes trichloracetic acid to be the best local caustic, and that the cure was due to that agent.

Rhinoplasty.—Keegan[2] describes the plan of arranging the flaps to prevent subsequent contraction. The soft tissue is first raised in a flap from the nasal bones, beginning above and reflecting it downward; a flap is then dissected from the forehead, twisted, and placed on the nasal bones and on the raw surface of the lower flap. The lining of the nose is thus formed of skin and will not contract.

Transillumination of the Antrum.—Ohls[3] describes a new method of transillumination of the antrum by any ordinary cautery electrode protected by a 2-dram vial (Fig. 156). It can be used in connection with any

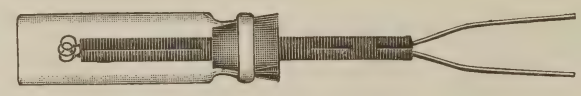

FIG. 156.—Cautery electrode.

cautery battery. Ingals[4] found that a chemical battery ordinarily used for cauterization would not heat his own transillumination incandescent lamp, but the examination was successfully accomplished by resorting to the procedure recommended by Ohls.

Empyema of the Antrum.—Cobb[5] gives the following suggestion in diagnosis: As the frontal and ethmoidal cells have their opening at their lowest parts, while the antral opening is at its highest part, it is evident that the first two sinuses are best drained when the head is in an upright position, but the antrum when the head is inverted. The patient is therefore directed, after his nostrils have been wiped clear of pus, to put his head between his knees, and if, after a few moments on assuming the erect position, the nostril is found full of pus, it has probably come from the antrum. He also states that transillumination, though sometimes useful, does not always give certain results, for the variation in the thickness of the walls of the antrum may be considerable and the skin may be too thick to transmit light well. If these methods fail, recourse must be had to exploratory puncture by the lower meatus, canine fossa, or alveolar process, the former being preferable because the wall is thin and as there is little or no reactionary inflammation.

Wright[6] quotes M. Rudaux,[7] who reports **empyema in an infant** 3 months old, due to a prematurely-developed tooth in the floor of the antrum. Seifert also refers to similar cases.[8]

Hemorrhage following Opening of the Antrum.—Scheppegrell[1] drilled through the socket of the first molar, which caused severe hemorrhage that recurred during the month following whenever the packing was removed. It is suggested that the hemorrhage was caused by the angiomatous condition of the mucous membrane of the antrum where the trephine entered.

Necrosis of the Middle Turbinated Bone.—Thrasher[2] notes the severe neuralgia due to disease of the ethmoid bone, and thinks the facial nerve has been exsected when removal of the turbinated bone was really indicated.

Sinusitis.—Myles[3] finds the ethmoid bone nearly always softened in polypoid degeneration of the frontal sinus, though not strictly in a condition of necrosis. Lichtwitz[4] tabulated the complications found with sinus-disease, based on 149 cases: 1. Nose—pseudoozena, polypi of middle meatus, caseous coryza, cacosmia; 2. Pharynx-catarrh; 3. Ears—suppurative otitis, subacute and chronic otitis, tinnitus, vertigo; 4. Eyes—dacryocystitis, exophthalmos, partial atrophic optic neuritis; 5. Nervous system—hemicrania or frontal headache, trifacial neuralgia; 6. Cutaneous system—erysipelas, eczema, acne, seborrhea, erythema; 7. Bronchopulmonary system—pseudophymia, asthma; 8. Digestive tract—gastric dilatation, enteritis; 9. Heart—pulse slackened, phlebitis.

Diagnosis of Sinusitis.—Gleitsmann[5] recommends pressure on the anterior wall and tapping the glabella in suspected frontal disease. While pointing out the uncertainties in its indications, he

says transillumination should not be omitted. Bosworth[6] describes a case of

sphenoidal disease subsequent to ethmoid disease. The ethmoid and sphenoid cells were opened with the gouge, and later with a $\frac{3}{16}$-in. drill. The sphenoidal disease lasted 13 days, followed by hemiplegia for 24 hours, indicating abscess at the base of brain, terminating in death. The author says he has seen only 2 cases of sphenoidal disease, both terminating fatally.

Dr. Ziem[1] contributed a most comprehensive paper embodying his experience in opening the antrum over 500 times. He finds that washing out the ostium maxillare is inefficient, painful, often impossible (see Figs. 157, 158), requiring cocain, which if used for a long time is liable to cause glaucoma and anosmia. Openings from the nose he disapproves of as less efficient than from the mouth, and because no improvements have been made in the operation. He advocates Cooper's method of drilling through the alveolus at the inner side of the teeth between the first and second molars or between the first molar and second bicuspid, followed by irrigation with a special force-pump.

Etiology of Postnasal Catarrh.—Freudenthal[2] repeated Aschenbrandt's experimental study on the amount of moisture absorbed by the air in passing through the nose, and decided that the air is not completely saturated. He attributes to the nasopharynx an important role in supplying moisture. In furnace-heated houses the dryness of the air causes irritation and swelling of the erectile tissues and occlusion of the nares. Normal secretion in the nasopharynx is prevented by dried secretion. The uncomfortable sensation causes one to breathe through the mouth even when the nares are free.

Catarrhal Diseases of the Nasopharynx and the Stomach.—Turk[3] discusses disease of the mouth, nose, and throat as etiologic factors in chronic glandular gastritis from bacteriologic examinations of the nasopharynx and the stomach. Specimens were obtained by the gyromele, a revolving sponge protected by a catheter or tube. In the anterior nares all forms of bacteria were found, but not colonizing; in the nasopharynx, when chronic inflammation existed, almost pure cultures were found. The lymph-cells from the vault of the pharynx act as phagocytes carrying infection to the stomach. He gives a number of cases in which treatment of the nares and nasopharynx relieved or cured gastritis by stopping infection.

Tuberculosis of the Nasopharynx.—De Mochowski[4] found that the mucous membrane of the nasopharynx was diseased in 21 out of 64 tuberculous patients examined. The 21 were mostly cases of acute miliary tuberculosis. [This is a remarkably large percentage. According to our observations, the nasopharyngeal mucous membrane is but seldom involved.]

Adenoid Hypertrophy.—Schadle[5] in a beautifully-illustrated article shows a variety of hypertrophies of the postnasal adenoid tissues. He characterizes as criminal the advice of some family physicians to let the child outgrow the difficulty.

[4] Gazeta lekarska, 1895, 2–4, quoted in Quart. Med. Jour., Jan., 1896.
[5] The Laryngoscope, vol. i. No. 1, July, 1896.

Adenoids and Incontinence.—Gronbeck[1] states that of 192 children with adenoids, 24 had incontinence; of 23 operated upon, 12 were cured at once; in 7 not operated on the incontinence disappeared when nasal breathing was reestablished. He thinks incontinence is due to CO_2 poisoning.

Results of Adenoids in Children.—Eustace Smith[2] states that the weakened state is due to a tendency to take cold on account of a susceptibility to changes of temperature. Gastric derangement with chronic dyspepsia and malnutrition follows. In neurotic and phthisical children operation is indispensable. The late Dr. Wilhelm Meyer[3] addressed the Copenhagen Medical Society on the antiquity and universality of adenoids. In Greenland, Dr. Helms reported 23 out of 60 children had the typical adenoid face, and only 16 were free from it. It is common among North American Indians and in South Americans of European descent. Semon[4] describes the symptoms, and advises early removal on account of health, mental development, and formation of the face, to prevent ear-complications, and to avoid increased danger of zymotic diseases in this condition. He reviews the different methods of operation, and recommends chloroform anesthesia sufficient to relax the muscles, but not to abolish the cough-reflex. He advises the use of small instruments in children. When associated with enlarged tonsils he recommends removal of the tonsils first, and operation on the adenoids after the throat is healed. [We advise complete anesthesia, a thorough operation, and removal of the faucial tonsils at the same time.] Arslan[5] reported 426 cases out of 4080 cases of diseases of the nose, throat, and ear; 69% had nasal obstruction; 37 had tonsillitis or pharyngitis; 59 had ear-complications; 110 were cases of suppurative otitis, and 142 had deafness with suppuration; 2 out of 6 deaf-mutes were improved by operation. Heredity was noted in 60%. The age of the patients was up to 40.

Stammering due to Adenoids.—Delavan[6] notes that certain defects of speech, such as mispronunciation of the consonants, depends upon obstruction in the normal resonating cavities, and that after removal of adenoids the defects have disappeared. Marked relaxation of the throat may cause the same defect, or even stammering, which may recur upon the relaxation of the soft palate due to an acute cold. Frequent gargling with cold water, head-tones, and falsetto-tones are advised to strengthen the levators of the palate.

Vertigo of Nasopharyngeal Origin.—Scheppegrell[7] describes a case in which vertigo was induced by retronasal catarrh. The patient, a man 24 years of age, for 7 years past has suffered from catarrh, but for the last 2 years, while making an attempt to clear his throat (nasopharynx) after breakfast, he gags and becomes dizzy, and has to take hold of a chair or other article

[1] Arch. f. Laryn., ii. p. 214; Am. Med.-Surg. Bull., Dec. 1, 1895.

[6] N. Y. Med. Jour., Sept. 21, 1895.
[7] Med. News, May 23, 1896.

to prevent himself from falling. On two occasions he completely lost consciousness. Recently he has also had great pain over his right eye. A rhinoscopic examination showed a cartilaginous thickening of the septum into the right nostril and hypertrophy of the mucous membrane, causing marked stenosis. The septal thickening was removed and the hypertrophied mucous membrane reduced by the electrocautery. When the treatment was advanced the patient improved. Eight months later he reported having had no recurrence of either vertigo or pain.

Multiple Benign Papillomata of the Buccal Mucous Membrane.—Rasch[1] reports 2 cases in which a number of warty or condylomatous growths were found on the inner side of the lower lip and cheeks, varying in size from a flaxseed to a lentil. When touched or during mastication the larger bled easily. Applications of Paquelin's thermocautery destroyed the growth. In 1 case the child was in the habit of sucking the thumb, on which she had an old-standing wart.

Mouth-breathing and Salivary Calculus.—Guye[2] considers the formation of salivary calculus over the outside of inferior incisors a stigma of mouth-breathing. At that point the saliva becomes rapidly desiccated in mouth-breathers and the lime-salts are precipitated.

Xerostoma.—Riesman[3] reports a case in a woman of 38 with frontal and occipital headache, constipation, cramps, and a dry, pasty feeling in the mouth and throat, and burning pains in the tongue, also a burning sensation along the inferior maxillary nerve. The tongue was red, bare, and beefy, and studded with petechial hemorrhages on the under surface. Treatment failed to give any relief. Chappell[4] reports a case of his own, and also 1 of Robinson and 1 of Richardson. His patient, a woman of 46, gave a history of gradually-increasing dryness of the mouth, extending to the tongue, pharynx, larynx, trachea, and nares. The attacks were intensified during the menses at first; later the menses ceased. The parotid, submaxillary, and cervical glands became enlarged. The teeth decayed early in the disease and were removed. Thirst was constant, constipation extreme, and taste and smell impaired. Three months' treatment with nerve-tonics, potassium iodid, and pilocarpin produced some improvement. A year later death followed an attack of hemiplegia. Robinson's case was that of a woman who for several years felt constant pain in the roof of the mouth, which was relieved by anything causing a flow of saliva. She had gouty joints, which were relieved by colchicum and sodium salicylate. Pain extended to the mouth, jaw, and tongue, and was not relieved by potassium chlorate, strophanthus, or other remedies. Richardson's case was in a single woman of 60 who had suffered 4 years with nervous prostration. She had acquired the habit of taking camphor for headaches; her teeth decayed and dryness of the mouth supervened. The salivary glands were apparently unchanged. The urine was copious and of low specific gravity. Galvanism

[1] Quoted in Ann. of Ophth. and Otol., Oct. 18, 1895.
[2] Jour. of Laryn., July, 1895.
[3] Phila. Polyclinic, Mar. 7, 1896.
[4] N. Y. Med. Jour., Feb. 29, 1896.

and faradism of glands were without effect. Pilocarpin, gr. $\frac{1}{15}$ to $\frac{1}{10}$ every 2 or 3 hours, produced a fair amount of moisture in mouth.

Cleft-palate Operation.—Kraske [1] describes a new operation on a patient of 20 with extensive cleft. He cuts off the inferior turbinated bone, except the posterior $\frac{1}{3}$ in., with curved scissors. The turbinated is then used as a flap, and may be twisted and stitched to the margin in front or behind. The pedicle may be severed with the cold snare after from 10 to 14 days. [A very ingenious operation, but probably applicable only in selected cases.]

Acute Inflammation of the Lingual Tonsil.—Beausoleil [2] says acute inflammation is sudden, with cephalalgia, fever, pain on deglutition often below the lesion at the sternal fourchet or radiating to the ears. The tonsil is covered with white exudate and the disease ends in suppuration. Abscesses must be opened and iodin, trichloracetic acid, or resorcin applied to reduce hypertrophy. The galvanocautery may be necessary. Lewis [3] notes the common occurrence of diseases of the lingual tonsils and the symptoms—cough, fulness or tightness of the throat, dryness, and a rough, scratchy feeling. The lymphoid tissue and follicles may be found swollen and hypertrophied on one or both sides. Varicose veins may give rise to alarming hemorrhage. The tip of the epiglottis may be caught among the masses, causing a severe cough, which with the hemorrhage might seem to suggest serious pulmonary or laryngeal disease. The feeling of fulness in the throat may simulate globus hystericus. Solutions of iodin applied upon a swab with the tongue protruded in many cases cause atrophy of the enlargement; others require removal. Tompkins [4] notes that this form of lymphatic hypertrophy in the glossoepiglottic fossa is more common in middle life and in women. It is a chronic development. The most important symptom is a dry cough. By interfering with the movements of the epiglottis it causes fatigue in speaking or singing. Tickling sensations, suffocative attacks, and severe dyspnea have all been noted. He recommends

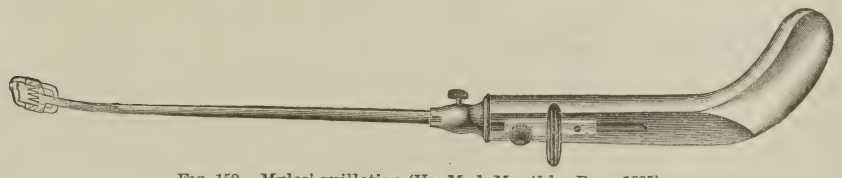

FIG. 159.—Myles' guillotine (Va. Med. Monthly, Dec., 1895).

removal of the growth in 2 or 3 sittings with the guillotine devised by Myles (Fig. 159), which leaves the throat in better condition than the galvanocautery, which is difficult. When removal does not relieve the cough, there will usually be found varicose veins on the base of the tongue. The largest of these should be destroyed by the galvanocautery.

Identity of Septic Throat-inflammations.—Semon [5] upheld the probable pathologic identity of acute edema of the larynx, edematous laryngitis,

[1] Beit. f. klin. Chir., xiv. ii. p. 577.
[2] Rev. de Laryn., Dec. 1, 1895.

[4] Va. Med. Monthly, Dec., 1895.
[5] Brit. Med. Jour., quoted in Pacific Med. Jour., Oct., 1895.

erysipelas of the pharynx and larynx, phlegmon of the pharynx and larynx, and angina Ludovici. In 1882 he had maintained that myxedema, cachexia strumipriva, and cretinism were due to the same lesion.

Bacteria of Tonsillitis.—Kelley[1] relates 4 cases of infection from a case of tonsillitis in which cultures showed only staphylococci and streptococci. Meyer[2] states that the secretion from noninflamed tonsils contains a coccus similar to streptococcus pyogenes, staphylococci, and leptothrix. Of 55 cases of inflammation, he found streptococci in 40, and believes them to be the cause in a large majority. He has never found pneumococci.

The Rheumatic Diathesis in Acute Tonsillitis.—Hope[3] questions the dependence of acute tonsillitis on the rheumatic diathesis, and claims that in a large clinical experience he finds cases answering to a rheumatic history exceptional, although specially examined by advocates of the rheumatic theory. If local acute manifestations of the rheumatic state occur, he would look for them in serofibrous tissues, rather than in mucofibrous tissues like the tonsils. In later life the tonsil becomes less and less subject to inflammation, while the gouty and rheumatic age is more confirmed. In suppurative periamygdalitis the course and termination point toward an infectious origin, with which a rheumatic connection is purely accidental. The average duration of 5 to 7 days for the amygdalitis of ordinary severity is little if any abbreviated by the early and vigorous use of antirheumatic remedies.

The Tonsils and Middle-ear Disease.—Ferrari and Garbini[4] attribute many cases of acute purulent otitis media following minor operations on the throat to infections from the tonsil. They advise disinfecting the mouth and nasopharynx and removing the tonsils by tonsillotomy, rather than destruction of hypertrophies by ignipuncture or galvanocautery, which is liable to open new channels of infection. Koehler[5] ascribes certain cases of tonsillar abscess to chronic suppurative middle-ear disease, the pus running into the pharynx through the Eustachian tubes. In one case a long series of abscesses in the tonsil ceased on proper treatment of the ear-disease.

Etiology of Lacunar Tonsillitis.—Coolidge[6] quotes Fränkel, who noted the cases of tonsillitis following intranasal operations, especially by the galvanocautery. He believes that tonsillitis arises from infections through lymph-channels from the nose and other regions more often than through the same channels by which the leukocytes escape. Chill may cause it by diminishing resistance or by causing catarrh, which affects the tonsil through the lymphatics.

Chancriform and Ulcerative Tonsillitis.—Mendel[7] describes an unusual condition which he had observed 6 times. It is a slowly-developing tonsillitis ending in a circular ulcer, more or less punched out, covered with a

[7] Rev. de Laryn., Sept. 15, 1895.

dirty white coat and surrounded by a congested area. This remains stationary for a short time, but usually heals in about a week. From a chancre the condition is to be distinguished by the limited enlargement of the lymphatics and by its more rapid development. He believes it should be classed as a particular form of herpes, the vesicular form of which had passed unnoticed. [The rapid healing of this ulcer also distinguishes it from the specific one—a fact that should be borne in mind. The tendency of physicians, particularly those who have been only a few years in practice, is to look constantly for unusual diseases, and thus very often will marked cases of syphilitic ulceration go unrecognized for months.]

Chronic Disease of the Tonsils.—Wilson [1] says if hypertrophy is not a factor in the production of sore throat, and is apparently doing no harm, he leaves it alone. If the crypts alone are diseased, he cauterizes them. In cauterizing them he inserts the electrode diagonally, which also reduces the hypertrophy. For mycosis he recommends curetting and frequent application of sodium salicylate in alcohol. Kendal [2] believes that in every case of acute or chronic inflammation of the tonsils the salivary secretion will be found acid instead of alkaline, and that free doses of potassium carbonate or soda internally and locally applied will give most rapid relief. For cauterizing enlarged tonsils he recommends hydrochloric acid applied by a long capillary tube to the excretory ducts of the tonsils, 3 in each gland, at a sitting twice a week. This is painless and produces no inflammation or swelling. Five or six applications are sufficient for moderately enlarged tonsils. Nitric acid used in the same way will produce swelling and sloughing. Chromic acid he has abandoned after producing tetanus in a malignant case. Fenn [3] reported a case in which the tonsils were elongated till they touched the epiglottis, causing hysterical dyspnea. Removing a large piece from each tonsil gave immediate relief. Lichtwitz [4] has removed 400 tonsils with the hot wire. It is easy to do, and there is no danger of hemorrhage or of wounding the anterior fold. [Absence of hemorrhage makes this a desirable procedure in some cases, but the slowness of the operation and the pain would render it very objectionable when a general anesthetic was not used, and the severe reaction from the burn would add greatly to the patient's discomfort.]

Polypoid Hypertrophy of the Tonsil.—Lemariey [5] describes a case in which removal was easily effected by the hot snare. Under the microscope the growth appeared to be tonsillar tissue, except that under the mucous membrane connective tissues were so greatly developed at points as to resemble a true sclerosis. These growths may assume either a fibrous or lymphoid type.

Tuberculosis of the Tonsils.—Stewart [6] gives a case as one of ordinary enlargement of the tonsils, with pharyngeal adenoids associated with post-scarlatinal otorrhea and enlargement of the cervical lymphatic glands, in a child 10 years old. Section of lymphatic tissue from the tonsils showed

numerous tuberculous giant-cell systems, but no tubercle-bacilli. Some enlarged cervical glands removed subsequently showed typical tuberculosis in various stages. Dieulafoy[1] found tuberculosis in 13% of cases with simple hypertrophied tonsillar tissue, and in 20% of adenoids. He notes that faucial and lingual tonsils can be inoculated by swallowing tuberculous material.

Syphilis of the Tonsils.—Fournier[2] claims that chancre of the tonsil is far more frequent than it is supposed to be—that he himself had for a long time mistaken it for other lesions. Boeck calls it the most common of all extragenital chancres, and accounts for its frequency in Norway by the great number of poor families using the same vessel for eating, some of them having but one spoon for the whole household.

Pharyngotherapy.—Heller[3] notes the frequent infections in this region, and recommends nasal and nasopharyngeal irrigation in erysipelas, diphtheria, pertussis, scarlatina, measles, rötheln, typhoid, etc., either with sterilized water or some mild antiseptic. He says: 1. A majority of infectious diseases, excepting cholera and dysentery, are inhalation-infections; 2. The first localization of disease is in the upper air-passages; 3. This region forms a situation where the incubation-period is completed; 4. Absorption into the blood and lymphatic current takes place from here. [Undoubtedly useful in a few cases where nonirritating solutions are employed, and sufficient care is exercised to prevent entrance of the solution into the Eustachian tubes, but should not be employed indiscriminately.]

Fatal Pharyngeal Hemorrhage.—Brewer[4] reported a case diagnosed as quinsy with repeated severe hemorrhages, from the effect of which the patient died.

Syphilitic Adhesions of the Pharynx and Soft Palate.—Lieven[5] advises that after separating syphilitic adhesions the posterior nares be powdered with europhen and packed with europhen gauze for 10 days. Then a rubber bag is passed into the nasopharynx with a tube extending through the nares, by which the bag is distended with air. This may be worn for several hours a day at first.

Mycosis of the Throat and Nose.—Wright[6] contributed 4 cases. In the first, a young girl, the tonsils, pharynx, and nasopharynx were covered with numerous mycelial threads showing lepthothrix buccalis. All the growths disappeared within 2 weeks, the patient meantime using an alkaline douche. A few plugs in the tonsils were touched several times with solution of iodin. He condemns surface applications. A case of mycosis is reported in the Virginia Medical Monthly for July, 1895, in which an attack of pneumonia was followed by complete disappearance of numerous mycotic masses without local treatment. [We have known them to disappear even without the intervention of pneumonia or other disease, and without treatment.]

Chronic Spasm of the Pharynx.—Bond[1] noted rhythmic movements of the back of the pharynx to the left and returning to the middle line, the soft palate being drawn up at the same time and relaxed. No clicking sounds were heard by the patient or others.

Treatment of Pharyngitis.—Burgess[2] reports a case in which repeated severe hemorrhages occurred from a sulcus in the tonsil. Treatment by ergotin and ice was inefficient. Blondian[3] in the dry form of pharyngitis uses friction with a 30% solution of sodium sulphoricinate. Under cocain the mucous membrane may be scarified, and the application then made to penetrate to submucous tissues. He finds that it restores the normal secreting function.

Retropharyngeal Abscess.—Levrey and Ghika[4] report a case of retropharyngeal abscess in a child of 6 months. Median incision gave exit to pus, which escaped from the mouth and nose, the head being inclined forward. The child ceased breathing, although on autopsy no pus was found in the larynx, trachea, or bronchial tubes. Koplik[5] reviews an experience of 77 cases within 6 years, a majority of which were infants under 2 years of age and most frequent during the period of suckling. He divides the subject into —1. Acute retropharyngeal abscess; 2. Chronic; 3. Septic. He denies the possibility of an acute idiopathic variety, and maintains that they are all due to infection through the lymph-channels of the adjoining structures. Willy Meyer[6] advocates the incision of nonperforating abscess from the side of the neck on antiseptic principles. In cases of septic origin irrigation and drainage are facilitated. In tuberculous cases curetting and packing with iodoform-gauze are made possible. He describes Burckhart's operation—an incision at the inner border of the sternomastoid at the level of the larynx, dissecting to the inner side of the common carotid, and incision of the thickened mass beside the lower end of the pharynx, enlarging the opening with the dressing-forceps. He describes 4 cases of this operation, but admits that the preference between this and Chiene's incision behind the sternomastoid is undecided. Hand[7] describes a case following parotitis in a boy of 22 months. The abscess was 3 weeks developing, and was opened by direct incision from the pharynx.

Cervical Tubercular Adenitis.—Ingals[8] recommends guaiacol and carbonate of creasote internally, with phenol and lactic acids injected into the suppurating glands. He related the case of a man of 33 who developed an adenitis during treatment for phthisis; 4 injections of the acids within 9 weeks, after withdrawing the contents of the abscess, caused complete healing. Injection was begun with 3% of phenol and 20% of lactic acid. The strength of subsequent injections was gradually increased to 5% of phenol and 40% of lactic acid; the phenol prevented severe pain.

Thyroid Cyst.—Brown[9] enucleated 2 cysts in young women after emptying the contents through a free incision.

Goiter.—Morris[1] has treated 55 cases in the past 2½ years. The soil in his district is excessively chalky, and the water-supply is obtained from deep wells in the chalk. The author attributes goiter to the presence of calcium and magnesian carbonate in the water. People living on the hills and using rain-water were not affected with the disease. Munson[2] in a report on goiter among the Indians in the United States found 1823 cases among the 77,000 inhabitants of goitrous tracts. He concludes—1. There is a strong racial predisposition to goiter among Indians; 2. It is a distinctly localized disease; 3. It does not appear to be caused by high altitude, climate, or water containing an excess of calcium salts; 4. It is favored by unsanitary conditions, constitutional depression, and excessively nitrogenous diet; 5. Hereditary influence is strongly marked; 6. Cretinism and Graves' disease are rare; 7. The tumors are smaller than among the whites. Mikulicz[3] reports 10 cures of goiter and 1 of Graves' disease. He gave raw chopped sheep thymus in from 10- to 25-g. doses on alternate days. In 6 cases much diminution in size occurred within 2 or 3 weeks, without the malaise, loss of flesh, diuresis, or rapid pulse reported in thyroid-feeding. In the case of Graves' disease in a woman of 44 there was imminent suffocation, with cyanosis and rapid pulse, all relieved by the injection within 6 weeks of 375 g. of thymus.

Thyroid Extracts and Desiccated Thyroids.—Ingals and Ohls[4] from an analysis of 50 cases find that swelling was reduced in 38, not affected in 11, no report in 1. These remedies produce marked physiologic effects upon the nervous and circulatory systems, as indicated by headache, dizziness, pains in other portions of body, great weakness, and by flushing of the face and rapidity of the heart's action. Some of these symptoms usually occur when the daily dose corresponds to 1½ or 2 entire thyroid glands of the sheep. Desiccated glands appear quite as active as the liquid extracts, and are more stable. Internal administration appears quite as effective as hypodermic use. They recommend 2-gr. doses of the desiccated gland 3 times a day. Loss of weight is so variable that it is probably due to disturbance of the digestive organs. Cystic growths in the thyroid gland are probably not influenced.

Graves' Disease.—Pribram[5] has noted gradual subsidence of the cardinal symptoms in Graves' disease for long periods. In such cases complete recovery may be claimed. These facts should be remembered when the operative or medicinal treatment of Graves' disease is under consideration. Singer[6] reports a case of scleroderma in which the right half of the thyroid gland was found greatly atrophied during life, and, postmortem, both lobes showed marked sclerotic changes. He suggests, therefore, that Graves' disease, myxedema, and scleroderma are related. Ingals and Ohls[7] found that desiccated thyroids caused rapid reduction in the size of the gland in this disease, but the remedy aggravates the heart-symptoms, and it must therefore be given care-

fully. The exophthalmos was not appreciably affected. Scholz[1] has noted the excretion of phosphoric acid in the feces during the ingestion of thyroids. In Graves' disease the amount excreted in the stools amounted to tenfold the normal, as compared with an increase of 25% only in a healthy person. He concludes, therefore, that the thyroid gland has an important influence on the metabolism of phosphoric acid, and suggests that the failure in the function of the thyroid causes retention of phosphoric acid, while the morbidly increased activity as in Graves' disease caused increased excretion. Kocher, by similar reasoning, recommended the internal use of sodium phosphate in this condition.

Partial Thyroidectomy.—Tuffier[2] gives a case of severe exophthalmic goiter with cystic enlargement of the right lobe of the thyroid in a woman of 27. Iodin-injections, tapping, and electricity caused no improvement. The exophthalmos and other symptoms disappeared after partial thyroidectomy.

Foreign Bodies in the Esophagus.—Allen[3] studied 82 cases recorded in the Surgeon General's office. As to the relative importance of symptoms, he divides the esophagus into four portions. The voice is harsh, metallic, or chirping, while stridor is less frequent than one might expect. When the foreign body is lodged in the neighborhood of the glands of the pharynx and mouth excessive mucous formation takes place. Primary hemorrhage is not usually important, but secondary hemorrhage indicates ulceration or injury of the large vessels. Anxiety is marked. Belching is a rare but grave symptom; pain is variable and referred to the cervical vertebræ, the epigastrium, or to the base of neck. Convulsions occur occasionally. Emphysema occurs in 15% of cases. Various reflex neuroses have been noted.

Fracture of the Hyoid.—Ramsden[4] gives a unique case of indirect fracture of the hyoid bone from a fall on the head. There was hemiatrophy of the tongue, with difficult speech and swallowing, which improved for 8 years. Fibrous union of the hyoid occurred.

The Epiglottis.—Barrett[5] quoted Prof. Anderson Stuart of Sydney, whose patient had an injury of the neck exposing the epiglottis and larynx. During deglutition the epiglottis remained erect, and the closure of the larynx was effected by the approximation of the true and false vocal bands. The epiglottis probably played the part simply of a shute which directed the food toward either side in its passage down the dorsum of the tongue. [The wound of the neck doubtless interfered with the normal action of the parts; therefore this observation should not be considered as conclusive.]

The following case is from an editorial in the Virginia Medical Monthly for July, 1895: A patient felt a bone in the throat after eating fish; 4 days later an abscess formed on the anterior surface of the epiglottis, and was supposed to be the cause of the sensation. The abscess was opened, and the fol-

lowing day another small abscess was opened and a solution of silver nitrate applied without relief. Further examination then revealed a small fish-bone projecting from the base of the tongue, and it was removed by the wire snare passed through a curved cannula with flattened end.

Rosenbaum [1] reports a case in which Israel removed the entire epiglottis for malignant disease from a man of 64, with recovery. Within 3 weeks he could swallow solid food and speech was not affected. Incision was made close to the lower border of the hyoid bone to avoid injury to the superior laryngeal nerve.

Kirstein's Direct Laryngoscopy.—Bruns [2] described the new method of examining the larynx by direct inspection (see Figs. 160, 161), and said

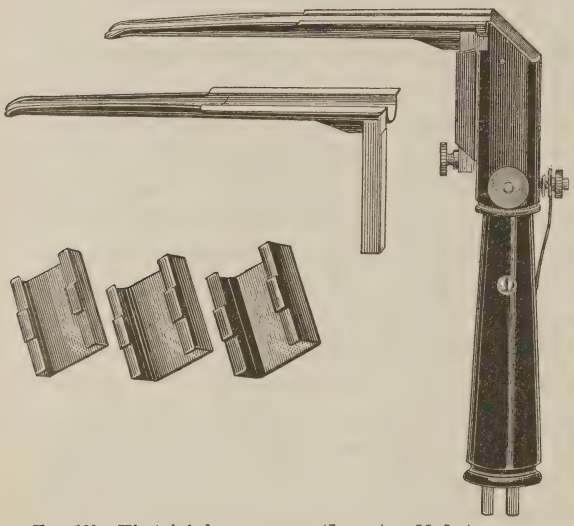

FIG. 160.—Kirstein's laryngoscope (Jour. Am. Med. Assoc., Feb. 8, 1896).

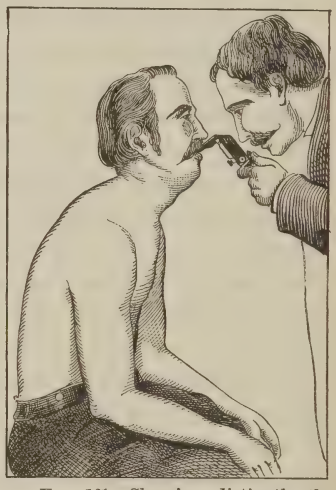

FIG. 161.—Showing distinctly the position of neck and head during examination (Jour. Am. Med. Assoc., Feb. 8, 1896).

that it can be used in about one-half the cases, anatomic conditions not permitting it in others. Growths can be removed endolaryngeally by this means, and, while it is only exceptionally useful in adults, the writer found that it was valuable in most cases of children. Children during the earlier years may be held during the operation, while adults may be given short narcosis. [This must generally be much less satisfactory than the usual method, but in operating on children under an anesthetic it would appear worthy of trial.]

External Examination of the Larynx.—Gerhardt [3] gives the diagnostic points to be noted by manipulation of the larynx and front of the neck. In severe dyspnea from narrowing of the caliber of the larynx the latter manifests strong movements synchronous with respiration, while in tracheal stenosis

[1] Arch. f. klin. Med., 1895, xlix. p. 773, quoted in Am. Med.-Surg. Bull., Aug. 15, 1895.

it is generally quiet. In the former case the head is generally bent backward, while in the latter the chin approaches the sternum. In persistent stridor the finger placed lightly on the cervical portion of the trachea feels a corresponding whirring, which in laryngeal obstruction is more often inspiratory, or at least stronger in inspiration, while in deep-seated tracheal trouble the after-felt whirring is more often expiratory.

X-Rays and the Larynx.—Wagget[1] reported that together with Rowland he had been enabled by the use of the cryptoscope to not only locate foreign bodies in the larynx and esophagus, but to see the relative position of a probe and the foreign body. MacIntyre[2] in a preliminary note on the use of the Röntgen rays states that with an App's coil and Newton's tube he has seen shadows of the vertebral column, ribs, clavicle, and scapula. A photograph of the larynx shows the base of tongue, hyoid bone, thyroid and cricoid cartilages, epiglottis, and other details. Foreign bodies and ossification of cartilages have been detected in dead bodies. With the cryptoscope he has seen a coin swallowed 6 months before lying at the level of the third dorsal vertebra. For examination of the antrum he uses Crookes' tube outside, with a special cryptoscopic tongue-depressor.

Function of the Laryngeal Ventricles.—Hodgkinson[3] states that the laryngeal ventricles act as receptacles for dust and mucus cleared off the vocal cords by their vibration. The observed passage of mucus, etc. from the ventricles downward into the air-passages proves that blood, pus, etc. coughed up from these passages may be of other than pulmonary origin. The clearing of the cords and ventricles by the ordinary act of deglutition helps to explain the clearing of the voice by eating, drinking, etc.

Laryngeal Ventricle-prolapse.—Jones'[4] patient, a male of 35, after overstrain of the vocal cords outdoors felt sudden impairment of the voice, quickly disappearing, but returning in a fortnight. Examination showed a reddish mass resting on the left vocal band. The ventricle prolapsed gradually when the attachment to the thyroarytenoid muscle and connective tissue gave way. The mass could be replaced by pressure. He removed it by galvanocautery, with a shield to protect the vocal band.

The Cigaret Habit and Laryngitis.—Mulhall[5] ascribed the evil effects of cigaret-smoking to nicotin alone, and its pleasure to irritation of the laryngeal and tracheal sensory branches of the pneumogastric. Locally, it never causes throat-diseases, though it may aggravate them either locally or by its constitutional depressing effects. On youth he finds it invariably harmful.

Laryngitis Sicca.—Wright[6] quotes M. Molinie,[7] who says that laryngitis sicca may be primary and developed independently of any lesion of the nose and nasopharynx. He attributes it to the coccus of Loewenburg. Wright attributes all chronic laryngitis to disease of the air-passages above,

[7] In Rev. de Laryn.

except those due to alcoholism, overuse of the voice, or rheumatism. He has never seen tracheal ozena without ozena and atrophy of the nasal mucosa. He believes that the crusts are dried secretions which come from above in semifluid form. [We have seen tracheal ozena with normal nasal passages.]

Laryngeal Ulcers in Typhoid Fever.—Bergengrün[1] noted marked swelling of the epiglottis, edema of the arytenoid cartilages, and both vocal bands almost entirely destroyed, by deep ulcers. From study of this case he concludes that the laryngeal complication is not due to decubitus, but to a secondary infection of the larynx as advocated by Rokitansky. Kanthack[2] read a paper written by himself and Drysdale, based on 61 postmortems from 1890 to 1895. Ulceration was found in about 26%, generally over the tip and edges of the epiglottis and in the neighborhood of the processus vocalis. In 14 cases the epiglottis alone was affected in 4, the larynx proper in 7; both larynx and epiglottis once; in 2 cases the soft palate or pharynx was ulcerated, as well as the epiglottis. In many or most of the cases the patient was in the typhoid state, which predisposes to ulceration, the laryngeal mucosa being then readily injured and forming a portal for pyococci rather than typhoid-bacilli. Typhoid fever probably renders the laryngeal mucosa more vulnerable to attacks of the tubercle-bacillus.

Laryngeal Fractures.—Scheff[3] describes the symptoms including general subcutaneous emphysema. Crepitation is difficult to distinguish from that obtained by pressing the normal larynx against vertebræ. The thyroid cartilage is fractured more often than the cricoid. The arytenoids and vocal membranes may be involved. The partial ossification of middle age predisposes.

Lepra of the Larynx.—Bergengrün[4] gives a microscopic description of 9 cases, in all of which the epiglottis, the true and false vocal bands, were involved. The epithelium was swollen and covered with nodules. The cartilages appeared normal, but the perichondrium was irritated and sometimes swollen.

Polypoid Lipoma.—Farlow[5] reported a male of 66 with a growth of 15 years' duration. The growth was attached to the lower pharynx, and by coughing with the head held downward it would extend ½ in. out of the mouth, and part of it would drop between the vocal bands. There was no recurrence within 3 months.

Edema of the Larynx.—Levi and Laurens[6] described a patient, a male of 34, with intense dyspnea and cyanosis, edema of the epiglottis and arytenoepiglottidean ligaments. Cure followed leeching the front of the neck.

Stenosis of the Larynx.—Massei[7] gives a review of operations with the following conclusion: In cases of severe stenosis in which tracheotomy is clearly indicated, but time would not allow of its performance, temporary in-

tubation, provided the form of the stricture allows of the passage of the tube, will render the operation easier, not only by removing the immediate danger of suffocation, but also by fixing the larynx and quieting the circulation.

Intubation.—Variot[1] gives the record of 4 cases in which, after intubation, the metallic tube was accidentally swallowed. The author maintains that, notwithstanding their size, the tubes when they are swallowed may pass through the entire digestive tract and be eliminated without causing any trouble. In children dead of diphtheria, tubes have been found in various parts of the gastrointestinal tract, which tubes were doing no harm and would eventually have passed. Out of 857 cases of diphtheria treated by Variot, 122 were intubated, although the introduction of the vapor-room has greatly diminished the necessity of the procedure. Of the 4 cases in which the tube was swallowed, 1 passed it in 2 days, and 1 passed it in 3 days, while the other 2 perished because of the disease and not because of the tube. The autopsy disclosed the tube in 1 case in the stomach, and in the other case in the cecum. Mayo[2] reports a very interesting case in which an intubation-tube slipped into the bronchus and was removed by a tracheotomy, the patient recovering. In this case the tube was inserted without any difficulty. Mayo used the size of tube advocated by O'Dwyer for children from 4 to 6 years of age. At the end of the third day the condition had so much improved that the tube was removed. Three hours later he was forced to reinsert the tube because of dyspnea. Again in 2 days the tube was removed, but 6 hours later it was again reinserted because of threatened suffocation. After the tube had remained about 42 hours, it was observed that the breathing was difficult and very noisy. Mayo introduced his finger and was unable to feel the head of the tube, and he detected the fact that swelling and edema of the larynx and adjacent structures had disappeared. Reaching far over into the esophagus, the head of the tube could be felt in the trachea below the cords. The trachea was compressed about the tube and forced up. The extractor was introduced into the larynx, and the tube was held forward by a finger behind the larynx. During attempts at extraction the tube was felt to slip down into the bronchus. Suffocation seemed imminent, and it became evident that the tube must be at once removed. The incision for a low tracheotomy was made. The trachea was opened, the assistant held the child up by the feet, and artificial respiration was made. A probe was introduced, and the tube was discovered in the right bronchus. The probe loosened the tube, and the manipulation brought on a cough which forced the tube down to the incision, through which it was easily withdrawn. After 15 minutes respiration became natural. The child soon returned to consciousness, and a tracheotomy-tube was inserted and left in place for 6 days. In spite of a septic bronchopneumonia, the child made a good recovery. [This case is in every way creditable to the skill, courage, and persistence of the surgeon.] Strong[3] reviews his experience in 100 intubations, in which he introduced the tube about 300 times. To intubate, have the child

[1] Jour. de Clin. et de Thérap. infant., May 30, 1895.

[2] Med. Rec., Nov. 2, 1895.

[3] Chicago Med. Recorder, Sept., 1895.

sitting upright with head held back, so that the mouth looks straight upward. In this position he seldom fails in the first attempt to introduce the tube. After intubation he confines the diet to milk and water from a nursing-bottle, the patient lying on the back with the head lower than the body. Since feeding the patient as described he has had 56 cases of intubation in diphtheria with 26 recoveries. [The position recommended for the patient when intubation is to be done differs from that generally recommended, and deserves trial, though we have had much more difficulty in doing the operation when the head was thrown backward more than 20° from the axis of the body.] Bartlett[1] reports 61 cases intubated, with 20 recoveries. Of patients over 3 years old, 47.8% recovered.

Wetherla's Extractor.—Wetherla[2] describes an electromagnetic tube-extractor. When attached to cautery batteries of 6 volts the lifting power is entirely sufficient. The tube should be of iron or the head may be of iron and the body brass. [Although this instrument can be used satisfactorily if properly made and connected with a suitable battery in good working order, it seems to unnecessarily complicate a simple operation.]

Multiple Laryngeal Papillomata.—Von Navratil[3] relates 42 cases of children whose larynges were extensively filled. He advises complete removal in every case to avoid recurrence if possible. If growths are single or small, they can be removed by intralaryngeal curetting, or, if dyspnea is urgent, after tracheotomy. Extensive growths require laryngofissure and thorough removal of masses, both to restore speech and to prevent recurrence. If dyspnea was not urgent, he began removal with Storck's guillotine, finishing with the sharp spoon, without narcosis, and before cocain without a local anesthetic. Recurrence always took place, requiring a repetition of the operation at intervals for a period of from 1 to 4 years till power of recurrence was exhausted. Recently he had done tracheotomy, followed by intralaryngeal removal, and on recurrence he removed them from above and also through the tracheotomy fistula. In 15 adult cases on recurrence after curetting he performed laryngofissure and removed growths without recurrence. Kanthack[4] exhibited before the Laryngological Society of London the larynx of a child that had died suddenly of asphyxia. The whole internal surface of the larynx was filled with a dense papillomatous growth below the band, and even below the tracheotomy-wound. The growths were covered by a thick layer of squamous epithelium. Delavan[5] said that at least 3 cases have been cured by frequently-repeated sprays of absolute alcohol. The applications are easily made, are nonirritating, and apparently are not followed by recurrence.

Benign Tumors of the Larynx.—Rousseaux[6] from experience in 2 cases concludes that the galvanocautery is applicable to the larynx, contrary to

the view generally held. Especially is it indicated in sessile benign tumors of small dimensions. The cautery-point must be smaller than the neoplasm, and applied near the center of the latter for not more than a second. The heat should be dull-red only. [The cautery, accurately applied, with a sufficient interval (14 to 20 days) between operations, may be very useful in selected cases.]

Lupus of the Larynx and Palate.—Stabb[1] presented a case of this disease to the Laryngological Society of London. McBride had used the galvanocautery and chromic acid successfully in such cases. Semon preferred scraping and lactic acid when the parts were accessible, but feared that stenosis might follow scraping the larynx. He had treated some with arsenic and cod-liver oil without local remedies. Stewart's case improved under arsenic alone.

Myxoma.—Bond[2] reported that he had removed a cyst-like myxoma from the middle of the right vocal band. The patient had been hoarse 12 years, and the voice was much improved by the operation. Pure myxomas of the band are very rare. Thomson had removed a similar growth.

Cystic Tumor.—Mackenzie[3] described a case in a man of 67. The cyst was pear-shaped and attached near the anterior commissure, lying upon the left vocal band, which had been absorbed from pressure. It was removed with the forceps. The author reported a similar case in a woman of 80. There was no recurrence.

Carcinoma.—Mokes[4] reports a case, with a photograph of the patient taken 3 years after operation. The patient still wears a tracheotomy-tube, most of the time for fear of stenosis. The voice is very good in view of the fact of the existence of but one vocal band, and there is no return of disease. Lack,[5] in a very able paper, points out the danger of infection of healthy tissues during operations on malignant growths. To show the possibility of a malignant growth infecting healthy tissue in contact with it, he quotes 10 cases of carcinoma in various organs. Another series follows of 11 cases, in which the secretions of carcinomata were in various ways brought in contact with healthy tissues at a distance, with development of secondary growths. Fourteen more cases indicate clearly the danger of infection during operations, the recurrence taking place in operation-wounds rather than in the lymphatics. In operations on the larynx he condemns splitting the thyroid cartilage when the neoplasm is liable to be cut, and emphasizes the importance of removing the malignant growth entire, cutting through healthy tissues only. When cutting into the growth is unavoidable, he uses pure phenol to cauterize the field of operation.

Malignant Disease of the Larynx.—Delavan[6] says epithelioma generally arises in the ventricular band, but may begin in the vocal band, the epiglottis, or the aryepiglottic fold. An early sign is infiltration of muscles in the vicinity, resulting in impairment of motion, with hoarseness. The disease

[1] Jour. of Laryn., May, 1896.

[3] Lancet, Oct. 7, 1895.
[4] Ann. of Surg., Dec., 1895.
[5] Lancet, June 15, 1896.
[6] N. Y. Polyclinic, July 15, 1895.

extends backward. The cervical glands under the anterior border of the sternomastoid muscle are earlier involved in the extrinsic variety. Semon[1] reviews the histories of 103 cases; 79 were in men and 55 intrinsic. He notes the importance of hoarseness as the earliest symptom, and the vocal bands as the most common point of origin. He performed 3 partial extirpations of larynx, with 1 death; 4 thyrotomies with resection of cartilage, no death; 4 thyrotomies with removal of soft parts, 2 deaths; 1 subhyoid pharyngotomy, 1 death; recoveries, 58.3%.

Potassium Iodid in Doubtful Diagnosis.—Rice[2] advises the use of potassium iodid in doubtful cases of disease of the larynx, and says we might continue to cite cases of most varied pathologic appearances—ulcerations which seem to be tuberculous, small growths which were apparently benign, large swellings with every appearance of malignancy, afterward proved to be specific or, at least, disappeared through the effect of potassium iodid.

Laryngeal Tuberculosis.—Schadewald[3] reported a case with limited pulmonary tuberculosis, and 2 healed and 1 existing laryngeal ulcer which healed during treatment by rubbing **creolin** into the body vigorously. The total amount used was 7 oz. He advises incorporating lanolin with it to prevent adhesions to the linen, which would cause irritation. Bergengrün[4] reports 7 cases of tuberculous laryngitis cured by general treatment and **lactic acid** and **iodoform** locally. Newman[5] exhibited 2 cases of primary tuberculosis of the larynx cured by spraying with a solution of **iodoform** in ether following a spray of cocain. A large number of other cases in which he used the same treatment obtained notable relief. To be efficient the iodoform treatment must be adopted before ulceration takes place. Spengler[6] concludes that **parachlorphenol** applied to the larynx directly, or in 10% solution in a spray, will induce cicatrization of tuberculous ulcers and resorption of tuberculous infiltration without irritation. Dissolved in glycerol, it has a local anesthetic action lasting several hours. It also has a favorable action on lupus and may effect a cure. Whalen in a personal communication reports a most interesting and successful experience in the use of **guaiacol** applications. The patient was a male of 30, who developed incipient pulmonary tuberculosis in 1891, which yielded to 10 months' treatment with creasote and syrup of hypophosphites with maltine. A year later he contracted a severe cold, followed by return of lung-symptoms and laryngitis, for which the larynx was sprayed with solution of zinc sulphate, gr. 2 to 15 to the ounce, for 2 months. Upon the appearance of tumefaction of the arytenoids and infiltration of the ventricular bands a spray of iodin terchlorid was made daily, beginning with .25%, increasing to 1% within 2 months. On the occurrence of ulceration of the left vocal band applications of lactic acid in varying strength were made,

[1] Lancet, Dec. 15–29, 1894, quoted in Am. Med.-Surg. Bull., Sept. 1, 1895.
[2] Med. Rec., N. Y., July 6, 1895.
[3] Berl. klin. Woch., 1895, No. 24, p. 529, quoted in Am. Jour. Med. Sci., Sept., 1895.
[4] Arch. Laryn., ii. p. 2, quoted in Quart. Med. Jour., Jan., 1896.
[5] Quoted in Jour. of Laryn., Mar., 1896. [6] Quoted in Med. News, Nov. 30, 1895.

the local conditions becoming more unfavorable for 3 weeks. Then he used a spray of guaiacol in oil of sweet almonds, beginning with 20% and increasing to 50%. This was followed in a few weeks by gradual improvement, the ulceration healing completely in less than 2 months; some swelling remained for about 10 months. The lung-symptoms were arrested, and at the same time the patient's health was greatly improved. Examination in March, 1896, showed no extension of lung-disease, though the sputum contained numerous tubercle-bacilli. The larynx is normal, except partial destruction of the left vocal band, the remaining portion being redder than the opposite band. Some hoarseness remained, but during the whole period the patient had not lost a day from his business, which requires many hours of talking daily.

Surgical Treatment.—Gleitsmann[1] gave the following indications for curetting: 1. In cases of primary tuberculous affections without pulmonary complications; 2. In cases with concomitant lung-disease which is either in the incipient stage or has at least not progressed to softening and hectic conditions; 3. It is best adapted for circumscribed ulcerations, and especially infiltrations of the larynx. 4. For the dense, hard swelling of the arytenoid region, the ventricular bands, the posterior wall, for tubercular tumors and affections of the epiglottis; 5. In advanced lung-disease, with distressing dysphagia resulting from infiltration of the arytenoids, curetment is justifiable as the quickest means to give relief. Contraindications are—1. Advanced pulmonary disease and hectic; 2. Disseminated tuberculous disease of the larynx, leaving little or no healthy tissue; 3. Extensive infiltrations, producing severe stenosis when tracheotomy is indicated. It is not to be recommended in nervous, distrustful patients, who lack the necessary perseverance or confidence in their physician. Gleitsmann[2] reported 12 cases which he had curetted. Of these 3 were dead, 5 in statu quo or had lost the improvement previously gained, and 4 are without recurrence of the laryngeal disease from 6 to 10 months. He also referred to a case he had cured 7 years before with the curet, galvanocautery, and lactic acid. Krause[3] said it was important to remove all diseased tissues, and advised applications of lactic acid after operation, to promote healing. He claims that it relieves but does not cure patients. Heryng said that tubercle of the larynx may heal by itself without local treatment. Surgical operations are indicated in most recent cases. Healing of deep ulcers is effected quickest by scraping or removal of tubercular tissues. He applies a 1% or 2% solution of pyoktanin to prevent infection.

Hysteric Aphonia.—Kennel[4] states that sudden application of ethyl chlorid to the nape of the neck, thus freezing a spot the size of a shilling, never failed to relieve attacks in 2 patients. In Merrick's[5] case after 8 months of whispering a woman recovered her voice suddenly, and found it impossible to whisper thereafter, any effort to phonate resulting in distinct tone.

[4] Lancet, Jan. 18, 1896.

[5] Jour. Am. Med. Assoc., Nov. 16, 1895.

Laryngeal Paralysis.—Lubinski[1] noted 5 cases of laryngeal paralysis in typhoid fever, 4 beginning after defervescence. It is generally due to paralysis of the vocal band, though ulceration, edema, and perichondritis may be found postmortem. Lubinski[2] noted in typhoid fever 2 cases of abductor paralysis, 3 cases involving one recurrent laryngeal, and 1 involving both. He also describes a case of posterior paralysis lasting 1 month and due to influenza.

Intubation.—Dr. J. O'Dwyer[3] recommends a simple incision through the cord, which destroys the valve, followed by the wearing of a cylindric intubation-tube until the incised cord has healed in the retracted position. He recommends hard-rubber instead of metallic tubes in this condition, as the rubber tube is not subject to calcareous deposit. He states that the excision of the vocal bands in this condition is unjustifiable.

Motor Aphasia.—Thomas and Roux[4] found that by showing patients the movements of articulation they quickly acquired the faculty of pronouncing syllables, and even words, so that in long-standing cases of motor asphasia they soon recover the power of language.

Hystero-traumatic Aphonia.—Bianchi and Massei[5] report a rare case of hysterical aphonia following the extirpation of a tumor from the larynx. After the aphonia had lasted 7 months the patient was hypnotized, and while in this condition the suggestion was made to her to speak in the future in a loud voice. This treatment was successful, and until the time the report was made, 5 months, the patient had continued to speak in a loud, distinct voice.

Stammering and Stuttering.—Winckler[6] traced heredity in 18 cases. This element is a weakness in power of coordination and a weak central nervous system. Local irritations, such as nasal defects, adenoids, papillomatous degeneration of mucous membrane of the turbinated bodies, purulent rhinitis, otitis media, and general physical condition due to scrofulosis, cryptorchism, phimosis, balanitis, and onanism, are etiologic factors. A high palate and trapezoid maxilla were found in 54 of 210 cases. Children who stammer excessively often have defective hearing.

Therapy.—Coen[7] describes the early studies of Colombat de l'Isere, Klancke, Lehwess, and Rosenthal, before Adolf Kussmaul in 1877 put the therapeutics on a scientific basis. Austrian and German methods both recognize the importance of normal respiration in normal speech. Coen fathered the older Austrian school; Gutzmann, the younger German school. After respiratory defects are remedied regulation of voice and articulation-coordination are in order: 1. Lung-gymnastics; 2. Regulation of coordination of the vocal and speech-apparatus; 3. Controlling disorders of innervation and removing causes of reflex irritation; 4. Developing the power of the controlling will; 5. General toning up of the system. Stimulating and sedative

[7] Ibid., July 27, 1895, and May 2, 1896.

treatment alternate. Hydrotherapy and electricity are used when indicated to develop respiratory power. The Berlin school relies upon continual gymnastics of the muscles of the speech-apparatus, so that the patient is conscious of certain movements. He is also trained to suppress involuntary movements. Coen holds that physical and moral endeavor is essential, and believes stammering is due to lessening of normal respiratory capacity dependent on intangible anatomic disturbances in the medulla oblongata and spinalis. Schronck believes it due to disease of the cerebral cortex. Kussmaul calls it a neurosis due to congenital irritability of the syllable-coordinating apparatus.

Laryngeal Ictus.—Bedos[1] reports the cases of 41 men and 2 women, with an average age of 49. Sedentary habits, rheumatism, gout, and obesity predispose to it. "Old coughers" with chronic respiratory diseases are especially subject to it. The attack may occur at any time. The symptoms are —a tickling sensation in the larynx and sudden transient unconsciousness, with or without convulsive movements. The cough may be severe or light, the loss of consciousness complete or partial. The heart-action is weak for a moment. Convulsions are confined to upper limbs. Spasms are never tonic. The tabetic crisis is an epileptiform convulsion with true dyspnea, sometimes fatal. Tabetics may have crises simulating ictus, but other signs of tabes, pains, Romberg's sign, etc., will distinguish it. Charcot refers laryngeal ictus to reflex irritation of the superior laryngeal nerve; Gasquet, to circulatory disturbance in the semicircular canals and labyrinth; Cartaz ascribes it to hyperesthesia of the laryngeal mucous membrane causing inhibition through the pneumogastric nerve; Knight refers it to cerebral anemia.

Vibration of the Vocal Bands.—Hodgkinson[2] by insufflating finely powdered indigo on the bands and phonating, found the particles moved from the edge in curved lines corresponding to the amplitude of vibration of the bands. In normal bands the line extends from the anterior commissure to a point posterior to the vocal process with medium chest-tones; with lower tones the line extends farther posteriorly and is less curved. These results vary with quality of tone and with abnormal conditions of the bands. With falsetto tones the powder forms a line parallel to the free edge of the band, but is arrested halfway from the free edge to the ventricle, indicating that the whole length of the band vibrates with nearly equal amplitude, the outer half vibrating with less energy, a nodal line corresponding with the line of powder.

Teacher's Nodes.—Milligan[3] classifies the lesions found as follows: 1. Subacute and chronic laryngeal catarrh, affecting mainly the true vocal bands; 2. Chronic catarrhal laryngitis, with subsequent paresis of certain laryngeal muscles; 3. Chronic catarrhal laryngitis, with a varicose condition of the smaller vessels of the true band; 4. Chronic catarrhal laryngitis, with secondary pachydermic changes. He attributes the condition to the long hours of teaching, the raised pitch of voice necessitated, and the early age, 13 to 16, at which many teachers begin.

[2] Brit. Med. Jour., Aug. 24, 1895. [3] Ibid., Nov. 2, 1895.

Diseases of the Trachea.—Griffin[1] described the case of a woman of 30, with condylomata extending 1 in. along the anterior wall of the trachea from a point near the vocal bands and passing $\frac{2}{3}$ around. The growth was irregular on the surface, and separated by fissures with abrupt and sharp edges, red in color, and covered with pultaceous secretions. Dram doses of potassium iodid 4 times a day, with an ointment of the red oxid of mercury rubbed into the region of the thyroid cartilage, in 3 weeks caused complete disappearance of the growth.

Fracture of Trachea.—Briegel[2] collected 33 cases with 22 deaths. Most of them were the result of external violence, though in 2 cases coughing is given as the cause, and 3 times excessive and sudden bending of the head backward or forward. The fracture could rarely be felt, on account of great emphysema. In some cases that survived cicatricial stenosis resulted. If dyspnea is severe, the trachea should be opened at once and artificial respiration practised if necessary.

Tracheotomy and Insufflation for Asphyxia.—Thiery[3] relates a case of asphyxia, due to edema of the glottis and chloroform-anesthesia, which recovered after trachectomy, followed by direct insufflation for 10 minutes. The method should be used in all grave accidents from asphyxia, and should be persevered in, as 2 cases recovered after more than an hour's insufflations.

Medication of the Bronchus.—Muir[4] in 40 cases of phthisis, bronchiectasis, and bronchorrhea has injected remedies directly into the trachea by a $\frac{1}{2}$-oz. syringe with long laryngeal tip. Solutions of menthol from 7.5% to 15% in benzoinol were used, to which from .5% to 3% guaiacol was added in some cases. For offensive expectorations a 2% solution of europhen was used with benefit. Iodoform, benzosol, and salicylic acid cause nausea or are irritating. Injection is made after full inspiration, and causes a sensation of warmth in the chest. A solution of cocain to the larynx is advised before the first injection, which may be directed toward either bronchus. He recommends the method as a palliative in phthisis, not to replace constitutional medication.

DERMATOLOGY AND SYPHILIS.

By LOUIS A. DUHRING, M. D.,

OF PHILADELPHIA.

SUPERFICIAL ERYTHEMATA.

Multiform Erythemata.—Von Düring[1] divides the multiform erythemata into 3 groups: 1. Those in which the cutaneous manifestations are due to general infectious diseases, as in erythema exsudativum multiforme and erythema nodosum; 2. Angioneurosis, under which caption are comprised a number of urticarial and maculopapular efflorescences which bear resemblance to the cutaneous lesions of the infectious diseases, idiosyncrasy playing a part in the group; 3. Erythemata due to emboli, as exemplified in many of the so-called malignant multiform erythemata. The secondary metastases met in septic diseases also belong in this category.

The Visceral Complications of Erythema Exsudativum Multiforme.—Osler[2] defines erythema exsudativum as "a disease of unknown etiology with polymorphic skin-lesions—hyperemia, edema, and hemorrhage—arthritis occasionally, and a variable number of visceral manifestations, of which the most important are gastrointestinal crises, endocarditis, pericarditis, acute nephritis, and hemorrhage from the mucous surfaces." A noteworthy feature of the disease is the tendency to recurrences. Attention is also called to the observation that cutaneous symptoms may be absent, visceral disease alone being present; 11 cases are recorded in all of which gastrointestinal crises occurred—colic, usually with vomiting and diarrhea; 5 had acute nephritis. The lesions of the skin are polymorphic, ranging from simple purpura to extensive local edema, and from urticuria to large infiltrating hemorrhages into the skin and subcutaneous tissue. In all except 1 case there were several attacks, covering a period of from 2 months to 8 years. Hemorrhage was the most constant lesion. [The article is a valuable contribution to general pathology and to hemorrhagic disease in particular, especially purpura, of which the cases reported seem to be examples. Erythematous lesions were absent, and we therefore fail to comprehend why the cases recorded should be designated by the distinguished writer as erythema multiforme. It is a question of nomenclature and classification, and not of the observations made, that is open to criticism. The definition given of erythema multiforme seems too broad to be useful.]

Treatment of Erythema Intertrigo by Chromic Acid.—Brault[3]

[1] Arch. f. Dermat. u. Syph., Bd. xxxv. H. 2 u. 3. [2] Am. Jour. Med. Sci., Dec., 1895.
[3] Ann. de Dermat. et de Syph., No. 4, 1896.

finds that chromic acid, in the form of a 3% solution, not only produces a rapid cure, but also prevents, more effectually than any other remedy, relapses, the skin becoming somewhat hardened or tanned from its use. In cases in which there is much irritation it is advisable to employ at first some mild, moist antiseptic dressing The affected parts should be washed and dried, when the solution of chromic acid is to be brushed lightly over the skin. [It is well known that chromic acid in solution sometimes acts happily in hyperidrosis and bromidrosis in from 2 to 5% strength. A word of caution may be given: In intertrigo the solution should at first be weak, for sometimes it sets up an acute erythematous dermatitis instead of curing the disease.]

Recurrent Scarlatinoid Erythema.—Hartzell[1] reports a case, and justly remarks that, owing to the close resemblance of this cutaneous manifestation to a serious infectious disease, the question of diagnosis is of great importance. It may be distinguished from scarlatina by attention to the following points: 1. The redness is likely to be diffuse instead of punctate; 2. Instead of beginning upon the face, as in scarlatina, it usually commences upon some part of the trunk and spreads rapidly to other parts; 3. Desquamation begins much earlier than in scarlatina, usually on the second or third day of the attack; 4. Throat-symptoms are absent, or, if present, are usually very mild, and the so-called strawberry tongue is absent; 5. There are never any symptoms pointing to the kidneys, and the repeated recurrence of the eruption will make the diagnosis plain. The treatment should be on general principles. In the writer's case the internal administration of the fluid extract of jaborandi seemed to influence the disease favorably, mitigating at least the itching and burning.

Urticaria Treated with Calcium Chlorid.—Wright[2] considers the theories which seem to justify the administration of calcium chlorid in urticaria. In all conditions of diminished blood-coagulability there is not only a tendency to actual hemorrhage, but there is also a disposition to "serous hemorrhage," or an increased transudation of the fluids of the blood into the tissues. Persons whose blood-coagulability is diminished appear to be particularly liable to urticaria or to serous effusions into the skin. Instances are cited in which urticaria could be produced by diminishing the blood-coagulability by taking inordinate doses of calcium chlorid and by eating acid fruits, which diminish the blood-coagulability by abstracting lime salts from the blood. These facts show that an increased transudation may be due to a diminished blood-coagulability; hence hope may be entertained of correcting the defect of blood-coagulability. With this object in view calcium chlorid was employed in 2 cases, in doses of 30 gr. t. i. d. at first, and later in less amount (gr. 10), with the result of cure. In 1 case the blood-coagulation time was reduced in 2 days from 8 minutes to 2 minutes and 45 seconds. [One of the 2 cases reported was that of a man, aged 84, in which, although sulfonal was also used, the remedy seemed to have effected the cure. In the other case the urticaria was produced by an injection of antitoxin, and it is possible that

[1] Univ. Med. Mag., Aug., 1895.

[2] Brit. Jour. of Dermat., Mar., 1896.

the urticaria would have disappeared had the calcium chlorid not been used; but the interesting point in both cases is the count of the blood-coagulability-time after using the drug, and the rapidity—2 or 3 days—in which this occurred.]

ECZEMA AND PSORIASIS.

On an Outbreak of Perioral Eczema in the East End of London.—Savill[1] reports a large number of cases of an unknown epidemic disease of the skin, attacking chiefly the face and occurring in children. The affection has no relation with the epidemic dermatitis to which he directed attention in Nov., 1891, beyond its epidemicity and seasonal influence. In all, over 700 cases were observed, their investigation extending over a period of 18 months. In the study of the cases 3 important features were revealed: 1. The remarkable uniformity of the eruption in its appearance and locality; 2. The spread from person to person by contagion; 3. The disease was confined to children under 14 years of age. The chief clinical features were—1. The distribution around the mouth; 2. The uniformity of appearance as red, dry, scurfy patches; 3. The fairly uniform course and duration of each patch. Histologically, the disease was a catarrhal process of the epidermis. The very constant resemblance to the appearance of a dry eczema, and its equally constant distribution around the buccal and nasal orifices, induced the reporter to suggest the name "perioral eczema." The disease may be provisionally defined as a contagious malady, consisting of dry, red, scurfy, ovoid patches, each of which tends, after a few weeks, to spontaneous recovery; confined to the face and neck; rarely attacking children over 14; and occurring only during the summer months of the year. The reporter gives the differential diagnoses from eczema, seborrheic eczema, ringworm of the body, impetigo contagiosa, and the epidemic dermatitis which he described in 1891. The disease is regarded as infectious under certain conditions. Photographs accompany the paper. [The disease is peculiar, and cannot be considered as being an unusual form of any of the well-known diseases of the skin. The history and course point to an infection peculiar and due to some unknown causes connected with the institution or locality in which the epidemic occurred.]

Eczema due to Malaria Cured with Quinin.—Brocq[2] reports a case of circumscribed eczemaform eruption due to malarial poisoning occurring in a woman 40 years of age, apparently in good health, who had been under treatment for a rebellious eczema of the hand several years before. Upon the end of the nose, on the left side, was a small eruptive patch of irregular shape. The skin was red and slightly swollen; upon its surface were 7 or 8 papulo-vesicles, grayish-yellow and slightly moist. There was slight burning rather than itching, most marked in the morning upon awakening, and disappearing in the afternoon. It had lasted about a month and had spread but little. There was no other eruption elsewhere. Observation showed that the patch underwent regular variations: thus it enlarged some days before the menstrual

[1] Lancet, Jan. 4, 1896.

[2] Ann. de Dermat. et de Syph., No. 1, 1896.

period, becoming more swollen, red, and oozing. Every morning upon awakening the lesion was much inflamed, and an abundant, transparent, serous liquid oozed from the vesicles. Ordinarily it was very early in the morning when this congestive attack occurred, announced by a localized fever, with throbbing, tension, and burning. The attack reached its maximum between 7 and 9 o'clock in the morning, and then gradually diminished. By 6 o'clock in the evening the lesion was scarcely visible. Although the patient had never had an intermittent fever, she had had diverse manifestations of paludism which had yielded only to quinin in large doses. She was given quinin hydrochlorate, the local treatment being limited to a simple dressing. The effect of the quinin was remarkable: at the end of 48 hours the morning congestive attacks and oozing had ceased, and at the end of 4 days the lesion was no longer elevated and was undergoing resolution. The patient later ceased all treatment, when the eruption returned, but it again yielded to quinin. The writer concludes—1. That this disease of the skin should be placed among those dermatoses, still but little known, which constitute the pure and true cutaneous form of masked paludism; 2. That in the presence of a rebellious dermatosis, with unusual symptoms, one should think of the possibility of paludism; 3. That quinin and arsenic are in these cases really heroic remedies; 4. That the class of "paludides" proposed by Verneuil and Merklen ought to be accepted. [It is now generally conceded by dermatologists everywhere that malaria may be regarded as a recognized cause of various diseases of the skin, especially inflammatory and neurotic affections.]

Treatment of Eczema.—Bowen[1] considers at length the chief methods of treatment that have been introduced or advocated during later years. No specific has been discovered, and few new drugs have of late been added to the list of internal remedies. Arsenic is never used in the acute stage, being reserved for the chronic varieties, and even here it is employed much less than formerly. In the acute forms the inflamed surface should be protected from the outer air, the secretions absorbed and their formation limited, and remedies used to lessen the itching. Pastes are now used more often than ointments. They are composed of indifferent or astringent powders mixed with petrolatum in such proportions that a smooth, thick paste is formed. Chief among these is the paste introduced by Lassar, composed of equal parts of zinc oxid and starch in double the quantity of petrolatum. Salicylic acid is often added with advantage to this paste in the strength of 10 to 15 gr. to the ounce. The chief action of salicylic acid upon the skin is of a keratolytic character; that is, it has the property more than any other drug known of softening and dissolving the horny layer, without at the same time setting up inflammation. In the later stages of the disease, when there are considerable infiltration in the corium and hypertrophy of the horny layer, salicylic acid may be used with advantage in much greater proportion than in the formula just given. Salicylic ointments in the treatment of infantile eczema have been much extolled. Taking the paste mentioned as a base, various medicaments, such as sulphur,

[1] Boston M. and S. Jour., Oct. 10, 1895.

ichthyol, boric acid, and the like, may be advantageously incorporated with it. The writer speaks well of the salicylic soap-plaster recommended by Prof. Pick for the vesicular and moist as well as for the thickened forms of eczema. It is of special value in the latter forms, and is composed as follows: Liquefied soap-plaster, 2½ ounces; olive oil, 5 drams; salicylic acid, 22 gr. The plaster is spread, and then cut into strips which are firmly adapted to the affected parts and left in position for several days. Attention is called to ichthyol and resorcin. The efficacy of ichthyol is probably due in part to the large percentage of sulphur it contains. It may be used in solution with water in various proportions—as a thick varnish, mixed with albumin or starch, or in ointment form. On moist patches an emulsion with water of the strength of 1 : 10 or 1 : 20 parts is often of service, especially when followed by a soothing ointment or paste. Resorcin is of much value in certain cutaneous affections, but, according to the writer, it plays a small part in the treatment of eczema. "Ointment-muslins," made by impregnating muslin on one or both sides with the ointment desired, are useful in many cases. "Plaster-muslins" are also described, their usefulness being regarded far greater in tuberculosis and in chronic processes with hypertrophy of the horny layer than in eczema. Particular attention is called to the point that as yet there are no specifics for eczema, and that regulation of the diet, attention to hygiene, and removal of any conditions unfavorable to the general health are of very great importance. Internal remedies are frequently of great aid, especially in the so-called nervous forms of the disease, and success depends in this class of cases more upon the general management of the patient's life and upon moral influence and support than upon topical applications.

Protest against Over-treatment in Eczema.—Morris[1] believes that the notion is still somewhat widely prevalent that eczema is the offspring of a constitutional dyscrasia, or, in the language of the old pathology, the outward and visible sign of an inward peccant humor of some kind. This supposition (for he regards it as nothing else) leads to errors in treatment of the disease in two opposite directions: on the one hand, of doing too little; on the other, of doing too much, some believing that the skin-lesions act as issues whereby the supposed mischievous principle is withdrawn from the system, leaving them untreated in the fear that the healing of them might cause morbid determinations to the internal organs—a fear for which, according to the writer's experience, there is no foundation. Others direct all their therapeutic efforts toward forcing on what they call a "crisis." Their plan of campaign, apparently, is to drive the enemy into the open country, where he can in theory be crushed without difficulty. It is natural enough that at hydropathic institutions this method is most in favor, for there critical eruptions are among the usual incidents of the treatment, and therefore easily come to be looked upon as being an essential element in the cure. There is something seductive in the notion of bringing the disease to the surface and there dealing with it in a summary fashion, but, unfortunately, the plan does

[1] Brit. Med. Jour., Feb. 27, 1895.

not answer in practice. It is much easier to fan the flame of eczema than to subdue it. The writer has seen so many cases of eczema made worse by misdirected therapeutic measures that he thinks it is his duty, for the credit of the profession as well as in the interests of physicians, to utter a few words of warning on the subject. A case is cited in which a localized eczema had been aggravated by over-treatment until it was on the way to become general. The bread poultice used intensified the inflammatory process, and the bandages acted as vehicles for the conveyance of inoculable material to the parts to which they were bound. The dietetic restrictions helped to lower the patient's strength, without having any beneficial effect on the disease. The plan of treatment, in fact, was founded on an erroneous notion as to the nature of the disease. The use of strong remedies which cause irritation is more disastrous than the do-nothing policy of those who look upon eczema as a useful derivative. [The views of the writer are sound, and if followed by the general practitioner, who is often at a loss what to do next with his case in way of medication, injury to the patient may be avoided. As a rule, the remedies employed are too strong or are harsh, with the result that practically the eczema is aggravated instead of relieved, the aggravation often being attributed to an exacerbation of the process, when, in reality, it is the treatment that is making most of the mischief.]

Psoriasis Vulgaris in Infancy.—Riehl[1] records a case of psoriasis occurring in an infant 5½ weeks old, which, according to the mother's statement, first appeared on the 5th or 6th day after birth. The father of the child had been the subject of the same disease since he was 20 years of age. [Not many years ago it was stated by authors generally—especially those who followed the dictum of Professor Hebra—that this disease was not met with in those under 4 or 5 years of age, but the case just quoted, as well as others now found on record, shows that practically no age is exempt. As a rule, however, the disease spares infants and young children as well as the aged.]

Salicin and Salicylates in Psoriasis.—Crocker[2] believes that the use of these drugs is of much value in selected cases of this disease, especially in the variety "guttata" of extensive and recent development. They are useful, however, in all forms, except, perhaps, in old, chronic patches. Their employment must be temporarily discontinued if they give rise to gastro-intestinal disturbance or an aggravation of the disease of the skin.

Thyroid Extract in Psoriasis.—Thieberge[3] reports 11 cases treated in this way, and sums up his experience by stating that this drug is not a specific for psoriasis. It should be reserved for refractory cases in which the ordinary methods have failed. The effect should be watched very carefully. Brocq[4] states that the results obtained from this treatment in France have been most variable, and that he has seen it act favorably in only 1 instance, a very rebellious case. The injurious effects upon the economy of the drug and of

PLATE 15.

Dr. J. F. Schamberg's case of impetigo contagiosa annulata et serpiginosa.

the fresh gland are dwelt upon, as shown by the experience of many dermatologists and in his own cases.

IMPETIGO, HERPES, PEMPHIGUS, DERMATITIS HERPETIFORMIS.

Impetigo Contagiosa Annulata et Serpiginosa.—Schamberg[1] gives the case of a boy, aged 10, in which, in addition to pea-sized crusted pustules about the face, neck, arms, and back, there were in the axillæ and on the pubes large serpiginous annular pustular patches the size of a hand, with centers almost free of eruption (see Plate 15). The crusts were yellowish-brown, greasy, loosely attached, and bulky, projecting $\frac{1}{8}$ in. above the level of the skin. Large fragments of crust hung here and there from the borders, as if attached only by a thread. The skin was not reddened, except where the crusts had been removed. Microscopic examination of the crusts failed to reveal any elements of a fungous growth, but micrococci were found in the pus, mostly in groups of twos. The pus from an unruptured vesicopustule gave a similar result. The disease had existed 8 weeks, but was cured under a mercurial ointment. [The abstractor of the article had the opportunity of seeing this case, and is therefore in a position to corroborate the diagnosis and to verify the description. This disease, as the present case illustrates, is not always so acute in its course as is generally stated in books, nor is it by any means confined to the hands and face. On one occasion the abstractor met with a case, likewise in a boy aged 10, in which the lesions—typical vesicopustules and pustules—existed solely on the buttocks and posterior aspect of the thighs. They were pea-sized, for the most part discrete, and very numerous. The annular arrangement and serpiginous course of the lesions, as well as the long duration of the disease, in Dr. Schamberg's case are unusual and interesting.]

Herpes Zoster relieved by Camphor employed Internally.—Drinkwater[2] records a case of herpes zoster of unusual distribution, occupying the auricular, lower maxillary, and cervical regions. The pain was very severe. Opiates had been used without relief. Acting on the statement made by Edward Woakes in one of his works, that tobacco has a paralytic action on the superior cervical ganglion, and that the vasomotor paresis extended to the vessels supplied to the branches of the four upper cervical nerves, the dilated blood-vessels exerting pressure on the nerve-fibers, and thus causing pain and some trophic change resulting in vesicle-formation, and that if such were the case camphor internally should afford some relief, 5-minim doses of spirit of camphor on sugar were given 3 times a day. There was a remarkable improvement almost immediately. The first night she slept well, and the next day she was quite free from pain, and it never recurred at all; but what struck the reporter as most remarkable of all was that the group of vesicles that had come out last were all retrogressive, and those over the parotid had disappeared, leaving no sign of their former presence—that is, they had not gone through

[1] Jour. Cut. and Gen.-urin. Dis., May, 1896. [2] Brit. Med. Jour., Apr. 13, 1895.

the usual course of crust-formation; the contents had been reabsorbed. The reporter feels inclined to attribute the amelioration of the disease to the effect of the camphor, and would recommend its trial in other cases.

Nerve-lesions in Herpes Zoster.—Ebstein[1] reports a case of herpes zoster with facial paralysis, and another with sensory disturbances, and gives some interesting results of an investigation of the disease. Concerning the pathology, he agrees with the view of Recklinghausen, that there is a primary affection of vasomotor nerves, the vasodilators being irritated, and looks on the herpes as an intense angioneurotic disturbance which may be associated with diseases of the motor or sensory, spinal, or cerebral nerves. The rare appearance of herpes in cases of motor disturbances, and the cause of the paralytic phenomena in motor nerves and of symptoms of irritation in sensory and vasomotor nerves he thinks cannot now be explained. In most cases the disease results from causes acting on the body in general, though trauma and cold may assist. Infection or autointoxication may also possibly play a part. [In some cases there is every reason to believe that the disease is due to an infection, but the nature of this infection is often obscure or unknown.]

The Protozoa-like Bodies of Herpes Zoster.—Hartzell[2] calls attention to and describes certain peculiar organisms found in the vesicles of herpes zoster, being the same which Pfeiffer regards as protozoa and the cause of the disease. The author found these bodies not only in the ordinary forms of zoster, but also in a case of traumatic zoster in which there had been many recurrences for a period of years. He does not regard them as protozoa, but as being forms of cell-degeneration.

The So-called Protozoa of Herpes Zoster.—Gilchrist[3] has investigated the histopathology of so-called idiopathic herpes zoster in 20 cases. The sections were taken from lesions in different stages of the disease with a view to determining the nature of the so-called protozoa described by Pfeiffer, Wasiliewski, Hartzell, and others. These peculiar bodies were found in sections taken from a portion of skin which exhibited the erythematous stage preceding the formation of the vesicle. These sections show that the earliest changes consist of a serous exudation into the epidermis, with separation of the epithelial cells and the formation of the curious bodies under discussion. They appear singly or in groups, and are most numerous at the bottom and sides of the vesicle. Sometimes they are found among the epithelial cells of the hair-follicle, some of the largest groups being found here without the least evidence of any vesicular formation. While more numerous in the newly-formed vesicles, they are not entirely confined to them. They vary very much in character, but usually appear in the form of well-defined bodies with a thick outline which encloses granular contents, with the central portion more deeply stained. They are grouped in different ways—sometimes lying in an apparently coherent mass, and showing evidences of considerable pressure; some-

[1] Virch. Arch., Bd. cxxxiv. H. 3. [2] Jour. Cut. and Gen.-urin. Dis., Sept., 1894.
[3] Johns Hopkins Hosp. Rep., vol. i.

times the individual bodies are separated one from another, and the groups surrounded by a protoplasm; at other times the latter is absent. The masses consist of an odd as often as an even number of the bodies. Perhaps the most satisfactory idea of the origin and nature of these bodies can be formed by the study of them in the prevesicular stage of the disease and when they occur in epithelium situated at some distance from the vesicle. The bodies resemble normal nuclei in every respect, being similar to them in size, shape, staining properties, and in the possession of a limiting membrane and of a nucleolus. A careful comparison between these bodies and undoubted protozoa shows that the former can hardly be mistaken for protozoan organisms. There was no evidence of any ameboid movements in any of them. The results of the observation lead to the conclusion that these so-called protozoa are really nuclei of epithelial cells, but, even if this be granted, it has not as yet been clearly explained how these groups of nuclei arise. A number of other kinds of bodies were seen which presented some similarity to the so-called cancer-parasites. These were chiefly found in the hair-follicles and amongst the innermost layer of cells. It would seem almost certain that these bodies are only large eleidin-granules corresponding to the eleidin-granule of the stratum granulosum. They are perfectly homogeneous, well defined, stain deeply, particularly with fuchsin, and their appearance under the microscope is very like some of the bodies which are regarded by some observers as "cancer-parasites."

Acute Pemphigus.—Pernet and Bulloch[1] record 17 cases of acute pemphigus, and from their observations state that there exists a group of rare cases, accompanied by severe systemic symptoms, which affect butchers and generally end fatally. The disease follows a wound of the hand, and is probably due to a microorganism. The same etiological factors probably produce another group of very similar cases in which the subjects come in contact with animals or dead portions of animals.

Whipham[2] records 2 cases of acute pemphigus that were under observation at St. George's Hospital. Both were of unusual severity; one recovered, the other died. Both were treated by increasing doses of arsenic, and in both the remarkable effects of the drug in this particular disease were strikingly illustrated. The contribution to the literature of pemphigus is also a valuable one in many respects. The account of the bacteriologic examination of the cases is complete, and adds considerably to our knowledge. The following points were established bacteriologically: 1. A diplococcus answering in every respect to that found by Demmé, Claessen, and Bulloch was demonstrated in the contents of the bullæ of the child during life: 2. This diplococcus was grown from the contents of the bullæ, and was obtained as a pure culture outside of the body; 3. After the death of the child a similar organism was found in the lungs and minute hemorrhages were found in the alveoli; 4. Pure cultures of diplococcus, after having been grown for many generations outside of the body, when introduced into the system of either guinea-pigs or mice by hypodermic injection or "vaccination" caused death; 5. After death diplococci were grown

[1] Brit. Jour. of Dermat., May and June, 1896.

[2] Lancet, May 2, 1896.

as pure cultures from the blood of these animals, and these cultures killed other animals; 6. Appearances found in the lungs of these animals were comparable to those found in the child's lungs; 7. Diplococci were found in sections of the lungs of the animals. The following conclusions may be drawn: Since bullæ have not been produced in the animals, it cannot be said that the diplococci found were the cause of the disease; but, as this organism was found by 4 independent observers in cases of acute pemphigus, we think, in the light of the result obtained by the reporter, that there is a strong presumption in favor of this being the case. The treatment by arsenic was adopted in both cases, and the improvement in either case followed immediately upon its administration. A change for the better occurred in the case of the woman within 48 hours of her taking the first dose of arsenic. In the case of the child the formation of the bullæ was very greatly checked in about the same time. [The great value of arsenic in true pemphigus is not as fully appreciated as it deserves. Much credit is due Mr. Hutchinson for the many observations he has published during the past 30 years illustrative of the favorable influence of this drug in most cases of the disease. True pemphigus is much rarer in this country than it is in Europe, not many instances being recorded in the United States.]

A New Suppurative and Pemphigoid Eruption of Cutaneous Tuberculosis.—Hallopeau[1] reports a case of this very rare form of disease, the substance of which may be formulated as follows: 1. Pustular tuberculosis in young subjects may be the point of departure of deep infiltrations into the derma, which extend themselves rapidly on the surface in such a manner as soon to form indurated patches several centimeters in diameter, rounded or ovoidal, often confluent, ulcerated or only partially so, having a tendency to heal rapidly; 2. The epidermis about the periphery of the patches may be the seat of a pemphigoid formation; 3. The characters of this neoplasm are to be distinguished from all other forms of cutaneous tuberculosis heretofore described; they may coincide with the tuberculous infiltrations in agminated nodules and with the elements of lichen scrofulosorum, and may be centered around the hair-follicles.

Pathologic Anatomy of Duhring's Disease (Dermatitis Herpetiformis).—Leredde and Perrin[2] describe in the variety known as "herpes gestationis" and in the commoner form of the disease the following histological changes: The lesions of the derma are often limited to the papillary bodies, or at least are most abundant there. Diapedesis is sometimes very intense. The migratory elements consist essentially of lymphocytes and eosinophilous cells. Cells of a different kind, polynuclear elements, are observed when the blebs and vesicles have matured, but more abundantly when they have suppurated. This occurrence is probably due to ordinary microbic infection. Edema is the second essential element of the alterations of the derma; it is at times excessive, and is the result of a vasomotor paralysis of the vessels of the derma. The existence of migratory eosinophilous cells between the

[1] Jour. des Mal. cut. et syph., Fév., 1896. [2] Ann. de Dermat. et de Syph., 1895, p. 451.

cells of the mucous layer is altogether peculiar, marks the importance of these elements in the disease, and shows the tendency of the skin to eliminate them in all possible ways. The diffuse elimination of these elements by the epidermis is only accessory, the vesicles and blebs being the essential means of excretion. The writers believe that the erythema, vesicles, and blebs, grouped in diverse ways, are the morbid elements which reveal to the clinician a general malady, the cutaneous effects of a sanguineous alteration. This alteration, constant in the cases which they have studied, determines the elimination by the skin of eosinophilous cells in excess in the blood. The identity of herpes gestationis and dermatitis herpetiformis (long ago insisted upon by Duhring) is found both in the presence of cells having a special microchemic reaction, coming from the blood-vessels of the derma and eliminated by the epidermis, and by the alteration of the blood, in which one finds a certain number of eosinophilous cells.

The Dermatosis of Duhring occurring in Pregnancy.—Perrin,[1] who has made a study of this disease (also known as "herpes gestationis"), arrives at the following conclusions: 1. Herpes gestationis is a variety of Duhring's disease. Pregnancy predisposes to it because of the troubles it causes in the functions of the kidneys. 2. Duhring's disease seems to be connected with the presence in the blood, afterward in the skin, of a substance which is fixed by the white globules under the form of acidophilous granules. 3. The toxicity of the liquid in the vesicles appears to be due to this substance. It is this which produces the nervous effects of the disease, and perhaps the death of the fetus in pregnant women who are affected by it.

Dermatitis Herpetiformis in Concentric Circles.—Hallopeau[2] describes a rare variety of this disease, different forms manifesting themselves in the course of its evolution. At first it was composed either of vesicles or groups of vesicles situated upon an erythematous base; or of papules, the central portion of which soon became the seat of a bleb or of blebs, which dried up, the desiccated epidermis of which soon assumed a dark-red tinge. Soon the erythema spread eccentrically, and a circle of vesicles, isolated or confluent, was seen at its periphery. The eruption continued to spread; a series of new rings, alternately erythematous and vesicular, varying in number from 1 to 6, formed in succession. On a certain number of the papules vesication forms, not in the center, but at the periphery, in the form of a collarette. If two patches coalesced, the parts which formed the two circles (*i. e.* where they met) were partially obliterated. The color of the erythema was bright, dark, or pale red according to the duration of the lesion. The contents of the vesicles were serous at first, sometimes becoming seropurulent. In various situations over the trunk the patches tended to run together, and thus to form large

[1] "Dermatose de Duhring au Cours de la Grossesse," Ann. de Dermat. et de Syph., 1895, p. 936.

[2] Pictorial Atlas of Skin Diseases and Syphilitic Affections, in photolithochromes from models in the Museum of the St. Louis Hospital, Paris, London, and Philadelphia, Part 3, 1896.

erythematous tracts surrounded by a regularly polycyclic, circinate, bullous, raised margin. In the differential diagnosis the analogy and resemblance to herpes iris is pointed out by the writer, but he and his colleagues concluded that the diagnosis of dermatitis herpetiformis was more accurate. Subsequently a purpuric eruption supervened, superadded to which symptoms indicating the occurrence of an acute nephritis set in. At the same time, the general health seriously deteriorated, and the patient died within a month. Hallopeau thinks that the mode of progression in concentric circles of this erythematovesicular eruption can scarcely be explained otherwise than by the centrifugal development of some infectious agent, probably of a toxin; for the tendency to attribute Duhring's disease to the intervention of these products, he states, is becoming more and more marked. In all probability the fatal nephritis must be referred to the same cause.

Pathology of Dermatitis Herpetiformis (Duhring).—Gilchrist[1] examined an excised portion of skin from a typical vesicular and erythematous patch taken from the back of a man aged 22. The vesicles were minute and the patch was of a dull-red color. The sections showed the various changes from the beginning of the process up to the point of vesiculation. The epidermis remained passive, except that in the mucous layer there were a number of vacuolated cells with shrunken nuclei and a few polynuclear leukocytes. The granular layer was still discernible, and nuclear figures were not more numerous than normal. The most striking changes were found in the upper part of the corium, particularly in the papillæ. The dilated blood-vessels contained, besides red blood-corpuscles, numerous polynuclear leukocytes, and in the larger vessels a few eosinophilous cells. The next stage showed the papillæ and tissue around the vessels infiltrated with large numbers of polynuclear leukocytes, small mononuclear cells and eosinophilous cells, together with fibrin. In the more advanced processes the papillæ were filled with dense masses of polynuclear leukocytes which pushed up the epidermis, beneath which there was a clear space which contained fine strands of fibrin and granules of coagulated albumin. These dense collections of cells in neighboring papillæ became confluent in places, and with increasing serous exudation formed larger and larger vesicles, which were thus situated between the epidermis and corium. These vesicles were filled with a very close fine and coarse network of fibrin, which contained in its meshes numerous polynuclear leukocytes, some of which were disintegrated, a very few detached epithelial cells, a few mononuclear cells, a large number of eosinophilous cells, and lastly a finely granular substance (coagulated albumin). The whole upper half of the corium was also invaded by the same inflammatory material, but the mononuclear cells and the eosinophilous cells were principally aggregated around the vessels. The deeper portion of the corium did not show any change. The pathology of dermatitis herpetiformis is thus seen to be characterized in its earlier stage by a very acute inflammation of the papillary layer of the corium, with the formation of vesicles directly beneath the epidermis, the wandering out of enormous numbers

[1] Johns Hopkins Hosp. Rep., vol. i.

of polynuclear leukocytes, and also numerous eosinophiles, the epidermis being only passively engaged.

DERMATITIS.

Dermatitis Exfoliativa Neonatorum.—Morton[1] describes a case similar to those described by von Rittershain. The mother of the infant was a healthy Irish woman, and the child weighed 8 lb. at birth; 4 weeks later an erythematous eruption on the skin appeared, first on the face, and 2 days afterward the entire body was bright red. In about a week the epidermis began to crack and to scale off, and continued to desquamate for 3 weeks. When the entire horny layer had desquamated the surface of the skin remained smooth and red for a few days, and then desquamated again, this process recurring 3 times. The palms, soles, and nails were never involved. The child was well nourished and was not notably restless. The child recovered. [This disease is rare, and has not often been met in this country. In 1868, von Rittershain of Prag first encountered it, and in 1878 reported a number of cases that had been encountered in the foundling asylum during the previous 10 years, nearly half of the entire number having terminated fatally. The infants were generally attacked in the second week of life. The etiology of the disease has always been regarded as obscure, but von Rittershain thought that septic infection through the buccal mucous membrane was possible.

Another case of the same disease is recorded by White.[2] It began 10 days after birth, and seems to have been caused by an escape of hard-coal gas in the room, the mother and child both suffering considerable constitutional disturbance. The epidermis peeled off in flakes the size of a large postage-stamp. The pulse and temperature were but little affected, and the general condition remained fairly good. Recovery under simple local remedies occurred in 14 days.

Histologic Examination of the Action of Phenol on Healthy Skin.—Frickenhaus[3] concludes, as the result of many experiments made upon human beings and rabbits, that liquefied phenol as a caustic does not act very deeply, and that it is characterized by prompt scarring, especially upon hairy regions. Upon human skin it acts only upon the epidermis, but upon rabbits a portion of the cutis is affected. This effect on human skin is produced usually by one application, and surely by three, one being made each day. A necrobic eschar results, which in structure is well preserved, resembling that of dry gangrene and mummification. The necrosis is deeper in the central portion than around the periphery of the cauterization. A nonpigmented or a not deeply pigmented scar remains, which in the course of 3 months disappears entirely.

The indications in practice for the use of phenol as a caustic are plain. It should not be employed for processes which run their course in the cutis unless the horny layer of the epidermis is first destroyed by caustic potassa or am-

[1] N. Y. Med. Jour., June 8, 1895. [2] Jour. Cut. and Gen.-urin. Dis., Aug., 1895.
[3] Monatsh. f. prakt. Dermat., Bd. xxii. No. 7.

monia. On account of liability to general intoxication larger areas than from a half to a whole dollar in size should not be acted upon at one sitting. The healing should not be left to nature when a cosmetic result is desired, as on the face a certain degree of healing by second intention gives better results.

Contribution to the Pathology of Freezing.—Hodara[1] examined 5 cases of skin from 2 patients whose extremities had been frostbitten. Since the date of Recklinghausen's discovery of hyaline vessel-thrombi in gangrenous frostbite of the extremities, interest in the pathology of this disease has been awakened and his observation confirmed, especially by Kriege. Hodara believes, with Kriege and Samuel, that inflammation necessarily precedes freezing, and agrees with Unna that the regressive changes are the most important of all in the process, and sums up his investigations as follows: Freezing consists in a marked inflammatory reaction, with varied alterations of the blood and with the formation of several kinds of thrombi in most of the vessels; these thrombi are hyaline, leucocytic, fibrinous, erythrocytic, and fibrous. It is very likely that these thrombi constitute the chief cause of mortification, the homogenization of the connective tissue, and the formation of superficial and deep-seated eschars. In severe cases the eschars may extend to a considerable death; in milder cases they are cast off completely and are replaced by scars. [A series of colored microscopic drawings shows the chief points in the pathologic anatomy of the disease, made plain by the newer methods of staining as employed by Unna.]

Hydroa Æstivale.—Graham[2] gives notes of 2 cases of this rare affection. The first was a girl aged 6, who 2 years before first showed some small red spots on the face and hands. They grew larger, became vesicular and then pustular, attained their full size in 2 or 3 days, when a dark spot appeared in the center of each, after which a crust formed over the whole surface. These dried up and fell off in a few days. The whole duration of each crop of vesicles was about 10 days. During the summer appeared successive crops of this eruption, which in many instances left permanent scars. In every instance the attack followed exposure to either the direct or the reflected rays of the sun. In the autumn of the first year the eruption disappeared altogether, but in the latter part of the following winter, after driving on a bright day when snow was on the ground, her face was again affected, especially on parts not protected by a hood. While wearing gloves the hands were not affected, but became so when she left them off. With the appearance of the eruption there was slight burning, but it was not itchy at any time. It always appeared when she went out if the sun was shining, and sometimes after sitting at an open window if a warm wind was blowing, although the sun's rays did not shine directly on her. No effect was produced by going out on a dark, cloudy day. Nearly every form of application seemed to aggravate the disease. During the next winter, when she remained constantly in the house, small spots appeared occasionally, but they did not become vesicular and

[1] Monatsh. f. prakt. Dermat., Bd. xxii. No. 9.

[2] Jour. Cut. and Gen.-urin. Dis., Feb., 1896.

PLATE 16.

Dr. Herbert Stowers' case of dermatitis repens (Brit. Jour. Dermat., Jan., 1896).

soon faded away. The eruption occupied the face, ears, and right hand, and consisted of lesions about the size of a dime. Some were umbilicated and resembled small-pox pustules; others were covered with crusts, while very superficial scars were found in places where crusts had previously existed. The lips were much swollen and were covered with large pustules, which were elongated. There was general swelling of the face. The patient was lost sight of for 15 years, when it was learned that the condition of the skin remained the same until her thirteenth year, when menstruation commenced. From that time until the eighteenth year the eruption gradually disappeared, and at the latter age it ceased entirely, her general health being remarkably good. The second case was a woman aged 25, a blonde, the peculiar disease of the skin having manifested itself at the age of 11, and it had steadily continued since that time. The phenomena during the last 14 years have changed very little. When she was exposed to the sun's rays for about 20 minutes she noticed a burning sensation upon the unprotected parts of the body, soon followed by extreme swelling and small water-blisters. These in 2 or 3 days became yellow, and on the surface thin scales would form which would speedily dry up and fall off, leaving a reddened surface which would soon return to the normal condition. The pustules were never umbilicated. They appeared in crops, and varied in duration according to the severity of the attack, sometimes 8 or 10 days, in other cases 2 or 3 weeks. Sometimes the eyes were almost closed, and attacks were accompanied by general malaise, coryza, sleeplessness, and anorexia. The eruption occurred on any part of the body exposed to the sun, even if the latter was not shining directly on the skin. She is afraid to go out of the house even on a cloudy day, and has been kept almost a prisoner in the house during the daytime for the last 14 years.

It is evident from the description of these cases, as well as from those given by Unna, that the eruption is not always of a "vacciniform" character, and that therefore the term "hydroa vacciniforme" does not apply to all cases. The term "hydroa puerorum," adopted by Unna, is also inappropriate, as one instance occurred in a girl. The direct rays of the sun are not the only cause of the disease, as it may arise from the heated atmosphere of a room when the sun is shining. The heat from a stove, however, had no effect in either case. One of the reporter's cases knew by experience exactly how near she could sit to an open window with safety, and, moreover, there was much greater danger when the window was open than when it was closed. There was no evidence in either case that cold winds in winter would produce the eruption. [These cases have been quoted at length because the disease is rare and not well understood. The clinical features vary considerably in different cases, as the writer has demonstrated, and the diagnosis made from the lesions alone may not be easy. It is only within the past few years that it has been fully described.]

Dermatitis Repens.—Stowers[1] reports a striking case of this rare disease (see Plate 16). The patient was a woman 67 years of age, in average general health. When 30 years of age, 2 weeks after the birth of her second child, a

[1] Brit. Jour. of Dermat., Jan., 1896.

small "gathering" was noticed in the matrix of the right thumb-nail, which was incised, the nail shortly afterward being cast off. The wound never healed, but continued inflamed, and small pustules formed around it at various times. A year later the left thumb became affected in a like manner. At intervals varying from 8 to 16 months the nails of other fingers became involved, the third and fourth fingers of the left hand alone escaping. The nails of the toes were likewise affected, all being lost except the nail of the third toe of the left foot. The inflammation slowly spread to other parts of the hands and feet, which became covered with dry scales; the second and third phalanges of the fingers, the palms of the hands, the toes and soles of the feet became raw and shiny, and entirely denuded of epithelium. Tingling, itching, and burning accompanied the disease, which were severe enough to interfere with the patient's sleep. This condition of the fingers and toes persisted until the patient's death, at the age of 74, from a gastric disease, probably carcinoma. [The drawing in color presented shows a peculiar and very rare form of dermatitis, somewhat resembling eczema, and also certain rare forms of erythematous dermatitis neuropathica, usually occurring in one or more extremities, and which are sometimes reflex, attacking first one and then the other extremity, as occurred in a case of "dermatitis vesiculosa neuropathica" reported by the abstractor in the International Medical Magazine, March, 1892.]

A New Pernicious Skin-disease.—Spiegler[1] reports the case of a man aged 38 years, with a negative family history, who 18 years before had had syphilis, for which he was treated, without subsequent symptoms. The present disease began 18 days before in the form of a red spot and nodule on the breast. The rest of the body became covered with erythematous and nodular efflorescences, and soon blebs formed, some being hemorrhagic. The entire trunk and extremities showed the disease of the skin. The lesions varied in size from a pinhead to that of a hazelnut. Some simulated macular herpes tonsurans. The nodules were red and hard, and became pale on pressure. As the older macular lesions disappeared, they became covered with crusts which on removal caused slight bleeding. In other areas there were flat, dry, dark scales suggesting necrosis. The tongue was covered with a thick white coating, and on the upper surface were countless oval spots devoid of epithelium. The patient became much prostrated, and died 36 days after the onset of the disease. The blebs showed the presence of microorganisms, which were found invariably in the bleb-contents in pure culture 4 days before death, but later they were replaced by the staphylococcus pyogenes aureus, the fluid taken on the last day showing the latter microorganism only. Nothing was found in the blood except a mild degree of leukocytosis. The urine showed only a trace of albumin. A section of the skin in the region of the bleb showed the papillary vessels dilated, with small, round cell-infiltration in the neighboring layers and in the meshwork of the cutis. Fresh extravasations of blood were found in the papillæ. The cells of the mucous layer were separated from one another, the prickle-cells being extremely distinct. Kaposi suggested the name

[1] Arch. f. Dermat. u. Syph., Bd. xxxiii. p. 69.

"erythema papulo-vesico-bullosum et necroticans," both he and the reporter regarding the case as unique from every standpoint.

SPECIFIC INFLAMMATIONS.

Erysipelas in its Etiologic Relation to a Preceding Skin-lesion and its Local Treatment.—Allen[1] states that in 100 cases of erysipelas 50 were found to be due to a preexisting skin-lesion, often, it need not be stated, slight. The treatment advocated is the combination of the compressive and protective, in the form of application of bands of rubber adhesive plaster and covering the enclosed parts with ichthyol in collodion, in strength varying from 10 to 50%. The results were satisfactory.

Diphtheria of the Skin.—Müller[2] records the case of a child whose whole left side was scalded with boiling water. Under treatment, on the 7th day the wounds were covered with new epidermis. The mother now kissed the child's neck at the border of the granulating wound, and on the following day was seized with pain in the throat, and later diphtheric inflammation of the tonsils appeared. She and the aunt of the child, who was also attacked by the same disease, were isolated, and the child's father fell ill the next day, and had a slight sore throat, which was probably diphtheric. The two women recovered under injections of Behring's antitoxin ; 7 days from the date of the scald the spot where the child had been kissed was the seat of a white swollen spot 4 cm. in diameter, bordered by intensely red streaks and surrounded by an edematous area which soon spread to the right eye. Under 2 injections of antitoxin the diphtheria of the skin healed, no throat-symptoms appearing.

The So-called Parasites of Varicella.—Gilchrist[3] examined microscopically a number of the more recently formed vesicles excised from 2 cases of varicella. Numerous multinuclear cells were encountered similar to those met with in the vesicles of herpes zoster. They were found near the base and along the sides of the vesicles. Many varieties of these cells were found containing from 2 to 10 bodies (nuclei), which were apparently enclosed in a capsule, although there was some resemblance between these multinucleated cells of varicella and certain of the sporulation forms of Gilchrist's protozoa, yet the similarity extended only to these particular forms, and a comparison between these bodies and the protozoa and the blastomycetes before mentioned [elsewhere described in this book] shows conclusively that they have nothing in common with the parasites. The vesicle of varicella, speaking generally, is very similar to that of herpes zoster, except that the latter shows evidences of a more acute process. It is probable that the bodies which have been called parasites in varicella, like those of herpes zoster, are simply the results of degenerative changes in the epithelial cells.

Unusual Appearance of a Circinate Ringworm.—Cantrell[4] gives the case of a girl, aged 10, in which the lesions were situated upon the right

[1] Med. Rec., Nov. 15, 1895, p. 723.
[2] Berl. klin. Woch., Oct. 28, 1895.
[3] Johns Hopkins Hosp. Rep., vol. i.
[4] Med. News, Sept. 21, 1895.

forearm, below the elbow on the flexor surface, in the form of two rings. The outer or larger ring of the eruption was round and ¾ in. in diameter, with a number of vesicles around its border. Within this ring occurred 5 smaller, likewise ringed, vesicular lesions, which, although separated one from another, were close together (see Fig. 162). The older annular lesion was of 2 weeks' duration; the smaller ones within the ring were 2 days old. Mycelium was abundant, but spores were almost entirely absent. The same observer [1] has recently noted a similar case in which the tinea circinata was made up of two distinct rings concentrically arranged. [Such manifestations in tinea trichophytina circinata, while well known and have been depicted in literature, are nevertheless rare, and are liable to be confounded with herpes iris, a variety of erythema multiforme.]

FIG. 162.—Circinate ringworm (Med. News, Sept. 21, 1895).

Treatment of Trichophytosis (Ringworm) based on the Physiology of the Trichophyton.—Roberts' [2] conclusions, arrived at after careful study of the subject with experimentation, are—1. There exists in the vegetable world a class of minute flowerless plants (fungi) capable of digesting and assimilating hair and other keratogenous tissues; 2. The process might be called "trichophytosis," of which there are divers varieties; 3. This process might take place on the skin of the living host or in the hair that had had no connection with a living organism; 4. It follows that trichophytosis follicularis is a combination of a saprogenic destruction of an inert body which leads to pathologic cell-processes; 5. Once the fungus has entered into the interior of the follicle, any further direct control over it is lost; 6. Therapeutic influence over the fungus lies in the power of exciting proliferation of the soft cells of the follicles; 7. In any case it is desirable to carry the excitement beyond physiologic bounds, so as to produce pus; 8. Epithelial pus-formation is not followed by any loss of tissue, but connective-tissue pus leads invariably to ulceration; 9. If possible, therefore, suppuration should be limited to the epithelium.

Common Salt for the Treatment of Ringworm.—Reilly [3] having noticed the fact that children suffering from ringworm of the scalp speedily improved if sent to the seashore, treated 3 successive cases by the application of common salt to the scalp, and describes the result in each case as remarkable, a cure being effected in less than 4 weeks. A strong solution of sodium chlorid was applied to the scalp for 5 successive nights, and washed off in the morning with a solution of boric acid.

[3] Ibid., Nov. 23, 1895.

Balsam of Peru in Scabies.—Jullien and Descouleurs[1] believe that balsam of Peru is more speedily fatal to the sarcoptes scabiei than sulphur. Being volatile, it readily penetrates the burrows of the mite without the amount of friction that sulphur requires. In chronic cases it may be applied for a considerable period without giving rise to irritation of the skin, and hence is of special value in cases where pustules are abundant; in eczematous subjects; in cases in which baths might be injurious; in subjects with albuminuria; and in feeble persons. A thin coating of the drug may be lightly brushed over the skin, and afterward gently rubbed into it. It is a simple remedy; is effective and sure in its action; is always indicated, and possesses the advantage of having an agreeable odor. [The drug has long been favorably known for its power and favorable action in scabies, and is much used, especially for infants and children, in many clinics, but, as it is usually combined with sulphur, the communication of the authors is specially valuable.]

BRIGHT'S DISEASE; DIABETES.

Affections of the Skin occurring in the Course of Bright's Disease.—Pye-Smith[2] first calls attention to the only cutaneous disorder hitherto generally recognized as occurring in Bright's disease—namely, the erythema læve of Willan, the original description of which was published in 1808. He noted its uniformly smooth and shiny surface, the red patches becoming confluent, and its association with anasarca. There are, however, according to Pye-Smith, other forms of dermatitis which not infrequently occur in the course of chronic Bright's disease: 1. There is a bright-red diffused rash which appears chiefly on the trunk, less extensively on the neck, arms, and thighs, and very seldom on the face, hands, or feet. It is distinguished from the somewhat similar rash produced by natural or artificial diaphoresis by its locality, by the absence of sudamina, and by its appearing when no hot-air baths or other means have been used to produce sweating, and when the skin is harsh and dry. It does not, as a rule, either itch or smart, and only lasts a few days. It occurs oftenest in cases of chronic tubal nephritis. 2. There is a papular eruption with large, discrete, rather dark-red lesions seated on a dry, rough, and sometimes scaly surface. It occurs most often on the outer side of the thighs and legs, the shoulders, hands, and extensor surface of the forearm, but it may also affect the loins and the abdomen. It is not met with on the face or on the hands and feet. 3. Apart from the mere coincidence of eczema with Bright's disease, there is observed in some cases a moist dermatitis resembling eczema, but occupying the arms or the legs without affecting the flexures of the joints, the face, or the ears, without the irritation commonly present, and without having previously existed. 4. On two occasions the writer has seen a very extensive and profuse dermatitis closely resembling the universal exfoliative dermatitis of Wilson, very red, very scaly, occupying the scalp, palms, soles, and genitals, as well as the trunk, face, and limbs. It has come on after the symptoms of Bright's disease have appeared in cases of

[1] Ann. de Dermat. et de Syph., No. 4, 1896. [2] Brit. Med. Jour., Nov. 13, 1895.

chronic interstitial nephritis, with little dropsy, and cardio-vascular changes already apparent.

Different as these forms of dermatitis are in their anatomy, they have certain common characters apart from their occurring in patients suffering from Bright's disease. They are superficial and leave no trace behind when they disappear or after death. They run an acute or subacute, not a chronic, course, and seldom recur after they have disappeared. They are never pustular. They are occasionally purpuric, but this is rare, offering a contrast with the hemorrhagic erythema of rheumatism and erythema nodosum. The subjective symptoms are usually slight. With respect to prognosis, they usually occur in the later stages of the renal disease, and therefore may be not infrequently present at the time of death. But they often disappear long before this, and their appearance does not coincide with any special aggravation of the other symptoms. As to their pathology, the writer is not inclined to connect them with uremia except by a natural coincidence, for the latter condition is frequently noted in its most characteristic and fatal form without any cutaneous eruption. Lead carbonate, zinc oxid, calamine, or bismuth lotions have appeared to be the most useful applications, and sometimes inunction with olive oil or vaselin has been more efficient than any more active treatment. None of the affections described, except erythema læve, are common.

Uremic Bullous Dermatitis.—Barrs[1] relates a marked case of this cutaneous manifestation occurring in a woman aged 19, the subject of chronic Bright's disease. The bullæ first appeared about the vulva, and afterward invaded almost the entire surface. Uremic symptoms became more and more pronounced, and the patient died.

The Cutaneous Manifestations of Diabetes.—Morrow[2] observes that the phenomena of diabetes are essentially those of disordered nutrition. The skin is specially susceptible to impaired nutrition from this cause, under which it is particularly prone to inflammation, suppuration, and gangrene. Almost every form and degree of inflammation, from a simple erythema to the highest grade of dermatitis, may occur in the course of diabetes. The subject may be divided into two classes, the first containing affections with certain special characters which reveal their diabetic origin and nature, some being functional, others structural, such as pruritus, erythema, eczema, balanoposthitis, phimosis, furuncle, carbuncle, gangrene, and xanthema diabeticorum. In the second class may be placed affections which occur incidentally and with comparative infrequency, their tendency to recovery or retrogression according to the fluctuation in the amount of sugar present plainly indicating some etiologic connection. Among the most important may be mentioned acne cacheticorum, chronic papular urticaria, impetiginous and lichenoid eruptions, psoriasis, dermatitis herpetiformis, herpes zoster, ulcus perforans, erysipelas, and dermatitis diabetica papillomatosa. The diabetic dermatoses are important from a diagnostic standpoint. The most characteristic of the cutaneous disorders are found in the genital region, arising from contact with the saccharine

[1] Brit. Jour. of Dermat., Jan., 1896.

[2] Med. Rec., Apr. 11, 1896.

urine. The urine undergoing rapid fermentation favors cryptogamic vegetation, which appears as white deposits on the surface or between the epithelial cells. They are formed of rounded or oval cells and a mycelium made up of long and short branches, sometimes articulated. In addition to the saccharomyces are possible forms of spores; among the micrococci, the staphylococcus aureus and bacilli of the group of the bacillus coli are present. Among the most frequent manifestations are furuncles, eczema, gangrene, and xanthoma. It has been estimated that furuncles occur in from one-tenth to one-fourth of all cases of diabetes. The cutaneous tissues in diabetes are particularly prone to take on gangrene, the process occurring spontaneously or secondarily to wounds and contusions, particularly on the lower extremities.

Xanthoma diabeticorum is a peculiar disease. Out of the 21 cases reported, glycosuria was traced as the etiologic factor in all but 3. The eruption consists of small pea-sized tumors of a rounded or conical form, discrete or confluent, some of them surrounded by a yellowish summit which causes them to resemble pustules. The affection is differentiated from common xanthoma by the rapidity of its development, the character of the papules, which are firm, hard, and inflammatory, and their seats of predilection, sparing the eyelids; by its invariable presence in the form of circumscribed papules, never occurring in striæ or plaques; by its subjective sensations; by the facility of its retrogression, which may be spontaneous or the result of the removal of the glycosuria. Morrow brings forward references to various other diseases of the skin in which it has been shown that diabetes may be the cause in some cases. [The article is an important contribution to the possible etiology of certain diseases of the skin, and illustrates in a striking manner the numerous and varied manifestations upon the skin that may be produced by a single poisonous substance in the circulation.]

NOTES ON DERMATITIS MEDICAMENTOSA (DRUG ERUPTIONS).

Fordyce[1] reports several rare cases, the first being the **nodular form of iodic eruption.** The patient was a woman, aged 37, suffering from syphilitic hemiplegia. While taking 60 gr. of potassium iodid, t. i. d., two painful indurated nodules appeared in the subcutaneous tissue of the paralyzed thigh. Under the continued use of the iodid they increased rapidly in size, until they became larger than a man's fist, extending deeply into the subcutaneous tissue, involving a surface area of 5 in. in diameter. The swellings became softer and simulated deep-seated abscesses. The drug was discontinued, and in a week they completely disappeared.

Two cases of **rupia-like eruptions due to potassium iodid** are recorded, which could scarcely be distinguished from the syphilodermata which were present at the same time. The use of all antisyphilitic treatment was discontinued, and the sores were treated by boric-acid ointment, under which they healed rapidly, leaving brownish-red pigmented scars, which could not be

[1] Jour. Cut. and Gen.-urin. Dis., Dec., 1895.

distinguished from the scars left by the former syphiloderm. After a period of several weeks the iodid alone was given, and with a similar result.

An instance of **erythema scarlatinoides following the application of mercurial ointment to the pubic region** is reported, in which the diagnosis of scarlatina had been made by a physician. The diagnosis was made by noting that the pubic region was stained by mercurial inunction, which the patient admitted having used a few days before for pediculi. Within a week there followed abundant desquamation from the entire body, especially profuse on the hands and feet. At no time was there an elevation of temperature nor was the throat implicated. [Similar eruptions are occasionally observed from the internal administration of mercury, the protiodid, calomel, from the hypodermic use of calomel, from mercuric-chlorid dressings, and from exposure to mercurial fumigation, cases of which have been reported by Fournier, Engleman, Lesser, and others.]

An example of **erythematous eruption from the internal use of boric acid** may also be noted, the patient, a woman, having taken doses of 30 gr. daily for a month for cystitis. At the end of this period a polymorphous erythema appeared over the trunk, and at the same time a marked painful swelling of the upper eyelids. The eruption spread over the upper extremities, and the eyelids became indurated and hard. The boric acid was now discontinued, and cold compresses were applied to the lids. Within a week the edema of the lids and the erythema disappeared. [While erythematous, vesicular, and bullous manifestations have been recorded as arising from the internal and local employment of boric acid, the occurrence of solid edema of the eyelids, as in the case under consideration, is very rare.]

Eruption from Quinin resembling Erysipelas.—Stebbings[1] records a case of a woman 22 years of age who, for an acute catarrh in the head, took 8 gr. of quinin the afternoon preceding the advent of the eruption. The first symptom was an extreme puffiness about the face, principally on the right side and involving the right eyelid. The swelling extended down over the neck and across chest and breasts, showing also over limbs and arms; at some points about and along the margin of the infiltration there were intolerable itching and burning. This superficial dermatitis kept pace in its movement with the subcutaneous edema. There was a doughy feel, showing considerable infiltration under a moderate pressure—some pitting, and heaviness in muscular action of the face. [The case is of interest because of the close resemblance of the disease produced by quinin to common erysipelas, such forms of dermatitis from this drug being somewhat unusual.]

Mercurial eruptions are considered in their varied forms by Rosenthal,[2] who notes that inunction occasions them more frequently than mercury administered by the mouth. Under the use of the insoluble mercurial salts these eruptions, salivation, and stomatitis have decreased somewhat in frequency. When an eruption occurs other signs of mercurial intoxication seldom coexist. In cases in which the eruption is pronounced such general symptoms as fever,

[1] N. Am. Pract., Feb., 1896.

[2] Berl. klin. Woch., Nos. 23, 24, 1895.

headache, and depression may occur. Erythema, the several varieties of eczema, exfoliative dermatitis, pemphigus, folliculitis, and purpura, all may occur, pemphigus being the most serious manifestation, as illustrated by a case. Mercurial erythema may resemble the eruption of scarlatina or measles. All of the manifestations tend to take on a polymorphic character.

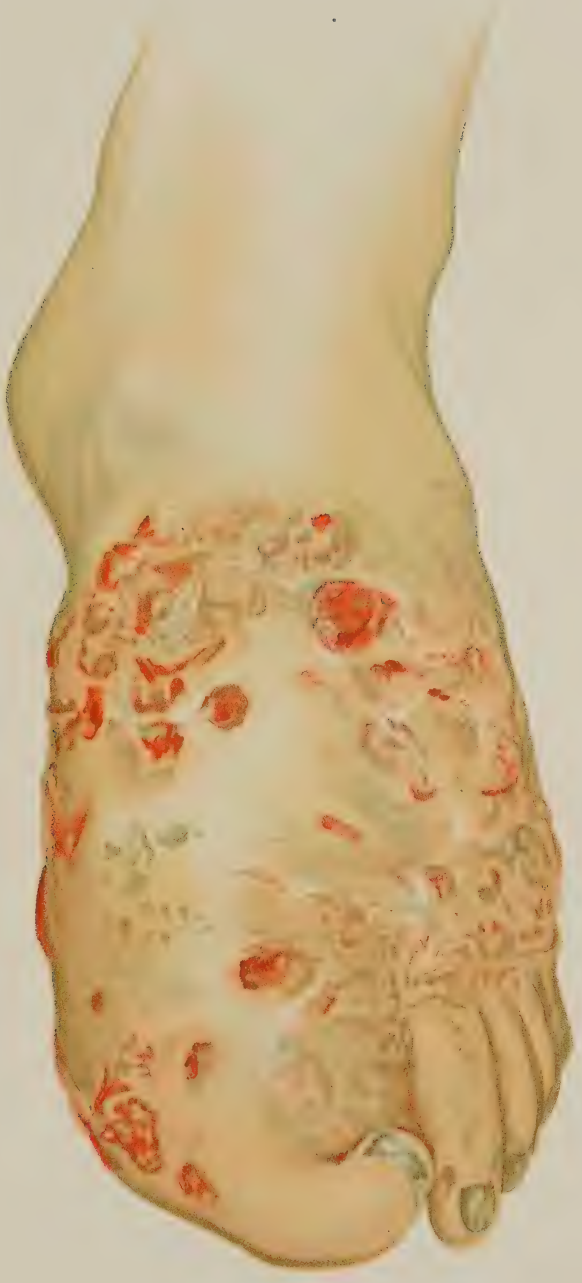
Bullous Eruption following the Administration of Arsenic.—Caigor[1] records the notes of the case of a delicate and anemic lady, aged 48, in whom vesicles and blebs, arising from a reddened and an edematous skin, formed upon the hands (palms and backs of fingers) 4 days after beginning the use of an arsenical mixture taken for sacral pain and debility. The blebs, some of them $\frac{3}{4}$ in. in diameter, never became purulent. In the course of 3 weeks the skin of the hands exfoliated, and at the end of a month recovery was nearly complete. The diagnosis of cheiropompholyx was made, the definite and symmetrical distribution of the lesions militating against the view that it was due to the arsenic that had been taken; 8 months later arsenic was again prescribed, and an eruption similar in all respects to the previous outbreak occurred, this being the third attack of the kind from which the patient had suffered. [There seems no reason to question the observation that the eruption was due to arsenic, and, furthermore, that it was an example of pompholyx, as the writer of the article suggests, but does not support. Pompholyx is a well-known, distinctly neurotic disease, and may be caused by arsenic precisely in the same manner as herpes zoster is often caused by this drug. We should designate the case, therefore, as one of cheiropompholyx produced by the ingestion of arsenic.]

A cutaneous outbreak presumably due to the ingestion of potassium acetate is reported by Cantrell.[2] The patient was a man aged 68, who had been taking the drug in 20-gr. doses, oft repeated, for some time. The eruption occupied the arms and forearms, and consisted of a number of aggregated lesions, resembling somewhat papular and papulovesicular herpes zoster, flat rather than acuminate, including the inflammatory areola. After discontinuing the drug the skin gradually regained its former healthy state, but not without having first manifested an erythematous and edematous condition in patches which suggested a superficial hemorrhage into the skin. The drug was subsequently given in the same dosage on two separate occasions, in both of which the same cutaneous manifestations appeared as in the first attack. [Eruptions of any kind following the administration of potassium acetate are rare. The eruption bore more resemblance to small patches of abortive herpes zoster than to any other recognized dermatosis; the lesions nevertheless differed from that disease. It is to be noted that the subject had taken the drug for a considerable period before any symptoms appeared on the skin.]

A rare form of skin-disease following the external use of iodin-liniment is reported by Dobie,[3] which occurred in a man of 24 who was suffering from pneumonia and advanced renal disease. The back of the trunk

[1] Brit. Med. Jour., Apr. 18, 1896. [2] N. Y. Med. Jour., Mar. 21, 1896.
[3] Lancet, Sept. 28, 1895.

was painted with diluted iodin-liniment morning and evening for 4 days. On the fifth day the patient's face was completely covered with a papular, pustular, and vesicular, and, in some localities, a bullous, eruption. The pustules were discrete and confluent, forming large encrusted sores, with swelling of the eyelids, lips, nose, and ears. There was, moreover, a copious discharge from the nostrils. The face was increased enormously in size. At the same time a perfectly different, purely papular eruption made its appearance upon the backs of the hands, wrists, and forearms. The eruption on the face gradually died away without scabbing. The papules on the hand continued prominent. Two weeks from the beginning of the cutaneous outbreak the patient died of uremic convulsions. The resemblance of the eruption to variola was noted by the reporter and his colleagues in the hospital, it being impossible to distinguish the difference without minute examination and inspection of the fluid on puncture of the papule and study of the history of the case. [This form of iodid-eruption has been described and depicted in the Atlas of Skin-diseases published 20 odd years ago by the New Sydenham Society, and is also referred to by Crocker in his Treatise on Skin-diseases. The case is peculiar and different from other similar cases in the fact that the eruption was produced by the local application of tincture of iodin on a region distant from the seat of the cutaneous disease. The abstractor has recently observed a somewhat similar case, although the dermatitis did not proceed beyond an erythema. Tincture of iodin was painted over the lumbar region, and in 24 hours an erythematous patch larger than an outspread hand manifested itself in the groin and down the inner surface of one thigh. The fluid had not run over and on to the thigh, nor had the groin or thigh been touched or handled by the patient.]



Sulfonal Exanthemata.—Walters[1] notes the previously reported cases, generally of erythema resembling scarlet fever, and reports 2 personal observations. He remarks that the eruption is mostly located in the follicles, and thence through confluence the efflorescence spreads, becoming large, reddened areas, with, in addition, vesicles. On the whole, the resemblance is to scarlet fever, which may in rare cases also show vesicles.

ACTINOMYCOSIS; MYCETOMA.

The Symptoms of Cutaneous Actinomycosis.—Monestié[2] states that actinomycosis affecting the skin may be secondary to extensive visceral invasion or may be local, as in connection with the inferior maxilla. The affection is most common on the face, and next on the hands. It manifests itself in two forms—the gummatous and the anthracoid, the former presenting cavities resembling the gummata of syphilis or of tuberculosis, containing pus, each opening by small fistulæ. The anthracoid form presents numerous fistulæ, which discharge a small amount of pus which does not collect at any one point. A pathognomonic sign, noted by Derville, is the presence of maculæ more or

[1] Therap. Monatsh., 1895, H. 12.

[2] Jour. des Sci. méd. de Lille, and Brit. Jour. of Dermat., Mar., 1896.

Drs. Hyde and Senn's case of mycetoma (Jour. of Cutan. and Gen.-Urin. Dis., Jan., 1896).

less pronounced according to the color of the surrounding skin. If the general color is pale, they are violaceous; if dark, they are black or bluish-gray. The spots vary from a pinhead to a bean in size, and possess a central whitish point, but pus may be obtained usually only in small quantity. Palpation and microscopic examination of the pus are both aids to diagnosis. Droplets of seropurulent matter may be squeezed out of fistulæ by gentle pressure on the tumor; or, if fistulæ do not exist, the softer portions of the tumor may be punctured and the yellow or bloody fluid thus obtained.

Therapeutics of Actinomycosis.—Rydygier[1] reports 2 cases treated successfully with local parenchymatous injections of potassium iodid, solutions of 1% being used. At first 1 syringeful was injected, but subsequently this dose was increased from 1 to 7 syringefuls at intervals of 3 to 7 days, and extending over a period of 6 weeks. In 1 case, after 1½ syringefuls had been injected into the infiltration on the side of the neck, a small abscess formed, which after incision decreased in size. After 2 or 3 more injections within a month the swelling gradually disappeared. In 1 case infection occurred through a tooth that had been injured by biting an apple which had been packed in barley-husks, a tumor on the neck below the jaw appearing a few weeks afterward. In the other case the disease, characterized by a large tumor on the abdomen, had probably been contracted from a horse that showed a swelling in the belly.

Mycetoma of the Foot as it Occurs in America.—Hyde and Senn[2] describe a case of this disease which they believe to be the first undoubted case of "Madura foot" occurring in the United States (see Plate 17). The case occurred in a man aged 20, born in Iowa of Bohemian parentage. The disease first appeared at the age of 7 years, when he was in the habit of walking barefoot in Cedar River. A nodule formed on the sole of the left foot soon afterward, which gradually grew, the disease ultimately involving the foot to such an extent that amputation had to be performed, although not much pain accompanied the disease. The clinical features, together with the microscopic examination, rendered the diagnosis positive, the case answering to the descriptions given by observers in India, especially Carter, Kanthack, and Vincent. The diagnosis of the reporters was confirmed, moreover, by Adami of Montreal. Hyde and Senn incline to the view that the fungus is not the same as that of actinomycosis, although closely related to it. They are disposed to regard Kemper's case of "podelcoma," published in the American Practitioner for 1876, as being a different form of disease.

Further Observations upon Madura Foot-disease in America.—Adami and Kirkpatrick[3] of Montreal further describe a case which was presented before the Association of American Physicians in 1895. The disease occurred in a French-Canadian 21 years of age, and was 10 years in developing. The authors distinguish clearly between mycetoma and actinomycosis, and they look upon Kemper's case of "podelcoma" as a doubtful

[1] Wien. klin. Woch., Sept. 12, 1895. [2] Jour. Cut. and Gen.-urin. Dis., Jan., 1896.
[3] Mont. Med. Jour., Jan., 1896.

one of true mycetoma, because of the acute and rapid course of the disease, 6 months only elapsing from the beginning until amputation had to be performed; the presence of great pain; the existence of vesicles and blebs; and the absence of the typical buttons of granulation-tissue. [The report of this case brings to light other cases of what were probably instances of this disease, as observed by Shepherd of Montreal, and by Pope, who operated on a Mexican, the specimen being in the Army Medical Museum at Washington. The case of Adami and Kirkpatrick is probably the first authentic one to be reported with care on this continent, that of Hyde and Senn having been reported somewhat later.]

The Skin-lesions of Syringomyelia.—Galloway[1] concludes that the weight of clinical evidence tends to corroborate the experimental results obtained by Mott, Sherrington, Ferrier, and Turner—namely, that sensory impulses in all their modes are conducted by gray matter, and not by the anterolateral or posterior ascending fibers, as once asserted. The possible conduction of educated touch in opposition to ordinary contact sensation by the white matter of the posterior columns is admitted. Further, in the numerous lesions of the skin that play so important a part in Morvan's type of the disease he feels inclined to consider that local infective processes play by far the predominant part in their production. He is also of the opinion that it is needless to seek for recondite cases for the production of the pustular and vesicular eruptions when there are plenty of common staphylococci and streptococci at hand to do the work. The writer also believes in the possibility of an ascending toxic neuritis from the affected part or due to the absorption of bacterial poisons. The scarcity of herpetic eruptions is evidence that the irregular pustulobullous eruptions met with were of local rather than of central origin.

Symmetrical Acrosphacelus without Raynaud's Phenomena.—Hutchinson[2] remarks that all who have studied in any detail the cases grouped together under the name of Raynaud's malady will admit that the time has arrived when they should be classified. They are not all alike, nor do they all tend to the same results. It would be well, indeed, he adds, if we could cease to use the term "Raynaud's disease" and speak rather of "Raynaud's phenomena." The phenomena in question are those of acroteric asphyxia, and are liable to variation at different times, being in many cases distinctly paroxysmal, and are to be explained by reference to the influence of the nervous system upon the blood-vessels. Many of the cases which have been quoted as examples of Raynaud's disease are, however, complicated, or even primarily induced, by organic disease of other parts. Although, unfortunately, Raynaud designated the affection which he described as "symmetrical gangrene of the extremities," it is now certain that many cases in which the phenomena which he describes as present are not attended by gangrene, and that some very definite forms of symmetrical gangrene are neither preceded nor followed by the paroxysmal phenomena referred to.

Two unusual cases are cited by Hutchinson—one in which there occurred

[1] Brit. Med. Jour., Dec., 21, 1895.

[2] Arch. of Surg., July, 1896.

PLATE 18.

Mr. Jonathan Hutchinson's cases of symmetrical gangrene of digits without Raynaud's phenomena (Arch. of Surg., July, 1896).

a sudden illness attended by severe pain in the chest and symmetrical gangrene of all the digits, the nose, and the ears, terminating in complete recovery of health. In the other case symmetrical acrosphacelus occurred as a single attack in an adult man previously in good health, and followed, after separation of the sloughs, by complete recovery. Without giving the full notes of these cases, it may be said that they appear to agree in the following points: In both the patient was a robust man who had never had any serious illness before. In neither was there any former history of rheumatism, gout, or syphilis. In neither had there been any peculiarity of the circulation observed previously. In both the stumps healed soundly and the restoration of the circulation appeared to be complete. No occlusion of the distal arteries was ever proved in either case. No heart-disease was shown. In both the onset of the attack was sudden, the hands, toes, ears, and nose being involved. Both patients had a serious illness at the time the gangrene commenced; in one diphtheria was diagnosed, in the other rheumatic fever. In both it is probable that a very definite condition of asphyxia or venous turgescence was present in the early stage and persisted until the gangrene was complete. Against the belief that there was any mechanical occlusion of the affected vessels we have the fact that the sphacelus was symmetrical, and that it affected the nose and ears as well as the digits. The nervous system may have had its share of the process, but it was not primarily at fault. [Pictures illustrating these interesting and instructive cases are reproduced (see Plate 18).]

HEMORRHAGES.

Relation of Peliosis to the Other Forms of Idiopathic Purpura.—Diehl,[1] after calling attention to the fact that there exists a difference of opinion as to the relation peliosis rheumatica holds to purpura simplex and purpura hæmorrhagica, brings forward a case which he believes proves the theory that purpura simplex, purpura hæmorrhagica, and peliosis are one and same affection, each presenting the same local manifestations and differing only in their individual severity. The disease in this case began as a simplex purpura and continued as such for a long time, and was about disappearing when a sudden change of atmospheric conditions produced an exacerbation with distinct rheumatic symptoms.

The Relationship of Purpura Rheumatica to Erythema Exsudativum Multiforme.—Mackenzie[2] discusses the subject from the standpoint of general medicine, and, after alluding to the recent articles of Osler, Wright, and Fayrer, gives his own experience with purpura rheumatica, citing personal cases. He believes that whilst purpura and erythema multiforme own many causes, in a large proportion of cases they suggest blood-alteration, and urticaria is nosologically closely allied to them. In this connection Wright's observations,[3] pointing out that in urticaria diminished coagulability of the blood is probably a factor, are of value. Mackenzie thinks that the term

[1] Buffalo M. and S. Jour., Jan., 1896. [2] Brit. Jour. of Dermat., Apr., 1896.
[3] Lancet, Jan. 18, 1896.

purpura rheumatica or purpuric rheumatism should be restricted, to show its intimate relation with rheumatism, which justifies regarding it, along with arthritis, endocarditis, chorea, and erythema nodosum, as in itself an expression of rheumatism. In many cases it is purely hemorrhagic from first to last. While it presents many features in common with exudative erythema, it nevertheless presents such definite characters and pursues such an uniform course that it is advisable to recognize it as a distinct clinical type.

A Remarkable Case of Purpuric Eruption ending in Gangrene, apparently Caused by Sodium Salicylate.—Shepherd[1] of Montreal records a case occurring in a strong man of 32, who was admitted to the hospital for supposed acute rheumatism. After three 20-gr. doses of sodium salicylate an eruption appeared on the body and extremities looking very much like urticaria, but without much itching. Successive crops appearing, the drug was discontinued. The spots became petechial, raised, and considerably indurated. In some places a slough resulted from the excessive hemorrhage, which on separating left well-marked ulcers which were very slow to heal. Myalgic and arthralgic pains accompanied the eruption. The period occupied by the disease was 33 days. All the superficial parts of the body, except the palms and soles, were affected. The mouth, soft palate, tongue, pharynx, and larynx were all seats of the eruption, and there was much edematous swelling of the mucous membrane. [Eruptions following the internal administration of sodium salicylate are not rare, but they are usually erythematous, edematous, or urticarial and itchy, rather than hemorrhagic. The case reported bears resemblance to purpura rheumatica or peliosis rheumatica in its symptomatology, but there is no reason to doubt that the disease was either produced or influenced by the drug.]

Case of Purpura Hæmorrhagica (Acute Exudative Erythema).—Fayrer[2] reports a case in which there occurred extensive and pronounced hemorrhagic patches in the skin, the patient being a strong, well-developed man aged 24, in the army, who never before had been ill, but he had the aspect of being anemic. The skin was abnormally pale and the lips and conjunctiva were generally pallid. The disease began suddenly with acute articular rheumatoid symptoms, especially swelling, and with sore mouth and gums, and later with puffing of the face. A week later spontaneous large purpuric patches occurred about his face, and within a few days on the thighs. Within the following week edema of the glottis and of the tongue and mouth, and later ulceration, occurred. New purpuric lesions continued to appear, and at the end of about 3 months from the beginning of the illness he had recovered.

The reporter thinks there is little ground for regarding the articular and other swellings as being due to rheumatism. The temperature did not indicate an attack of severe rheumatism, and the swelling was peculiar, the edema being great, and was followed by slight staining, which preceded the hemorrhagic patches which ultimately appeared. There was no cardiac disease. The pathology of this disease is obscure, and the case is recorded as a clinical con-

[1] Jour. Cut. and Gen.-urin. Dis., Jan., 1896. [2] Brit. Jour. of Dermat., Aar., 1896.

tribution to the relationship of purpura rheumatica, purpura hæmorrhagica, erythema nodosum, and erythema multiforme. [The title of the article is "Purpura Hæmorrhagica (Acute Erythema Multiforme)," but the notes of the case show no cutaneous lesions that could possibly be regarded as erythematous. They were purpuric, and only purpuric, from the beginning to the end; hence the term "erythema multiforme" as applied to this and to other like cases is a misnomer. That the etiology and pathology of erythema multiforme and purpura hæmorrhagica are in many cases closely allied there can be no doubt, but this is no reason why the terms should be used synonymously or together, as in the case reported.]

NEUROSES.

Pathology of Itching, and its Treatment by Large Doses of Calcium Chlorid.—Savill[1] expresses the view that itching is either primary or secondary, no eruption being present in the former variety—the latter, however, being accompanied by or succeeded by some form of eruption, as, for example, eczema. The secondary form may be explained by involvement of the terminal nerve-fibers in the lesions of the skin. The explanation of primary itching is probably to be found in some blood-change, in proof of which statement it may be noted that it is usually generalized in distribution, and varies in intensity from time to time, often from hour to hour or day to day. Certain articles of food cause it or aggravate it. In certain forms of itching, as that met with in diabetes, gout, jaundice, changes in the blood are known to occur, and morphin introduced into the blood gives rise to itching. Upon these grounds the author administered large doses of calcium chlorid in both primary and secondary itching, and with success. Large doses often succeeded when smaller ones failed, and in the large number of cases in which it was employed there were no absolute failures. The dose was never less than 20 gr. t. i. d., largely diluted with water, after meals.

Two Cases of Pruritus cured by Antipyrin.—F. Arnstein and Atoniak[2] report 2 chronic cases in which this drug acted happily. The first case occurred in a woman 28 years of age, the disease beginning upon the vulva, from which region it progressively extended over the thighs, abdomen, back, neck, chest, and upper extremities. There were no alterations in the texture of the skin. In the course of the fourth month of the disease antipyrin was taken twice daily, and at the end of 10 days the pruritus had completely disappeared. The second case occurred in a woman aged 66 years, the subject of senile pruritus. Under moderate doses 4 times daily the disease entirely disappeared in 2 weeks. [There is no doubt that not only this particular drug, but others belonging to the same group, are of value in pruritus, and also in other diseases, as dermatitis herpetiformis, in which the terminal nerve-filaments are involved. Antipyrin was recommended for pruritus 5 years ago, in 1891, by Blaschko of Berlin, under the name of phenazone.]

[2] Jour. des Mal. cut. et syph., Fév., 1896.

HYPERTROPHIES.

Case of Ichthyosis Congenita with some Unusual Features.—Cabot[1] reports an example of this disease which occurred in the practice of Dr. Roth of Newark, who states that when the baby was born the outer canthi of the eyelids were drawn downward and inward, almost completely closing the eyeballs from view. There was no vernix caseosa on the child's head or body, the skin being perfectly dry at birth. The nose was like a white, bony prominence protruding from the face. The angles of the mouth were tightly drawn downward and inward and had a cracked appearance. The ears were bound down to the head and were immovable, and looked as though they were gangrenous. There was no hair on the child's head; both nares were closed, so that an incision into each one had to be made to permit the child to breathe; the rest of the body—that is, the skin—had an appearance as though the child was enveloped in oil-silk, was shrivelled, and not glistening, but dull. The child was born at 7 months of utero gestation. The mother was 4 days in labor. The child was weak and marasmic at birth, but at the end of 2 months had gradually gained in weight, and became fairly healthy except for the skin-disease and occasional attacks of bronchitis. Subsequently, however, at the age of 16 months, the child died as a result of general malnutrition, marked hyperpyrexic symptoms being particularly notable. The case is interesting in that the child lived much longer than is usual in congenital ichthyosis of this type, it being very exceptional in this form of the disease for children to live more than a few days. [Comparatively few cases of this form of keratosis are on record. It is to be distinguished from the different and common forms of ichthyosis met with in infancy, childhood, and adult life, which appears either as I. simplex or hystrix.]

Ichthyosis with Hypertrophy simulating Scleroderma.—Hallopeau and Jeanselme[2] call attention to the observation that several writers have described defective development or atrophy of the skin (as in the cases reported by Audry in Jour. des Mal. cut. et syph., 1895). A case is reported at length, the authors concluding their observations—1. Ichthyosis may be accompanied by a defect in the development of the skin simulating scleroderma; 2. It may result in functional disturbances, such as the impossibility of closing completely the eyelids; 3. The movements of the fingers may be equally involved; 4. The derma is in such cases thinned in places, and its elasticity is lessened; 5. These cutaneous alterations coexist with a defect of development, very pronounced, of the underlying parts, and in particular of the skeleton of the extremities, as of the auricular cartilages; 6. The proximate cause of these alterations is in all probability an arrest of development of the skeleton and of the skin, leading on to their hypertrophy.

The So-called Parasites of Molluscum Contagiosum.—Gilchrist[3] says that among the chief supporters of the parasitic view of this disease may

[1] Med. Rec., July 6, 1895. [2] Jour. des Mal. cut. et syph., Fév., 1896.

[3] Johns Hopkins Hosp. Rep., vol. i.

PLATE 19.

Mr. Jonathan Hutchinson's case of morphœa herpetiformis (Brit. Med. Jour., June 1, 1895).

be mentioned Neisser, Mansuroff, Ziegler, L. Pfeiffer, and Rieder. Unna in his last work (Histopathology of the Diseases of the Skin) gives a thorough view of the whole subject, and mentions the names of Retzius and Klebs, Bollinger, Darier, Vidal, and Leloir as being still in favor of the parasitic theory. At the present time, however, the majority of dermatologists are of the opinion that molluscum contagiosum is not a parasitic disease, and that the "molluscum bodies" are the result of degenerative processes occurring in the epithelial cells of the epidermis. With respect to the contagiousness of the disease authorities are still divided. The supporters of the parasite theory claim to notice a great resemblance between the molluscum bodies and coccidia, but as far as Gilchrist's observations have gone it is difficult to see upon the presence of what common characteristic features their conclusions are based. Comparing these bodies with undoubted protozoa, Gilchrist has found no developmental forms of the "molluscum bodies," whereas developmental forms of undoubted protozoa were very numerous. In the neighborhood of "molluscum bodies" no inflammatory changes were produced, whereas the protozoa always set up an acute inflammatory affection, as well as producing chronic changes. "Molluscum bodies" are only found in the epidermis, and are absent from the corium, whereas the protozoa attack not only the epidermis and corium, but are found in large numbers also in the subcutaneous tissue, as well as in the neighboring lymphatic glands. Inoculation-experiments with molluscum contagiosum, although occasionally successful, have very often shown negative results, whereas inoculations of the protozoa of one of Gilchrist's cases into animals were successfully carried out. The "molluscum bodies" are perfectly homogeneous, and have been traced by many competent observers as originating from gradual degenerative changes in the prickle-cells of the epidermis. The different stages of development of the protozoa are not degenerative; they have also been carefully followed, and show no resemblance to those taking place in the molluscum bodies. Broadly speaking, when compared together under the microscope there is little or no resemblance between the protozoa observed by Gilchrist and the molluscum bodies. His observations have made him take sides with those investigators who deny that the "molluscum bodies" have any claim to be considered protozoa, and who hold that they are probably derived from degenerative epithelial cells.

Nature of the Cells in Molluscum Contagiosum.—Kuznitzky[1] believes that we may consider the following points as established: 1. The disease is contagious; 2. It is the product of epithelial hypertrophy and has no relation with the sebaceous glands; 3. The epithelial proliferation begins, as a rule, in the upper layers of the mucous layer, and not in the apertures of the follicles or in the roots of the hair. The question whether the epithelial changes are of a degenerative nature or represent organized parasites is not yet decided. To determine, if possible, the last point the author examined microscopically sections of molluscum tumors prepared by the alcohol-celloidin method and stained with Unna's polychrome methylene-blue or hematoxylin.

[1] Arch. f. Dermat. u. Syph., Bd. xxx. 1, 2.

He believes, first, that the so-called molluscum bodies are in genetic relation with the normal prickle-cells; secondly, that the changed cells are not coccidia. [In the same journal, Bd. xxx. H. 3 Touton, who believes in the coccidial theory of these peculiar bodies, replies to Kuznitzky's article, stating that until Kuznitzky defines more accurately what he means by "homogeneous" degeneration he must still hold to the parasitic nature of these bodies. He is of opinion that the changes of the nuclei described by Kuznitzky are contractions produced artificially.]

Pathology of Pigment-anomalies of the Skin.—Orlandi[1] reports cases, and observes concerning the pathogenesis of pigmentary affections that they are connected with part of the sympathetic system, especially with the fibers which are prominent in governing pigmentation. From the observation that vitiligo is incurable, and that chloasma, on the other hand, sometimes passes away spontaneously, the writer questions if there may not be an alteration of the involved sympathetic fibers in the former and merely an irritation in the latter.

Morphœa Herpetiformis.—Hutchinson[2] contributes a lengthy and valuable article on the subject of morphea, illustrated by some rare cases, one of which is here reproduced in color (see Plate 19). The subject was a woman aged 63: on the outer part of her foot and ankle there existed a large, irregularly-shaped, hardened patch of skin which had assumed a color of yellow ivory or smooth washleather. To the finger the affected skin felt board-like, and it was quite impossible to pinch it or lift it from the subjacent parts. A certain amount of contraction was present by which the three outer toes were drawn upward and the movements of the ankle were much impeded. At the margin of the affected part the skin was somewhat congested, and on the side of the leg, about 4 in. above the outer malleolus, there was an ulcer as large as a half-dollar. The condition had existed about 9 months. The disease began as a reddish ring on the dorsum of the foot; other lesions followed near it, and in 2 months the patch was well defined. Ulceration did not take place until 3 or 4 months later. The morbid process attained its height in 8 months, and during the 2 years which have subsequently elapsed the lesions have been slowly subsiding. The patient has been in fair health throughout and has had no similar patches elsewhere. The portion of the skin involved is exactly that supplied by the terminal twigs of the short saphena nerves, although the outlines of the patch are not much suggestive of nerve-distribution. The ulcer has since healed, and the whiteness and induration of the skin have to a very large extent disappeared. There remains, however, an almost scar-like condition of the affected skin, which is of a dusky color and is adherent to the parts beneath.

The writer believes that the term "herpetiform" may be suitably applied to all cases of morphea in which the changes are arranged in bands or after the manner of a corymb or panicle. More than a few of these cases are bilateral, and in a certain number the streaks may be arranged almost symmetrically. A tendency to be bilateral and to occur on many parts at once, the writer

[1] Monatsh. f. prakt. Dermat., Bd. xxii. No. 6. [2] Brit. Med. Jour., June 1, 1895.

observes, is very rare in zoster and very common in morphea, but this does not in the least invalidate the theory of the nerve-distribution of the latter. It proves only that many nerves may be affected at the same time. In all cases of multiple morphea which should be called "herpetiform" it will be observed that there are areas of healthy skin between the diseased portions, and that the affected areas are arranged according to the distribution of nerves. Mr. Hutchinson directs attention to rare cases of morphea which are distinctly opposed to the nerve-distribution theory, as in patches occasionally observed which are placed transversely. The name "morphea" is retained and preferred rather than the new one of "diffuse scleroderma." The latter is a pathologic term; it denotes a theory, and is applicable to many affections, and to only certain stages of each. Morphea is a clinical term, is well understood in its conventional signification, and has the great advantage of being almost meaningless as regards pathologic theory.

The subject of morphea is divided into three groups: 1. Herpetiform morphea, in which the patches are arranged on the pattern of herpes in streaks or bands, and, however extensively bilateral, seldom or never with exact symmetry; 2. Acroteric morphea, in which, although the whole skin may suffer more or less, the beginning and the greatest severity of the disease are almost invariably at the extremities. There is no location in streaks, symmetry is always marked, and Raynaud's phenomena are not unusual. This form is met with almost solely in adult women, and shows no tendency to spontaneous cure; 3. In this group are comprised hide-bound conditions of the skin in which the subcutaneous tissue, rather than the skin itself, is implicated. In this division are to be placed for the present certain cases which differ more or less definitely from both the preceding, and concerning the exact relations of which it is very difficult to speak. There are no ivory patches nor are the extremities affected in preference. Cases illustrating these several varieties are given. [This article is of particular interest and value because of the large, varied, and rare clinical material brought forward, and because the writer's observations on this disease must be considered as carrying great weight. Probably no observer living has had the opportunity of studying and following throughout life so many cases of morphea as Mr. Hutchinson.]

NEW GROWTHS.

Treatment of Nævus Unius Lateris.—Ransom[1] describes fully a case of this disease occurring in a woman of 20, occupying the upper portion of the trunk and the thigh. Various methods of removing the growths were tried, including curetting with and without the use of chromic acid; afterward electrolysis, the galvanocautery; the application of nitric, acetic, and chromic acids; but the most satisfactory procedure, both from the patient's standpoint of comfort and in the results obtained, was the use of a flat-pointed scissors. The skin was picked up between the thumb and fingers, and the top of the

[1] Jour. of Cut. and Gen.-urin. Dis., Apr., 1896.

ridge so made was snipped off, the cut being superficial and extending not quite through the skin proper.

Angiokeratoma of the Scrotum.—Fordyce[1] gives the notes and the histopathology of a case of this disease occurring in a man of 60. The scrotum was the seat of a great number of pinhead-sized, spherical, dark-purple tumors, arranged in a linear manner, as if following the superficial vascular supply of the affected region. Pressure caused the color of the majority of the tumors to disappear. They were distinctly raised above the surface of the skin, seeming to rest on it rather than to be imbedded in it. Some of them were covered by a slightly thickened horny layer, under which minute dark points could be seen, which gave the little tumors a warty-like appearance. There was no pain, itching, or other subjective symptoms. Puncture of the lesions was followed by slight bleeding. Dilatation of the capillary vessels is regarded by all the observers who have studied the disease as the primary and essential condition, the changes in the epidermis, especially the corneous layer, being secondary. Microscopic sections showed that spaces existed in the mucous layer of the epidermis in a marked degree, and that these spaces were caused probably by a down-growth of the cells of this layer, producing a constriction of the terminal loops and their resulting distention. The case reported differs from other similar cases in the localization of the disease, the absence of chilblains as a cause, and in the small amount of keratosis on the summits of the lesions. [These growths have been successfully treated by electrolytic puncture with the negative pole and by galvanocautery.]

Xanthoma Diabeticorum (so called); its Place among the Dermatoses.—Johnston[2] publishes an account of a case in which there were some peculiar features. The man, aged 57, was first seen in 1893, when he was suffering from diabetes; under treatment the amount of sugar was reduced. The xanthoma now appeared in the form of a few scattered papules on the elbow. Six months later the disease was widely disseminated on all parts except the face, chest, and abdomen. The eruption consisted of papules, dull red in color, becoming pink as they faded out; discrete or confluent, hard to the touch, and sharply defined; the lesions varied from a line in diameter to large raised patches on the soles $\frac{1}{2}$ in. in diameter; many had the common yellowish-white apices; some had not, nor did pressure bring them out. Six months later many of the lesions had entirely vanished. In the autumn of the same year the man began to drink heavily; the amount of urine passed and the proportion of contained sugar increased day by day, until the latter reached 8%, when the eruption began to reappear. The activity of the process was clearly shown by the fiery-red color of the lesions, in marked contrast to the pale pink color seen during involution. The tint was compared to that of raw beef. At this time the nodules had coalesced into enormous plaques 4 by 8 in. in size, dotted here and there with the yellowish central point of the individual lesion. Not less than 2500 lesions now existed. Pressure produced a sensation of ten-

[1] Jour. of Cut. and Gen.-urin. Dis., Mar., 1896.

[2] Ibid., May, 1894, and Oct., 1895.

derness and prickling, and on account of the extreme hardness of the lesions he seemed to be lying on or sitting on a bag of shot. It was a curious and notable fact that while whisky was kept from him no involution took place, but if allowed about a pint and a half regularly each day improvement began. Dr. Johnston concludes that since xanthoma multiplex is an anomaly of formation, and that xanthoma diabeticorum is an inflammation due to an irritative process ending in a granulofatty degeneration, it is not proper to class them together as varieties of the same disease. Xanthoma multiplex is therefore properly placed and named, being really a xanthoma—that is, a yellow tumor. He would propose for the other the term "dermatitis xanthomatoides diabeticorum"—in other words, an inflammatory skin-disease which occurs in diabetics who have a personal idiosyncrasy leading to the formation, and which resembles xanthoma. It should thus be placed among the inflammations, and not the tumors.

Granuloma Fungoides.—Breakey [1] records a case of this disease (Fig.

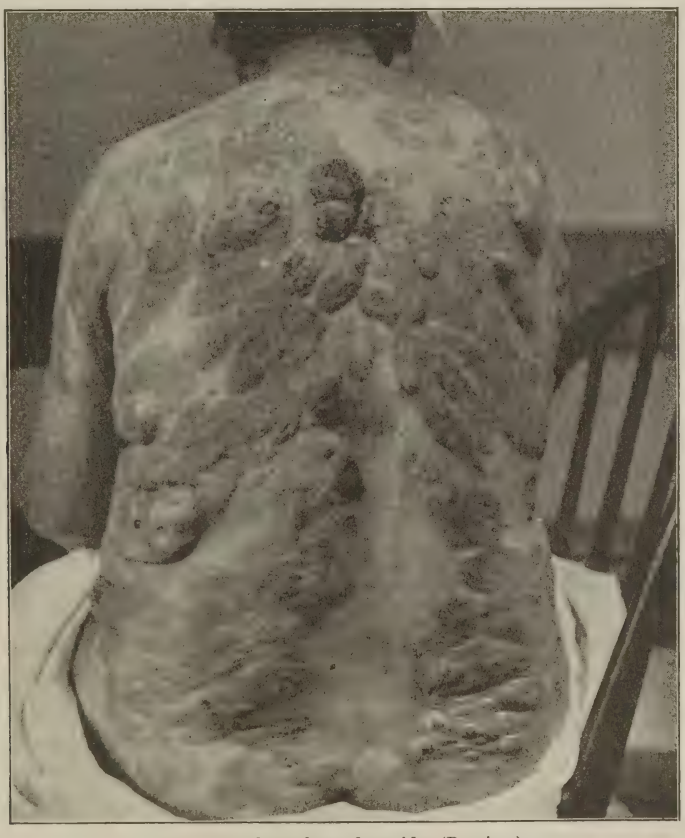

FIG. 163.—Granuloma fungoides (Breakey).

163) in a German woman of 56. The disease affecting the skin began 6 years before, at the beginning of the menopause, on the backs of hand and feet, in

[1] Jour. of Cut. and Gen.-urin. Dis., Aug., 1895.

the form of red spots which gradually spread all over the body, sometimes scaly, always itchy, never ulcerated. These macular lesions nearly all disappeared in the course of about 2 years, and the woman remained almost well for the next 2 years; then the spots broke out again nearly over the whole body at once, and have been better and worse since. The growths were more numerous and larger 2 or 3 months ago than at any other time. Many of the large tumors grew very rapidly (in from 2 days' to 2 weeks' time), and other tumors, half the size and thickness of the hand, have disappeared in a week. The general surface of the body, especially the trunk and extremities, is the seat of very numerous, variously sized and shaped erythematous infiltrated macules, tending to become flat or elevated nodular tumors. The lesions exist in all stages of development, for the most part in the form of large dollar- or hand-sized nodular infiltrations. Some of the more elevated tumors show erosions, from which reddened, hyperemic surfaces a bloody puriform discharge oozes. Here and there, especially in the axillæ and in the groins, on the thighs and on the lateral parts of the abdomen, are numerous large nodular, fungoid masses resembling flattened tomatoes. The legs and feet are much enlarged, and show dry, hard, dark-colored skin. There is not much tenderness and pain is absent, but the itching is constant and marked. The point of interest in this case concerns the diagnosis, the microscope tending to confirm the view of the growth being sarcomatous, while the clinical conditions and history point distinctly to granuloma fungoides. The photograph is reproduced. [While cases occasionally are met which exhibit the clinical symptoms and the histopathology of sarcoma, the majority are peculiar and do not show a close relationship to that disease, so that it is eminently proper that, for the present, both forms of the disease should be described separately. The clinical history of granuloma fungoides (or "mycosis fungoides," as French writers incline to call it, although there is not at present the least proof that it is mycotic) is in most cases remarkable, and is so different from that of any other disease as to entitle it to special study.]

Is this Leprosy?—McDougal of Ohio[1] presents 2 interesting cases (Fig. 164) upon which he raises a question of correct diagnosis. The first concerns a girl of 18. The present disease first manifested itself at the early age of 15 months in the form of "abscesses" in the legs. In 2 or 3 years the toes began to ulcerate and come off, and then the hands became involved. The flesh ulcerated from the fingers, leaving dry, blackened bones exposed. She menstruated with moderate regularity from the age of 14 until 1 year ago, when the menses stopped. At the date of the notes the left hand and lower forearm were swollen and rather firmly thickened, the hand and wrist being about twice the normal size. The distal phalanges were all lost except the little finger and thumb, and the stumps are healed. The hand is being self-amputated at the radiocarpal articulation by a narrow encircling ulcerative process, and the work is so near completion that only the ulnar vessels and some of the tendons remain (see photograph). Both surfaces are covered by

[1] Jour. of Am. Med. Assoc., Nov. 2, 1895.

granulations bathed with extremely foul-smelling pus, and are yet held in close apposition, except at the bordering skin, where some retraction has taken place in the healing process which has begun. The right hand and fingers were somewhat swollen and clubbed, and all the distal phalanges except those of the little finger and thumb were lost. The wrist-joint was somewhat deformed,

FIG. 164.—McDougal's cases of leprosy (?).

because of an unnatural prominence of the head of the ulna on the dorsal side. From the left foot the first and second toes were entirely lost, the third toe was off at the proximal phalangeal joint, and the fifth toe was all lost. On the plantar surface of the stump of the great toe was a thick, dark crust covering an unhealed ulcer. In the middle of the left sole was an ulcer the size of a silver half-dollar which reached deep into the foot and from which there came a very offensive discharge. From the right foot the great toe was lost, the second and third were off at middle of proximal phalanx, and the fourth was pointed upward, so that it was considerably out of line with the others. The little toe was not affected, except that it was involved in the general thickening of the

foot. All the affected members were more or less anesthetic, the thermal anesthesia being especially marked. There was a blister the size of a silver quarter-dollar on the back of the right arm just above the olecranon. The end of the tongue had been destroyed by ulcerations that had healed; the left side of lower lip and both wings of nose had suffered in the same way; the lower jaw had likewise suffered loss of bone, teeth, and gum; the eyes were weak, blinked, and vision was poor. A month later she was seen again, when she was sweating freely, though the house was cold, and her pulse was accelerated. There was great pain in neck and left leg. She had fallen several times limp and motionless and had choking spells. The hand was still further separated from the arm and hung downward. There was an eruption on left side of neck and front of right leg composed of dark, yellowish-brown macules thickly set and giving a dappled look. The self-amputated hand was given to the supervising surgeon general, U. S. Marine Hospital, the report being that the disease was "neither leprosy nor tuberculosis, which by exclusion throws some weight upon the suspicion of syphilis."

This patient had a sister 8 years of age who had been affected in the same manner for 3 years. Her feet were clubbed, her legs stocky; the great toe of left foot was off at the middle of the proximal phalanx, and was crusted. The distal phalanx of the second toe was lost; the right great toe was the same as the left. She manifested other symptoms similar to those which have been noted in her sister. The reporter thinks that Raynaud's disease, Morvan's disease or syringomyelia, and syphilis must be excluded, believing as concerns syphilis that no such history and combination of symptoms have ever been approached in any case of syphilis recorded. The father of the patients had a disease of the nose which, as far as the description given goes, the reporter thinks might have been syphilis, lupus, or some other disease, but he inclines to leprosy, and adds that, admitting syphilis might show itself by such unprecedented manifestations in a single case, it multiplies the improbabilities very greatly that two such unusual cases should occur together and be alike, for, considering the difference in duration, they are as nearly alike as two cases of any disease usually are. Photographs are here reproduced. [We hesitate to express a positive opinion on these very interesting cases, but we do not think that the diagnosis of lepra should be made without further investigation. The history is in favor of syphilis rather than lepra, the likelihood of the father having had lepra being hardly worthy of consideration.]

Leprosy in Nova Scotia.—Ashmead[1] brings forward considerable correspondence and a number of facts which go to show—1. That leprosy does not now exist among the Micmacs, and that they never were affected with this disease; 2. That in Nova Scotia leprosy exists in one Irish family in the island of Cape Breton, and only among the descendants of Scotch Highlanders in other parts of the province. The original MacCarthy leper came from New Brunswick, the supposed date of his leprosy being 1845; 3. That in the province of New Brunswick leprosy was introduced by a French vessel from

[1] Jour. Am. Med. Assoc., Feb. 1, 1896.

ORDER BLANK.

(Tear off the above order on this line.

GENERAL INFORMATION.

One Price. One price absolutely without deviation. No discounts allowed, regardless of the number of books purchased at one time. Prices on all works have been fixed extremely low, with the view to selling them strictly net and for cash.

Orders. An order accompanied by remittance will receive prompt attention, books being sent to any address in the United States, by mail or express, all charges prepaid. We prefer to send books **by express** when possible, and if sent C. O. D. **we pay all charges** for returning the money. Small orders of three dollars or less **must invariably be accompanied by remittance.**

How to Send Money by Mail. There are four ways by which money can be sent at our risk, namely: a post-office money order, an express money order, a bank-check (draft), and in a registered letter. Money sent in any other way is at the sender's risk. Silver should not be sent through the mail.

Shipments. All books, being packed in patent metal-edged boxes, necessarily reach our patrons by mail or express in excellent condition.

Subscription Books. Books in our catalogue marked "For sale by subscription only" may be secured by ordering them through any of our authorized travelling salesmen, or direct from the Philadelphia office; they are **not** for sale by booksellers. All other books in our catalogue can be procured of any bookseller at the advertised price, or directly from us. *We handle only our own publications*, and cannot supply second-hand books nor the publications of other houses.

Latest Editions. In every instance the latest revised edition is sent.

Bindings. In ordering, be careful to state the style of binding desired—Cloth, Sheep, or Half Morocco.

Catalogues and Descriptive Circulars. A complete descriptive circular, giving table of contents, etc. of any book sold by subscription only, will be sent free on application.

MR. SAUNDERS points with a feeling of pardonable pride to the success that has attended every publication issued from his house. A record such as this is one that is without parallel in the history of medical publication.

Since the appearance of the first number of the SAUNDERS QUESTION COMPENDS, OVER 160,000 COPIES of these invaluable self-helps have been sold to physicians and students.

The success of the AMERICAN TEXT-BOOKS has also been phenomenal, as is attested by the fact that in the short period since the publication of the first volume of the series OVER 90,000 COPIES of these popular text-books have been sold in this country and abroad.

Only books of rare merit could have attained such extraordinary sales, which furnish indisputable evidence of the high standing acquired by these books among physicians and students throughout the civilized world.

W. B. SAUNDERS, Publisher,

925 Walnut Street, Philadelphia.

the Levant in the year 1758, and the disease still exists there among the "degenerated" French.

Leprosy with Special Reference to Kashmir.—Mitra[1] contrasts the prevalence of this disease in the valley of Kashmir with that met with in the Goojar country, situated on the slopes of the mountains not far distant. Rice forms the staple food of the Kashmirs, but meat and fish, fresh or dried, are also used, the boatmen on Woolar Lake living principally on fish. Syphilitic diseases are widespread among all classes, to the extent that the disease has almost assumed the magnitude of a national calamity. The habits of the people are very unclean, and there is utter disregard of public and private hygiene. Yet among these people leprosy is a rare disease. What may be the cause of this comparative immunity of the inhabitants of the Kashmir Valley from leprosy is difficult to determine, for this people are almost surrounded by leper neighbors, among whom the disease must have been prevalent for a long time. The Goojars reside on the slopes of the nearby mountains and are agriculturists, their food being Indian corn, wheat, and milk. Among them leprosy is a common disease. The prevalence of the disease in one people and its rarity in another neighboring community is difficult to account for. Concerning the contagiousness of leprosy, the writer states that he is familiar with 1 instance of a wife who acquired leprosy from an affected husband; 5 years after marriage the husband showed symptoms of leprosy; after another 5 years the wife became affected. On the other hand, he cites the instance of a family in which the grandmother suffered from a very bad type of ulcerative leprosy. She was nursed by her daughters and granddaughters. The old woman died 5 years ago. None of the family have become diseased, nor does he know of any case of contagion except that referred to. He thinks Hutchinson's fish-theory untenable, because the Goojars do not eat any fish. The treatment of the disease in this writer's hands has been unsatisfactory. Nerve-stretching is often useful, but it does not cure. He does not regard the disease as curable, but states that under proper medical care patients can be made comparatively free from symptoms. [The case cited in proof of the contagiousness of the disease is far from being convincing. Analyzed closely, it proves nothing beyond the fact that the disease manifested itself after a period of 5 years of married life in the wife, the husband having been leprous during that period. There are no facts that point to the mode of inoculation.]

A Promising Treatment of Leprosy.—Crocker[2] records 2 cases of leprosy in which hypodermic injections of mercuric chlorid produced improvement in the symptoms. A Pravaz syringeful of a solution containing 6 gr. to the ounce, the dose being $\frac{1}{5}$ gr., was injected deeply into the buttocks once a week. The results obtained were so favorable as to justify a further trial of the drug in other cases. In the first case in which this treatment was employed the diagnosis of syphilis had been made, and the improvement was so decided that it was supposed that that diagnosis was correct, but subsequent crusts proved that the disease was unquestionably leprosy.

[1] Indian Med. Rec, Aug. 1, 1895.

[2] Lancet, Aug. 8, 1896.

Lepra, especially as Met with in Iceland.—Ehlers,[1] whose observations were made chiefly in Iceland, does not believe in the theory advanced by Zambaco Pascha that lepra mutilans and Morvan's disease are one and the same malady. He does not believe that autocthonous leprosy exists, no proof being presented by observers like Zambaco Pascha in substantiation of this view. Leprosy still exists in France, as Leloir, Zambaco Pascha, and others have shown, and Ehlers thinks that the disease is probably carried by the fishermen of Bretagne, France, who to the number of 4000 travel annually to Iceland and back. He holds the view [like Armauer Hansen of Norway, the discoverer of the bacillus lepræ] that the malady is contagious, and that heredity plays no part in its production. [The brochure is copiously illustrated with photographs of Icelandic leprous subjects, showing the disease in its several varieties and in diverse stages. It is a valuable contribution to our knowledge of the etiology of lepra, and should be consulted by all who have in any way the care of lepers, foreign or indigenous. Proof of the contagiousness of the disease has been steadily accumulating during the past decade, until now no dermatologist questions the statement, but the mode of contagion and the conditions and circumstances under which it takes place are all still as mysterious as formerly. The various theories (as that of food, especially fish) that have been put forth lack general support.]

LUPUS ERYTHEMATOSUS.

Lupus Erythematosus.—Jenches,[2] after describing the general treatment which he had before employed in this case unsuccessfully, abandoned all external treatment and placed the patient upon a solution of phosphorus, according to the formula recommended by Bulkley,[3] as follows: Phosphorus, 6 gr.; absolute alcohol, 30 dr.; to be dissolved with the aid of heat and agitation, and then mixed, while still warm, with the following mixture, also warm: glycerol, 9½ oz.; alcohol, 1½ oz.; essence of peppermint, ½ oz. Each dram of this mixture contains $\frac{1}{20}$ gr. of phosphorus; of this 20 drops were first taken in water 3 times daily, after meals, the dose being gradually increased until at one time it reached 40 drops. A few weeks after the adoption of this remedy the burning and tenderness accompanying the skin-disease gradually disappeared. At the end of the second month the improvement was very noticeable, the dull red color previously so conspicuous fading. At the end of 5 months the improvement was so great that the patient considered himself cured. Thus, after several years of ineffectual external treatment, the disease had yielded to the internal employment of phosphorus. In administering phosphorus the action of the remedy upon the digestive organs should be carefully watched.

Sée[4] gives an excellent resume of our knowledge of this disease at the present time, and the article is replete with references to original literature on

[1] Abdruck. aus Dermat. Zeit., Bd. iii. [2] Boston M. and S. Jour., Nov. 28, 1895.
[3] In his article in the Am. Jour. of Med. Sci., Apr., 1893.
[4] Gaz. des Hôp., Oct. 12, 1895.

the subject. The name originally given to this disease by French observers as far back as 1828 was "erythema centrifugum," which was subsequently abandoned for the name now in common use given to it by Cazenave. The original description was that it was a spreading erythema tending to leave in the central area more or less atrophy of the skin. According to the writer, the disease has a chronic course, and is under the control of numerous influences which interfere with the peripheral circulation. The following varieties are referred to: 1. Erythematous; 2. Congestive, the "chilblain lupus" of Hutchinson; 3. Squamous, at times resembling certain forms of erythemato-squamous eczema; 4. Follicular or acneform, a variety which may pass into the deeper tissues, and may give rise to patches of almost cartilaginous induration, and thus approach in its general features "lupus vulgaris erythematoides" as described particularly by Leloir. The localities which the disease affects are considered: cases in which the face, scalp, and mucous membranes are affected are separated from those in which almost the whole body may be attacked, and which may run an acute course with a fatal issue. In discussing the diagnosis of this disease the writer calls attention to certain forms of superficial inflammation which occur in the course of tertiary syphilis which simulate lupus erythematosus very closely. In other cases lupus erythematosis may closely resemble superficial forms of lupus vulgaris. In describing the pathologic anatomy the entire absence of histologic or bacteriologic evidence of its direct dependence on the bacillus tuberculosis is confirmed. In considering the possible relations to tuberculosis the arguments that have been brought forward by those who regard this disease as being due to tubercular invasion, the evidence that has been advanced, are insufficient to establish the belief that lupus erythematosus is one of the tubercular manifestations, while, on the other hand, observations tend to show that it is due to a circulatory poison. Its relation to such circulatory disturbances as chilblain, heatblain, and Raynaud's disease is pointed out. The treatment recommended comprises both internal and local remedies. The internal use of phosphorus is recommended. During the active stage, that of spreading on the border, soothing remedies must be applied; later more active applications are tolerated and are advised. A resolvent plaster at night, followed by ointments containing resorcin, salicylic acid, or lactic acid, is recommended, as well as also scarification of the affected parts.

Malcolm Morris[1] at a meeting of the Dermatological Society of London exhibited a nurse, aged 46, with erythematous lupus which had followed the bites of mosquitoes. During a 6 months' residence in India she had been severely **bitten by mosquitoes** about the face and legs, which became inflamed in consequence. Some months later erythematous lupus began in the scar of a mosquito-bite on the side of the nose; a little later a patch started on the right cheek, and subsequently 3 more, all having the characteristic signs of the disease.

In a case of this disease in which other remedies have proved of no avail,

[1] Brit. Jour. of Dermat., Jan., 1896.

occurring in a woman 32 years of age, Legrain[1] employed **injections of sheep's serum successfully.** Two injections of 10 c.c. were employed at intervals of 5 days; 3 days after the first injection the spots began to grow pale, and 10 days after the second injection they had completely disappeared.

Lupus Erythematosus Disseminatus disappearing during Pregnancy.—Fordyce[2] records the case of a lady, aged 25, married 8 months, 6 months pregnant, always in good general health. Some months before marriage an erythematous lupus with much itching appeared on the face; 2 months after marriage, at the beginning of pregnancy, it showed itself also on the hands and arms. Shortly before delivery all evidences of the cutaneous disease had disappeared except the atrophic spots, which were surrounded by a pigmented zone. Another case of the same disease, which behaved in a similar manner during pregnancy, is referred to by the writer, but the disease recurred in a marked degree after delivery.

LUPUS VULGARIS.

Treatment.—Schultze[3] discusses especially the operation of **extirpation, followed by transplantation of skin** according to the Thiersch method. He summarizes his experience as follows: The radical operation in lupus of the face, with subsequent transplantation of skin, may be undertaken and carried out successfully. The same offers the greatest guarantee that the entire diseased skin will be removed; that the "combination treatment" recommended by Köhler is liable to be followed by relapses as readily as the treatment by the cautery or caustic ointments.

Sheild[4] showed a case of lupus vulgaris which he had successfully treated by **acid nitrate of mercury.** The patient, a woman 27 years of age, had suffered from lupus vulgaris of the nose for more than 4 years, and had undergone many scrapings. Acid nitrate of mercury, pure, had been applied on 6 occasions under cocain-anesthesia, with the result that the parts had healed over soundly, no trace of lupus tissue being now visible.

Branthomme[5] reports a case cured by the following method: Upon the upper part of the right hand and the lower part of the wrist was a lesion the size of a dollar, which had been treated unsuccessfully by various means for 14 months. Recourse was had to **potassium cantharidate,** a solution of which, prepared according to the following formula, was injected hypodermically: Cantharidate of potassa, 0.001 g.; hydrochlorate of cocain, 0.10 g.; distilled water, 10 g.; 1 c.cm. of this solution was given at each injection, and 8 injections were given in a period of 3 weeks. The injections were painful, and 1 was followed by abscess. The first 2 were followed by elevation of temperature—39.3° C. and 39° C.—and local reaction, which manifested itself by marked exudation. These phenomena did not appear at the third injection, but cicatrization then began and continued until a cure resulted.

[5] Ann. de Dermat. et de Syph., 1896, No. 1.

Ricketts[1] reports a case much benefited by **galvanism.** The injection of cocain may precede the operation, the latter consisting in the insertion of the galvanic needle in every direction through the diseased tissues, the operation being repeated until all evidence of redness has disappeared. The needle should extend through the integument, it not being necessary to attack anything beneath it. The writer believes that galvanism is to the lupus-bacillus what arsenic is to the cells of epithelioma. The chief objection to the treatment is the length of time required, which depends upon the area affected and the degree of tolerance on the part of the patient. With the use of cocain, however, the amount of galvanism used may be almost without limitation.

Serenine[2] has obtained good results in the treatment of this disease from the application of compresses saturated with pure beechwood **creasote** or with a 10 to 30% solution in glycerol or oil. The treatment possesses the great advantage of being easily carried out and of preventing much scarring. It is, however, slow in its action, and does not prevent relapses.

An Oidium in the Skin of a Case of Pseudolupus Vulgaris.—Gilchrist and Stokes[3] report in detail a case occurring upon the face in a man of 33 in which the disease of the skin resembled lupus vulgaris more than any other disease. Stained specimens showed an hypertrophy of the epidermis, throughout which numerous variously-sized, well-defined miliary abscesses were disseminated. Elsewhere the epidermis was considerably infiltrated with polynuclear leukocytes. Large collections of granulation-cells were massed in the corium, and a few miliary abscesses were noted in the upper portion of the cutis. In all the miliary abscesses, and also among the granulation-cells in the corium, were numbers of doubly-contoured, refractive, round and ovoid bodies, varying in size from 10 μ to 20 μ in diameter, many of them with buds and others with vacuoles. They were arranged singly or in groups, contained granular protoplasm, and simulated very closely blastomycetes. No tubercle-bacilli could be found. The writers conclude that this extensive cutaneous disease was caused by the presence and growth in the tissues of a species of oidium, and that this is the only example in literature of a pure cutaneous disease which has been shown to be caused by a species of oidium, and the third example in which lesions of the human skin have been produced by organisms allied to the yeast fungi, Busse's case and Gilchrist's case being the other 2.

Tuberculosis of the Skin and Cutaneous Manifestations occurring in Scrofulous Subjects.—Noyes[4] considers the subject in two groups: in the first the diseases of the skin are directly due to the influence of the tubercle-bacillus. In this group are found lupus vulgaris, scrofuloderma, verruca necrogenica, acute tubercular ulceration, and tubercular lymphangitis. Group 2 comprises lesions occurring in scrofulous subjects which are predisposed to this disease by a certain peculiarity of tissue, but are not proved to be due to the direct action of the tubercle-bacillus. Here are arranged erythema induratum (Bazin), lichen scrofulosorum, scrofulous pustuloderma (acne scrof-

[1] Jour. Am. Med. Assoc., Jan. 18, 1896.
[2] La Sem. méd., 1895, vol. xv. p. 198.
[3] Bull. of Johns Hopkins Hosp., July, 1896.
[4] Intercol. Med. Jour., Apr. 20, 1896.

ulosorum, etc.). In lupus vulgaris the elementary lesion is situated deep in the corium, and consists of giant, lymphoid, and formative cells in a fibrocellular reticulum. All the structures that are found in miliary tubercle are present in lupus. Bacilli are found in the histologic elements just described which differ in no way morphologically from tubercle-bacilli. They exist in very small numbers and are found with the greatest difficulty, but in spite of their sparse distribution they are capable of setting up generalized tuberculosis in susceptible animals. On clinical grounds there is very strong evidence of the identity of the organism which produces the pathologic processes in lupus and phthisis. Many cases of direct and indirect inoculation are recorded where phthisical patients have transferred the disease in the form of lupus vulgaris. In Australia lupus vulgaris is much rarer and less severe than in England. Noyes would account for the comparative rarity of true lupus vulgaris and for its milder type in Australia by—1. The greater exposure of its inhabitants to direct sunlight; 2. The absence of tendency to hyperemia and stagnation in exposed parts due to the effect of cold; 3. Increased tissue-resistance. It is true that lupus is no respecter of persons, so far as the rich and the poor are concerned, but it is also true that it assumes a much more severe type amongst the poor, half-starved, ill-nourished individuals so common in the largest cities of Europe and so rare in the cities of Australia.

By scrofuloderma is meant a suppurating dermatitis which occurs in scrofulous individuals, attacking the skin either in connection with more deeply-seated lesions, as strumous glands or tubercular processes in bone or joints, or independently of any underlying tubercular lesions. Verruca necrogenica, anatomical tubercle, tuberculosis verrucosa cutis (Riehl and Paltauf), and lupus verrucosus are all bacteriologically and histologically identical. Verruca necrogenica occurs for the most part, but not always, on the hands of those who handle animal tissue in which the tubercle-bacillus exists—pathologists, butchers, and cooks.

Acute tubercular ulceration is observed only in advanced cases of pulmonary or intestinal tuberculosis. The ulcer is irregular in shape and covered with granulations of a yellow color. It usually occurs about the oral or anal orifice, occasionally elsewhere. It is very intractable, and not infrequently spreads beyond the original limits. The cause is an autoinoculation. The tubercle-bacillus can be demonstrated. Tubercular lymphangitis is a rare condition in which the tubercle-bacillus would seem to find its culture media in the lymphatic vascular trunks. More or less impediment to the flow of lymph takes place, with consequent elephantiasis of the part. Nodules with a pink, dusky red, or violaceous color occur in the course of the affected lymphatics. They ulcerate and discharge their contents in the form of a purulent-looking matter. Sometimes lymph is discharged in which the bacillus may be found.

Whether the tubercle-bacillus has any direct action in the production of the nodules of erythema induratum of the scrofulous is a point not yet settled. Under the head of "scrofulous pustuloderma" Noyes includes many pustular affections occurring in scrofulous subjects. He thinks they are possibly all

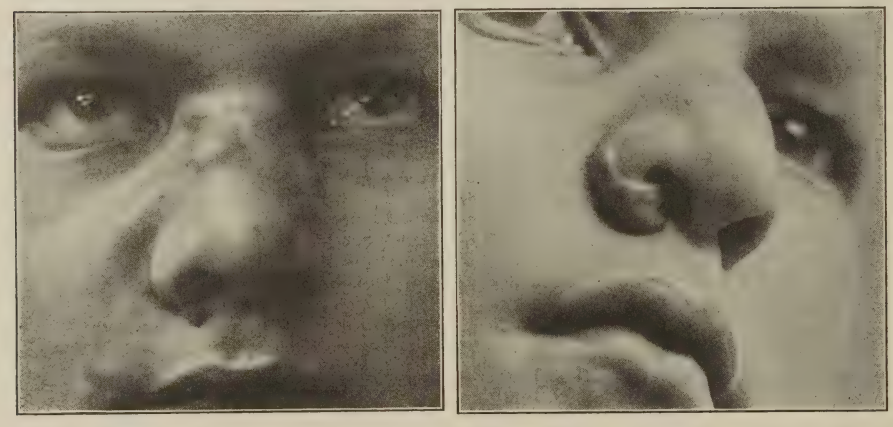
phases of one and the same process, though differing in detail. They all have these points in common: The lesions are eventually pustular; they occur in connection with the follicles of the skin, are more or less violaceous in color, leave scars, and are observed in scrofulous subjects.

Case of Blastomycetic Dermatitis in Man.—Gilchrist[1] describes the histopathology of a section of skin taken from a case which was under the care of Dr. Duhring, by whom it was diagnosed clinically as a typical example of chronic scrofuloderma of the back of the hand. Gilchrist was unable to demonstrate in the tissues the presence of the tubercle-bacillus. Numerous curious bodies were found distributed here and there throughout all the sections. They presented all the appearances of parasites. The surface of the sections of skin was very irregular, showed well-marked prominences and depressions, and was covered with irregular masses of detritus, which consisted of small collections of pus, detached epithelial cells, fibrin, coagulated albumin, and comparatively large masses of red blood-corpuscles. The stratum corneum was well marked and was infiltrated with small collections of pus, while scattered about were numerous polynuclear leukocytes. This layer was separated in places from the subjacent epithelium by a similar inflammatory deposit. It was in the mucous layer, however, that the chief pathological changes were observed. The epithelium was enormously hypertrophied. The most noticeable feature in the mucous layer was the presence of numerous well-defined miliary abscesses of different sizes. The contents consisted of polynuclear leukocytes, nuclear detritus, a few detached epithelial cells, now and then a giant-cell, a number of peculiar nuclear cells, and the peculiar organisms which characterize this disease. These organisms, which appeared to have a causal connection with this disease, were almost always present in the miliary abscesses and scattered throughout the corium, but none were found on the surface of the skin. They were always surrounded by inflammatory material. The number present varied, as many as 15 having been found in one abscess, though the average was only 4 to 6. They were observed usually in pairs of unequal size or sometimes in small groups. They consisted of a capsule, a light peripheral zone, protoplasm, and a vacuole. That the organisms are certainly not the results of any form of degeneration of epithelial cells is clear for the following reasons: 1. They were found in the corium as well as in the epidermis; 2. They were always surrounded by inflammatory material wherever they were found, especially in the miliary abscesses; 3. Their reproduction was carried on by gemmation; 4. They were much smaller than epithelial cells, approaching more nearly the size of the nucleus of these cells; 5. They were never found intracellular (*i. e.* with reference to epithelial cells) or intranuclear; 6. They were often found enclosed in giant-cells in the abscesses and in the corium; 7. They had in the adult form certain constant characteristics—namely, a well-defined capsule, a clear space between it and the protoplasm, and a well-marked vacuole; 8. The occurrence in the same sections of so many altered epithelial cells rendered comparison easy and brought out the

[1] Johns Hopkins Hosp. Rep., vol. i.

marked differences which exist between these and the bodies in question; 9. Treatment with caustic potash showed them to be resistant bodies having a double contour. The main characteristics of the organism, especially in its mode of reproduction by gemmation and its comparatively small size, point unmistakably to a classification among the yeasts or blastomycetes.

Two Cases of Protozoan (Coccidioidal) Infection of the Skin and other Organs.—Rixford and Gilchrist[1] contribute elaborate and important articles, with exhaustive pathologic research, on the subject. The first patient was a man aged 40, a native of Fayal, Azores, who went to California in 1886 as a laborer, at which date the disease of the skin began in the form of a large sore 2½ by 5 in. on the back of the neck, and also probably one on the forehead. There was no history of syphilis or tuberculosis. The leading points of the case may be summed up as follows: The disease was one of fatal general protozoan (coccidioidal) infection, which remained localized on the back of the neck for 5 or 6 years, when other similar lesions appeared on the eyebrows, nose, cheek, ear, and back of the right hand. On various occasions exacerbation occurred. The lesions remained localized to the skin for 8 or 9 years before the neighboring lymphatic glands became involved, up to which period the patient's general health continued good. The character of the cutaneous lesions resembled somewhat closely those of tuberculosis cutis. Following the infection of the lymphatic glands the temperature began to rise (102–103° F.) and assumed an intermittent character, the general health now becoming impaired. Both eyes were destroyed by extension of the disease from the eyebrows. The internal organs affected, as shown by the autopsy, were the lungs and pleura, the adrenals, testes, epididymes, seminal vesicles, prostate, and lymphatics following the vas deferens, the surface of the liver, the spleen, the peritoneal surface of the diaphragm, the peritoneum, the lymphatic glands, and even the bone-tissue. The entire alimentary canal and mesenteric glands remained practically normal throughout the course of the disease. There was a close resemblance, amounting even to histologic identity, between many of the nodules produced by the protozoa in the lungs and other internal organs and genuine tubercles. Both to the naked eye and microscopically the nodules were indistinguishable from tubercles, except that they contained the protozoan organisms and did not contain tubercle-bacilli. These lesions therefore fall into the group of pseudotuberculosis. The organisms found were spherical, unicellular bodies, and consisted (in the incapsulated condition) of a thick, doubly-contoured capsule which enclosed a finely granular protoplasm. The parasites developed by sporulation, and often as many as 100 small spores or sporozoites were set free by the bursting of the capsule. No nucleus could be demonstrated. The parasites were found both intracellular and, as a rule, extracellular. Some of the inoculation-experiments in animals were successful. Photographs from life of the patient, as well as numerous photomicrographs of the parasites, in situ and isolated, accompany the report.



The second case occurred in a man aged 33, who, as in the first case, was a

[1] Johns Hopkins Hosp. Rep., vol. i.

native of the Azores and who resided in California. According to his statement, an attack of hematemesis was followed 4 weeks later by an eruption on the left side of the forehead of two papules, which rapidly increased in size. Other skin-lesions appeared on the face, scalp, trunk, and arms to the number of 30; most of these lesions presented clinical appearances similar to those noted in Case 1, except that there was an absence of fungating masses. Six weeks later the urine showed blood, according to the patient's statement. Two months after the first eruption appeared the lymphatic glands of the neck became implicated. No pulmonary symptoms developed. The weakness increased rapidly and the patient suffered from insomnia and night-sweats. The urine at this stage was normal. In watching the eruption fresh spots were seen to appear as papules, which became capped by small vesicles and then became crusted; in this way a small ulcer was formed with somewhat undermined edges and a base which consisted of uniformly enlarged papillæ. The patient died 12 weeks after the appearance of the first skin-lesion. There was no autopsy, but a portion of skin was removed from a patch over the clavicle, and the section revealed some very interesting features. In the epidermis were numerous well-defined, variously-sized miliary abscesses which contained protozoa. The upper part of the corium only was affected, in the form of an extremely acute inflammatory exudation which displaced the normal structure. Protozoa were found in abundance in the corium among the inflammatory products near the vessels, and particularly throughout the central portion of the ulcer. One section showed the middle of the ulcer so full of these large protozoa that the microscopic field hardly consisted of anything else. Giant-cells were almost entirely absent. The protozoa, although at first appearance they were similar to those found in Case 1, differed from them mainly in this respect, that whereas the pathological changes caused by their presence in Case 1 were of a chronic character, in Case 2 they had given rise to a process which was distinctly acute. Their mode of development was practically the same in both instances; those in Case 2 were generally larger. The sporulation forms, particularly those in which the capsule was just about to rupture or had just ruptured, were very numerous, whereas in Case 1 they were found only after some searching. Another special feature of the second variety of protozoan was the presence of a well-defined space or vacuole situated in the centre of the organism, which was seen in the adult encysted protozoon, and could be observed in nearly all the stages of its development into sporozoites. Considering the enormous number of protozoa, and particularly of free sporozoites, present in every diseased area, one cannot see how such a patient could escape general infection. Photographs of the patient from life, sections of the skin, and illustrations of the protozoa in different stages of development, in situ and isolated, are given. [These cases are of great interest, and open up a new field in histopathology. Not only were the clinical features, it would seem, *sui generis*, differing from known forms of tuberculosis cutis, scrofuloderma, lupus, and other allied clinical forms of disease, but the discoveries render the disease probably a new one. Considering the great numbers

of the protozoa and their peculiar forms, it is not likely they would escape detection by skilled microscopists. We have had the opportunity of examining sections showing the protozoa found.]

Case of Rhinoscleroma originating in the United States.—Wende[1] reports a case of rhinoscleroma occurring in the person of a boy, 11 years of age, born in the United States of American parents. The family history was good and he was apparently robust. The disease had existed $1\frac{1}{2}$ years, and was progressive in its nature. It began as a pink spot below the right naris, and was free from pain. At the end of 3 months it was perceptibly elevated, and had developed into a pronounced ridge, which gradually extended to the left side of the nose. The lesion was superficial, but the underlying tissue was infiltrated and was very hard. Upon the right side of the nose were two sharply-defined ridges measuring about $1\frac{3}{4}$ in. in length, having between them a small area of sound skin. Upon the left side of the nose was a single ridge having a uniform width of nearly $\frac{1}{2}$ in. The right ala was uniformly thickened, causing a narrowing of the opening of the nostrils (see Figs. 165, 166). The result of the bacteriologic examination was still in doubt at the time of the report.

FIGS. 165, 166.—Rhinoscleroma (Wende).

Freudenthal[2] also records a case (with photograph) of the same disease occurring in a Polish Jew, the lesion, occupying the dorsum of the nose, being at first mistaken for a syphilitic gummatous infiltration. The bacillus was found by Buxton, and, as in other instances by other bacteriologists, the resemblance to Friedländer's pneumococcus was noted.

FOLLICULAR AND GLANDULAR DISEASES.

Keratosis Follicularis (Psorospermose Folliculaire Vegetante of Darier).—Bowen[3] gives notes of a new case of this rare dermatosis. [The first cases were described almost simultaneously by Darier and White about 7

[1] Jour. of Cut. and Gen.-urin. Dis., Mar., 1896. [2] N. Y. Med. Jour., Feb. 1, 1869.
[3] Jour. of Cut. and Gen.-urin. Dis., June, 1896.

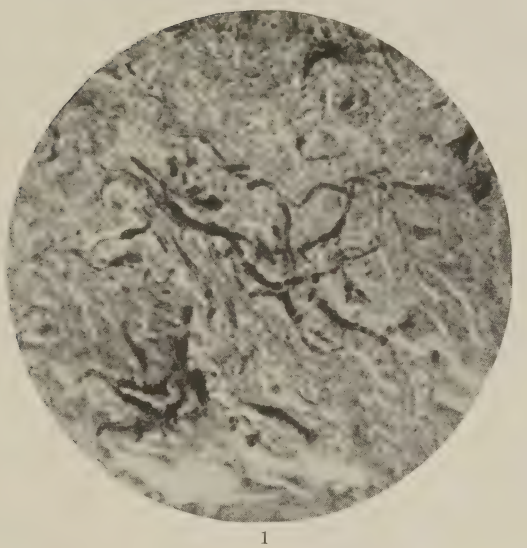
years ago, since which date about 20 cases have been recorded, contributed by French, German, Norwegian, and American observers; 4 cases have been observed in America.] Bowen's case was a woman 29 years of age, living near Boston, fairly nourished, and of a swarthy complexion. The face had an aspect characteristic of the disease. It was covered with lesions that did not vary much in color from that of the normal skin, although there was a distinct darkening of the skin as a whole, which looked coarse, furrowed, and greasy. The individual lesions consisted of small, greasy-looking papules, on an average the size of a pin's head. The center of each papule contained a fatty-looking mass or plug. In some the tip of the lesion showed a minute pustule instead of the greasy plug. To the finger the sensation was that of a nutmeg-grater. Upon the trunk the parts especially affected were the sternal, interscapular, and sacral regions and the median line of the abdomen from umbilicus to pubes. Here the lesions were numerous and closely aggregated. They were dark and greasy-looking, and were less elevated than those on the face. Some of them bore a strong resemblance to keratosis pilaris. The labia majora were the seat of prominent lesions, some of them the size of a large pea, while through the confluence of the lesions the labia had become much thickened and papillomatous. Close inspection showed that the greater number of the lesions were grouped about the follicular orifices; in other words, that the affection was essentially a follicular one.

Bowen thinks it probable that it always begins early in life. Of the 20 cases collected, 13 were males and 7 females. The disease is one of the most obstinate of known dermatoses. No one has been able to record a cure. The point upon which there has been much diversity of opinion is whether the lesions are essentially follicular or not. White, whose first case was published before Darier's article had appeared, named the disease keratosis follicularis, and stated that at the beginning of the process the lesions were in no way to be distinguished from those of simple keratosis pilaris. Boeck and most of the other writers have been unable to determine that the lesions were confined to the follicles. Bowen is inclined to adhere to his and White's original position —namely, that the process is primarily and essentially a keratosis of the mouths of the follicles. Both clinically and histologically the disease appears to resemble the anomalies of development, as exemplified by ichthyosis, more closely than any other group.

Pityriasis Rubra Pilaris (Devergie).—West and Liddell[1] both report cases of this rare disease. In the case of West arsenic was tried in full doses for several weeks without any improvement; the administration of thyroid extract, however, was quickly followed by relief of the symptoms to such an extent that at the end of 5 weeks the patient was reported to have been in excellent health and on the way to complete recovery. Dr. Liddell's case greatly improved under the use of sulphur baths at Harrogate and the application of resorcin ointment, with the subsequent use of a salicylic and creasote ointment. A study of the histopathology of the disease showed that the hairs were greatly

[1] Brit. Jour. of Dermat., Sept. 18, 1895.

changed, mainly by an increased keratinization of the outer root-sheath, causing a thickening of the hair and also of the lower portion of the follicle. There was general atrophy of the sweat-glands, including obstruction of the lumina and wasting of the cells in the coils. The muscles of the hairs were also atrophic.



Keratosis Universalis Multiformis (Pityriasis Pilaris Rubra of Besnier, Lichen Ruber Acuminatus of Kaposi).—Lewin,[1] after making an exhaustive and critical study of this much-vexed disease, especially as concerns the identity of the disease to which Besnier and other competent French observers have given the name pityriasis pilaris rubra, and Kaposi lichen ruber acuminatus, comes to the following conclusion: That the disease called pityriasis pilaris by French observers is not a new disease, but has been before described with other names by several writers, as also has the lichen ruber acuminatus described by Kaposi. The lichen ruber of Hebra is a disease which, without the employment for its cure of arsenic, is absolutely fatal, but by its use is a curable disease. The name pityriasis pilaris is equally unjustifiable with that of lichen ruber acuminatus, inasmuch as both are keratoses, and may with as much right as the various other phases of keratosis be so called, and this particular form be designated with the name "keratosis universalis multiformis." In favor of the keratosic process the increase of the keratohyalin and the decrease of the eleidin, as well as the other clinical features, speak. The decrease of the urea and the increase of uric acid in the urine, the presence of hippuric acid in the cutaneous crusts, and their relation to keratosis are possibly due to increased consumption of oxygen in the augmented formation of epidermis.

Unique Case of Agminate Folliculitis of Parasitic Origin.—Hartzell[2] reports an unusual case of folliculitis due to the invasion of the follicles of the skin by the trichophyton or a very similar fungus. The patient was a man of 38, in the employ of a railroad company as a repairer of signals; 5 or 6 weeks before coming under observation a few small pustules on the inner side of the left leg just above the internal malleolus appeared. Through the implication of adjacent follicles these rapidly grew into a palm-sized patch elevated $\frac{1}{8}$ in. above the surrounding healthy parts. Other patches of a similar kind appeared upon various parts of the leg, and these continued to enlarge and to coalesce until they covered at least two-thirds of the surface of the leg (see Plate 20, Fig. 2). Marked pain attended the eruption, so that the patient was compelled to give up his work for a considerable time, being unable to walk. Microscopic examination of excised portions showed marked inflammatory changes in and about the follicles, and, what was most interesting, an abundance of spores and mycelium, the latter being especially plentiful (Plate 20, Fig. 1). Under the use of a sulphur ointment, 1 dram to the ounce, improvement was immediate and a cure followed within a few weeks. [The case illustrates a very rare form of disease, one whose nature would probably never

[1] Berl. klin. Woch., Sept. 16 and 23, 1895.

FIG. 1.—Mycelium in follicle (Hartzell). FIG. 2.—Dr. M. B. Hartzell's case of agminate folliculitis.

have been explained without the removal of a section of skin from the living subject and the use of the microscope. It demonstrates, moreover, that the trichophyton fungus is capable of setting up still another form of follicular and cutaneous inflammation, the list having been considerably enlarged of late.]

Case of Undescribed Papuloulcerative, Follicular, Hyphomycetic Disease of the Skin.—Under this title Duhring and Hartzell[1] report an undescribed form of mycosis of the skin. The patient was a boy of 15, employed in a mill. Upon the sides of the neck were patches of chronically inflamed, papulo-ulcerative, slightly crusted lesions. The disease, which had existed for 3 years, had produced slight whitish, pitted, irregularly-shaped scars. It resembled a mild expression of lupus vulgaris verrucosus more than any other disease. There was no resemblance to tinea circinata nor to tinea sycosis. A microscopic examination of several of the excised lesions disclosed the presence of spores and mycelium resembling in a general way the common trichophyton fungus of ringworm of the scalp and general surface, except that they were much larger. The fungus was found in cavities occupying the site of hair-follicles.

Etiology and Histopathology of Parasitic Sycosis.—Ullmann[2] has studied 8 cases of parasitic sycosis, the results coinciding with those of Sabouraud as to the existence of an ectotrichial form of trichophytosis, in which the fungus remains in the hair-sheath and does not enter the hair-substance. The various degrees of virulence of the fungus, the sensitiveness of individual skins, age, race, locality, reaction of the sweat, and cleanliness or neglect of the skin are sufficient to explain the intensity of the process and the extent of the cutaneous disease. In the cases examined the fungus, in all except 1, was that described by Sabouraud as "tricophyton mégalasporon pyogène du cheval à culture blanche;" in 2 of the cases staphylococci were also present. One case possessed all the clinical features of impetigo contagiosa, and was so diagnosed until the microscope showed the trichophyton; from which it is believed that one variety of impetigo may be due to this fungus, and another to staphylococci.

Changes of an inflammatory character were found around the hair-follicle, due probably to the action of toxins produced by the fungus. At first there occurs a perifolliculitis, with mononuclear, and later polynuclear, leukocytes, which penetrate the internal and external root-sheaths, the follicle becoming enlarged, the walls thinned and ultimately obliterated. With suppuration of the follicle the hair falls out and the sebaceous glands are destroyed. Attention is directed to two notable features in the process, one being the effects produced at a considerable distance from the fungus in the follicle, explicable only by the theory that the fungus forms a toxin which sets up inflammation in the tissues about the follicle; the other is the existence of giant-cells.

Etiology of Acne.—Lomry,[3] after a bacteriologic examination of the lesions of pustular acne and of comedo, finds that the staphylococcus pyogenes

[1] Am. Jour. of Med. Sci., Mar., 1895. [2] Wien. klin. Woch., Nos. 18–20, 1896.
[3] Dermat. Zeit., Bd. iii. H. 4.

albus is constantly present in the pustules of acne. There is also occasionally present, always in small numbers, a yeast-fungus and a small bacillus. In ordinary comedo, unaccompanied by inflammation, microbes are present in abundance, the staphylococcus albus being always at hand, but not to such a degree as in pustular acne. When inflammation occurs in comedo a diminution in the number of kinds of microbic organisms takes place. The presence of certain microbes, however, does not explain the occurrence of the disease, for the skin of persons who are free of acne shows microbes as abundantly as those who are affected with acne. The staphylococcus, being met with in many other diseases of the skin, cannot be regarded as the specific cause of the acne. A suitable soil must be provided. The author is of opinion that Unna's special bacillus is a mild variety of the bacterium coli, and that the contrast of acne with other diseases of the skin with staphylococci may be accounted for by a difference in the virulence of the microbes.

Massage in the Treatment of Acne of the Face.—Pospelow[1] calls attention to the good results which he has obtained from massage of the skin of the face in the treatment of acne in this region. By this means the lessened tone of the skin, and especially of the sebaceous glands, is increased, and the thickened sebaceous matter expressed from the ducts. The rubbing should not be done without method, and should follow the direction of the gland-ducts and the muscle-fibers of the skin in order that the sebum may be expressed from the glands. It should be employed for 10 minutes, morning and evening, for several months, until the tone of the skin is restored and the openings of the ducts have returned to their normal size.

Alcohol in the Treatment of Acne Rosacea.—Abraham[2] recommends a treatment which was only employed in the first two grades, and was successful; it was, moreover, free from all objectionable features. It consists in the employment of 95% alcohol for local subcutaneous injections. The immediate effect of the injection is a swelling and anemia of the area subjected to it. This condition lasts but a few moments, the next occurrence being an increased redness of the same part of the skin subjected to treatment. This redness lasts from a ½ hour to 3 or 4 hours; thereafter it gradually disappears, the treated skin area assuming its usual color. The dilated blood-vessels and papules will be found after repeated injections to undergo sure but slow obliteration, until finally the whole lesion disappears and the affected integument appears greatly improved or normal. The treatment in some cases lasts 8 or 10 weeks; in others a great deal longer. A clean hypodermic syringe with a thin needle is needed. The syringe is filled with 20 or 30 drops of alcohol, 95% strength. The part of the nose or cheek selected to be operated on is pinched up and the injection made. Not more than 30 drops of the fluid are required, nor more than 3 injections a week. By being aseptic there will be no inflammation, and in the absence of it the remedy can be applied to the same place repeatedly until the desired result—a cure—is attained. The first form of rosacea, in which hyperemia of the skin is the

[1] Dermat. Zeit., Bd. ii. H. 3.

[2] Am. Med.-Surg. Bull., May 16, 1896.

main and only lesion, is the most amenable to this treatment. The second grade requires greater perseverance, on account of the papules and pustules present. Both grades, however, tolerate it well. This method of treatment is not put forth as a specific, but the reporter has had uniform success in his cases, and the cleanliness and convenience that this treatment in a measure offers alike to physician and patient certainly entitle it to consideration and trial. The histories of 6 cases which were cured are given.

On the Topical Treatment of Acne.—Bronson,[1] after discussing the bacteriologic aspect of the disease and its general pathology, states that the prime indications for its treatment are—1. Reduction of the hyperkeratosis; 2. Removal of the comedones; 3. Disinfection of the follicles; and, finally, the employment of such local or general antiphlogistic measures as the case may require. Of these objects, the first two are accomplished by mechanic means, the first three by topical measures, while the last may require both topical and general treatment. The curet is an indispensable implement in the management of the disease, Dr. Bronson preferring an elongated olive-shaped instrument with a large fenestra, that is easily cleaned, and the edges, which are but slightly curved, are sharp. Those in common use are too small. The skin is put on the stretch, and the edge is then swept with rapid free-hand strokes over the affected surface, with the effect of planing off the cutaneous elevations, and also of clipping off the summits of many pustules and removing at once the horny cap that seals the orifices of the distended sebaceous follicles. By this means is accomplished in an instant what would be less thoroughly effected by applications of salves, soaps, hot water, or steam for days or weeks. In addition, when comedo exists each follicle must be treated separately by the use of the comedo-extractor or presses, for which purpose the curet described answers the purpose. In refractory cases, in which the comedones are dry and the horny layer of the skin dense, a preparation composed of vinegar 2 parts, glycerol 3 parts, and kaolin 4 parts may first be applied. After the mechanic treatment has been thoroughly carried out at one or more sittings disinfection is to be practised, the skin being bathed with a 1 : 1000 solution of mercuric chlorid or a 1% soap. If there are many pustules, he uses solution of hydrogen dioxid before the sublimate wash is applied. For the home treatment sulphur and resorcin are relied upon. The compound zinc-sulphid lotion (1 dram each of potassium sulphid and zinc sulphate to 4 oz. of water) is highly esteemed; resorcin is used as an aqueous or alcoholic 3 or 4% lotion.

During the course of the mechanic treatment Lassar's zinc-starch-petrolatum paste should be applied at night as an antiphlogistic remedy, and rubbed off in the morning with petrolatum. Simple dusting powders are also valuable. [The article deals with the local treatment only, and may be regarded as a plan of therapeusis based upon the pathology and bacteriology of the disease. No mention is made of the varieties of acne against which the methods suggested are particularly applicable. The skin is treated vigorously and not

[1] N. Y. Med. Jour., Mar. 28, 1896.

spared by this method. No discrimination is made by the writer between the several anatomic, etiologic, and pathologic varieties of the disease.]

Adenoma Sebaceum with Mollusca Fibrosa.—The case reported by Anderson[1] occurred in a male, was noncongenital, was not associated with dyspepsia or telangiectasis, and the patient's intellectual condition was not deficient. The adenomata began to appear at the age of 7, and several years later small fibrous tumors appeared on the body. They were treated successfully by excision.

A New Treatment of Hyperidrosis.—Frank,[2] after considering the treatment of this affection by various other means, including the chlorated combinations with ether and the preparations of methylic acid, calls attention to the value of formalin in from 10 to 20% alcoholic solution, which usually cures hyperidrosis very promptly. He has made use of tannoform (a powder consisting of formalin and tannin) very successfully in about 50 cases, especially in bromidrosis of the feet.

Treatment of Hyperidrosis.—M. L. Hensner[3] recommends the following wash, applied by means of a cotton tampon for local conditions and in the form of a spray for generalized sweating: Balsam of Peru, 15 gr.; formic acid, 75 gr.; chloral, 75 gr.; alcohol, 1 oz. In refractory localized forms the wash may be doubled, and 15 gr. of trichloracetic acid may be added.

DISEASES OF THE HAIR AND NAILS.

Change of Color of the Hair from White to Black, due to Exposure to Cold and Exhaustion.—Griffiths[4] reports the case of a man of 65, an engineer in a city fire department, in whom, after prolonged exposure to cold and consequent great exhaustion, the hair turned from white to black within a few hours. The change in color was not due to any foreign matter (such as smoke or soot), since repeated washings were without effect.

Two Cases of Piedra Nostras.—Unna[5] describes 2 cases of this disease, which is rarely encountered in Europe. The fungus is saprophytic on the hair and does not enter the interior. Sections of the hair showed a dense collection of round, ovoid spores, looking as if stuck on the hair. In both cases the fungus was cultivated. In 1 the spores and hyphæ were smaller and finer than in the other. In a case of true Columbian piedra, fungus of a very large-spored variety was found.

Pityriasis Alba Atrophicans.—Krösing[6] reports a case of this very rare affection. The subject was a man 40 years of age, in good general health, without history of inherited tendency to cutaneous disease. The alterations in the skin occurred on both lower extremities and were symmetrical. Around the ankles the skin was livid, thin, tightly stretched, and covered with variously sized, grayish-white, shining, for the most part adherent, scales. Owing to the stretching of the skin, the natural marking had disappeared, and it was no

[6] Dermat. Zeit., 1896, Bd. iii. H. 1.

longer possible to pinch it up in folds. The subcutaneous fat was also atrophied, and the skin seemed to lie closely upon the tendons and bone. Movements of the foot were hindered by the tightness of the skin. The venous network was clearly visible through the thin skin. Upon the leg the scales were more delicate, thinner, bran-like, and less firmly adherent, so that they could be in great part removed with the hand. The muscles of the calf were also diminished in volume. In the hollow of the knee the skin was tightly stretched, so that extension of the leg was accomplished with difficulty. Upon the thigh the changes were less marked and were of more recent origin. On both sides the affection reached in front to the groin, behind to the lower border of the gluteal muscles. Sensibility, patellar reflex, and electrical excitability were normal. The disease began when the patient was 13 years of age on the left ankle, with the appearance of a dry, scaling, pale spot which burned slightly rather than itched. This spot had never been reddened, swollen, or moist, nor had any other change in the skin, as papules or vesicles, preceded the scales. The scaling gradually extended over the entire lower extremity. The disease did not begin upon both extremities at the same time, the left one having been affected 10 years before the right one. Histological examination of excised portions of the altered skin showed marked atrophy of all parts, but no evidences of inflammatory change. [The name given to the disease by the reporter indicates sufficiently the principal clinical features of this extremely rare dermatosis, which is at present practically unknown in the United States. It probably belongs to the group of diseases of which Buchwald's and Bronson's cases of cutaneous atrophy, and also morphea, are notable examples.]

Bacteriologic Investigation of a Case of Trichorrhexis Nodosa Barbæ.—Essen[1] gives the following as the result of the investigation of a case of trichorrhexis nodosa of the beard: 1. A small, well-characterized bacillus was found almost constantly in all the diseased hairs; 2. This bacillus differed essentially from that described by Hodara as the "bacillus multiformis trichorrhexidis," and has not yet been described; 3. Upon normal hairs and in 3 cases of trichorrhexis capillitii this bacillus was not found; 4. Inoculations practised with pure cultures of this bacillus upon normal hairs of the beard led to the development of a disease-picture identical with the original case; 5. Therefore it is in the highest degree probable that the bacillus in question can produce trichorrhexis nodosa, but the final proof will only be afforded when the vitality of the inoculated bacillus in the secondarily produced trichorrhexis has been demonstrated.

Treatment of Onychomycosis with Pyrogallic-acid Ointment.—This disease, as is well known, is extremely difficult to cure. Dubreuilh[2] has used Pellizari's method of treatment, which resulted in a complete cure in 5 cases. The nail and surrounding tissue are smeared twice daily with an ointment composed of equal parts of pyrogallic acid and olive oil. When the tis-

[1] Arch. f. Dermat. u. Syph., 1895, Bd. xxxiii. H. 3.

[2] Monatsh. f. prakt. Dermat., Bd. xxii., Feb., 1896.

sues around the nail have become acutely inflamed, the epidermis darkly discolored and raised up by pus, and the nail movable, the ointment is discontinued, the parts cleansed, the pus removed, and the ends of the fingers bandaged with antiseptic remedies twice daily. In a few days the blackened nail falls off spontaneously, and is in time replaced by a new nail.

Sabouraud [1] employs another mode of treatment for the same disease. Each finger is bandaged with absorbent cotton saturated with the following liquid: Iodin gr. 15; potassium iodid gr. 30; distilled water 1 quart. The bandage is maintained in position by a rubber finger-stall. After about 4 months of treatment the diseased part of the nails was observed to be divided from the healthy part by a transverse line, the growth of the cryptogam being arrested. The method is considered superior to evulsion and the production of an artificial paronychia.

THERAPEUTICS.

Diet in the Etiology and Treatment of Diseases of the Skin.—In a paper read before the British Medical Association, Walter G. Smith [2] presents the following conclusions upon this subject: (1) Very few skin diseases are directly traceable to dietetic causes, but improper diet may aggravate existing eruptions. Idiosyncrasy must be largely allowed for. (2) The diseases that may so arise are of a transitory character, and mostly belong to the class of erythemata. (3) Diet has very little influence in promoting the cure of cutaneous eruptions. The results are far behind popular expectations, even in such cases as acne rosacea, where we are led to hope for much. (4) Avoidance of alcohol, regulation of the bowels, and the cure of anemia are of infinitely greater importance than special dieting in the management of diseases of the skin. [In this country there are many able and experienced dermatologists who differ from Dr. Smith in his estimate of the value of a regulated or special diet in the treatment of many inflammatory diseases, especially eczema.] The same subject is also considered very fully by Brocq,[3] who from his investigations arrives at the conclusion that there is no exclusive diet for those with cutaneous diseases. It is only after having made a minute examination of the disease, then, of the idiosyncrasies of the patient, his constitution, his morbid tendencies, his mode of life, of his race, and the climate in which he lives, that one can prescribe his diet.

A New Lotion for Dry Itching Inflammatory Diseases.—Boeck [4] recommends the following formula: Talc and starch, of each 50; glycerol, 20; lead-water, 100. The bottle containing the mixture is to be well shaken; the lotion is diluted with twice the volume of water, and applied to the affected parts with a brush or mop, after which the region is left uncovered until the lotion has completely dried, leaving on the skin a thin coating of powder. A cooling, antipruriginous, astringent, and antiseptic action results.

[1] Ann. de Dermat. et de Syph., Jan., 1896. [2] Brit. Jour. of Dermat., Oct., 1895.
[3] Beit. z. Dermat. u. Syph., Festschr. Lewin., Berlin, 1896.
[4] Monatsh. f. prakt. Dermat., Bd. xxi. No. 3, Aug. 1, 1895.

In cases of very tender skin half of the lead-water in the above formula may be replaced by the same quantity of a 1 % boric-acid solution. The lotion is recommended in dry dermatoses, especially in acute papular eczema, chronic eczema, eczema of the genital and anal region, lichen, and psoriasis of inflammatory type. It is contraindicated in diseases accompanied by a fluid discharge.

Potassium Permanganate in the Local Treatment of Diseases of the Skin.—Bulkley[1] has found this drug, employed as a wash, 1 to 2 % strength, useful in a considerable number of cases of eczema, and also to some extent in other diseases characterized by itching. The solution is brushed or mopped over the surface and allowed to dry, which it does very quickly. The well-known brilliant pink or magenta-colored fluid turns very soon to a moderately dark brown, staining the skin for some little time, and is finally cast off by exfoliation of the tissues with which it has oxidized. It is most useful in subacute erythematous, papulo-squamous, and moist or weeping conditions. Immediate relief from the itching is usually experienced. It may be used 2 or 3 times daily. It is an oxidizing agent, and often serves to reduce thickening of the skin. To further protect the skin or to soften or lubricate the epidermis after the application, a zinc-oxid lotion or an indifferent ointment may in some cases be employed advantageously after the lotion.

A Nonirritating Ointment.—W. Allan Jamieson,[2] after alluding to the difficulty of finding a perfectly bland ointment for the treatment of diseases of the eyelids, states he has found one of Unna's cold-cream ointments, a little modified in proportions, to be an ideal ophthalmic salve. It is compounded as follows: Lanolin (Liebreich), ʒiij; ol. amygdalæ, aq. dest., āā. ʒss.—M. To this may be added with advantage 2 gr. of boric acid if the salve is intended to be kept for a long period. Patients express themselves pleased with the grateful sense of coolness, without smarting or irritation, which it imparts. [The formula is a good one, and the ointment is suitable for use either alone or as a base for various active drugs.]

Europhen as a Topical Remedy.—Saalfeld[3] recommends this remedy highly as the best substitute for iodoform. It possesses no disagreeable odor, does not irritate inflamed skin, and when mixed with water it constantly gives off small quantities of iodin. It is useful in varicose ulcers with eczema; in both hard and soft chancres; in pustular affections and folliculitis; and in many other dermatoses. It possesses, moreover, the power of arresting hemorrhage, and hence is useful in scarifications and in other minor operations upon the skin. [Eichhoff also has spoken in praise of this drug, which is one of the cresol-iodids, stating that it was the next best remedy to iodoform.]

Some of the Rarer Arsenical Preparations.—Danlos[4] has employed metalloid arsenic, the sulphid, and cacodylic acid. The first was prescribed in doses of 15–30 cgm. daily, suspended in honey. In psoriasis the effects of both metalloid arsenic and the sulphid were favorable, the eruption disappearing in due time without any unpleasant action of the drugs. Caco-

[1] Med. Rec., Feb. 29, 1896.

[4] Ann. de Dermat. et de Syph., No. 6, 1896.

dylic acid was employed in daily doses of 25 cgm., was well tolerated, and produced the usual effects of arsenic. It is generally considered not to be toxic, and because of its solubility is easily absorbed.

Local Anesthesia in Dermatology.—Brocq[1] discusses the varied procedures employed in the numerous small operations of cutaneous surgery. Dubreuilh has reiterated his views on the advantages of cocain injected into the skin. Since the solution must infiltrate the tissues to be anesthetized in order to reach the nerve-terminations, the injection should be not subcutaneous, but intradermic, injected into the superficial denser layers of the derma, from which it is easily diffused into the lower and looser layers. He uses a 2 : 100 solution, and as a vehicle a mixture of equal parts of distilled water and cherry-laurel water, which keeps well. He never uses more than 4 cgm. of cocain, even in subjects previously anesthetized. After the needle has entered the skin several drops are injected, when the needle is pushed on parallel to the surface, say 5 or 10 mm., a little fluid being driven into the skin. When the injection is completed there is noted about the point of the needle a white area 10 or 15 mm. in diameter, which is due to compression of the vessels by the injected fluid, the zone corresponding exactly to the anesthetized area. In certain regions, as the tip of the nose, the nostrils, fingers, multiple punctures are required. When the skin is too thin for endermic injections subcutaneous punctures suffice.

Lucas-Championnière recommends as a harmless and certain local anesthetic, subcutaneous intradermic injection of guaiacol, which one of his pupils, Quidré, first employed. An oily solution containing 5 cgm. of guaiacol to the Pravaz syringe is used. Complete local anesthesia is obtained in from 5 to 10 minutes. The olive oil used as a vehicle must be pure or it may produce tiny scars at the edge of the puncture.

Inunctions with ointments and oils containing guaiacol or cocain produce only a hypothetic anesthesia, although after friction of the skin with pure guaiacol a certain degree of insensibility is obtained at the end of 10 or 15 minutes, which favors electrolytic operations. Some individuals are especially susceptible and bear such applications badly.

Brocq states for all electrolysis operations he now employs a mixture of chlormethyl and chlorid of ethyl, directed in a fine jet on the part to be operated on.

SYPHILIS.

Infantile Syphilis.—The series of the Hunterian lectures on infantile syphilis by Coutts[2] contains much of interest. The subject-matter may be presented in a condensed form, as follows: The influence of the father in infantile syphilis was illustrated by the lecturer's notes of 100 families in which the mother presented no signs of syphilis, and the disease in the

[1] Jour. of Cut. and Gen.-urin. Dis., Mar., 1896, p. 109.

[2] Brit. Med. Jour., Apr. 25, 1896.

infant was presumably derived from the father alone, and a similar number in which the mother was unmistakably syphilitic. In the first set of cases, in which the mother was apparently free from syphilis, there had been 563 pregnancies, resulting in 187 abortions, 193 children who died early, and 183 children still living. This gives the high mortality of 56.6%, but poverty and other factors are probably as much responsible for it as syphilis in such a district as the East End of London. But the mortality amongst affected infants does not gauge adequately the evils of syphilis in the offspring, for the death of the fetus *in utero* and the harm wrought by it in infants who survive must also be reckoned. As an instance of the long persistence of the father's influence the writer cites a case in which the fourteenth pregnancy, 16 years after the occurrence of syphilis, resulted in a tainted infant. Concerning the influence of the mother, Coutts believes that Fournier's estimate of the "index of harmfulness" where the mother was alone infected, which he had placed at 84%, is probably too high. From the lecturer's notes of 100 families where the mother was syphilitic, and in the vast majority the father also, the statistics give a mortality of 58%—a result not differing much from that obtaining when the father alone was affected.

The greater severity upon the fetus of a maternal syphilis over a paternal one is due probably to (the reason unusually assigned for it) the deleterious influence of the vitiated maternal fluids upon the fetus in utero, and the slight increase in the mixed parental type over the maternal one is possibly owing to a greater certainty and frequency of transmissions.

Considering next the symptoms of inherited syphilis, the writer dwells especially on the power of the disease to produce a condition of atrophy which might be the earlier symptom or might appear as late as the third or fourth month. In these infants there might be no other evidence of syphilis, either because no other symptoms had been produced or because the snuffles and rash had been too slight to attract attention. In such case there was atrophy of the secretive and absorptive surface of the intestinal tract and fatty liver, so that food was not assimilated. It was probably for this reason that mercury was of little use in syphilitic and infantile marasmus. In acquired syphilis in infants the chief peculiarities of the symptoms were the scantiness and evanescent nature of the eruption, which might be easily missed, and the subsequent early and luxuriant growth of condylomata. That inherited syphilis was occasionally contagious the writer believed, but he would equally contend that the virulence of such contagion had been grossly and vastly overestimated. Concerning infection in inherited syphilis, he would follow in the same path as Henoch, the only limitations he would place on suckling by mother or wet-nurse being the presence of excoriations on her nipples and ulcerations or fissures about the mouth of the infected infant.

Is Inherited Syphilis Contagious?—Parker's[1] 20 years' experience at a children's hospital in a populous district of London has afforded him a large experience with infantile syphilis, resulting in skepticism concerning so-

[1] Edinb. Med. Jour., June, 1896.

called "inherited syphilis." He observes that few things are more certain than that a large number of infants the offspring of syphilitic parents sooner or later manifest symptoms of a disease which is called "inherited syphilis." Few things are more curious than that lesions supposed to be typically syphilitic are found in children neither of whose parents show any traces of syphilis, and from whom, after careful inquiry, a history justifying syphilis cannot be obtained. On the other hand, a certain number of children one or both of whose parents are obviously syphilitic never at any time of their lives show the slightest sign of an inherited taint. These circumstances lead the writer to ask, Is not inherited syphilis largely a misnomer? Is all disease inherited by an infant from syphilitic parents really syphilis?—*i. e.* Is this disease specifically contagious? Does it breed true? After considering the views of many authorities, including the teaching of Colles, the writer puts forth his views, summarized as follows: 1. The children of syphilitic parents very frequently show manifestations of a disease which is almost universally called "inherited syphilis;" 2. In a large proportion of cases this "inherited disease" is not syphilis at all, in that the disease is noncontagious, and would be better named "inherited from syphilis;" 3. This inherited disease is true syphilis only if it conforms to the ordinary tests which pertain to contact syphilis, and proves to be contagious; 4. The children of syphilitic parents occasionally inherit syphilis; 5. The mother suckling a child with such a disease may be infected by it; 6. A healthy wet-nurse and other persons brought into contact with such a child are even more liable to be infected by it than the mother; 7. Lymph taken from such a child, even though apparently well at the time, would probably or possibly invaccinate syphilis; 8. In reply to the question, Can a healthy woman give birth to a syphilitic child? the answer must be *no;* 9. Many women give birth to children who suffer from what is called "inherited syphilis" without themselves appearing to be infected. The explanation is obvious: this "inherited syphilis" is not true syphilis in the true sense, and the mother's so-called "escape" depends upon this fact; 10. There is no recent clinical evidence which fully realizes Colles' teaching—namely, a mother suckling her own syphilitic infant and escaping an infection to which a healthy wet-nurse suckling the same infant and other members of her family, who have merely handled this infant, have succumbed, the latter facts being essential if only to establish the contagiousness of the infant's disease in any and every given case asserted to be "inherited syphilis."

Pathognomonic Clinical Symptoms of Congenital Syphilis.—Silex[1] has investigated this subject (especially from the standpoint of the ophthalmologist), and concludes that there are three symptoms which may be regarded as pathognomonic: 1. Choroiditis areolaris, as demonstrated by him; 2. Certain notched defects of the inner upper incisor teeth (which he purposely avoids designating "Hutchinson's teeth," for the reason that authors have described various conditions under this name); 3. The existence of peculiar linear or streaked scars, or more properly pseudoscars, occupying the face,

[1] Berl. klin. Woch., Feb. 24, 1896.

particularly the region of the mouth and the lips (as shown in a photograph). [The pseudoscars referred to occupy mainly the lower half of the face; are linear and varied in size; radiate from the mouth, extending over the upper lip, chin, and cheeks; and give a shrivelled, as in aged persons, drawn, somewhat contracted, sclerodermic appearance to the face. The origin or mode of formation of these peculiar atrophic lesions has not been satisfactorily explained, for they are not true scars, as the microscope has demonstrated, and hence the name pseudoscar is more appropriate. It is possible, as Silex suggests, that they are produced by a drawing-in of the skin by reason of permanent muscle-contraction or atrophy, similar to that in aged persons.]

Notes on Syphilis; Syphiloma of the Nose of Unusual Form and Evolution; the Diagnostic Value of Syphilitic Cicatrices; Extragenital Chancres and their Prognosis; Professional Syphilis.—Morrow[1] makes some interesting and valuable remarks upon the forms of syphilis indicated in the above title. A case of syphiloma of the nose and body is given (with photograph), in which large tumors sprang from the skin like mushrooms, and were strikingly suggestive of the tumors of granuloma fungoides, the growths being of doughy consistence, but not suppurative. The most interesting feature of this case, however, was the large tumor-like infiltration which occupied the upper lip, blocking the aperture of the left nostril, and mounting upward on the left ala to the bony and cartilaginous junction. So peculiar was this lesion in its form and consistence, and so refractory to specific treatment, that a suspicion of its representing a combination of syphilis and tuberculosis was entertained by several skilled observers who had examined the case.

Concerning the diagnostic value of **syphilitic cicatrices,** it may be said that syphilitic scars taken singly may be exactly imitated by the scar following a burn, a traumatism, or the ulcerous process of some other disease. But when they are multiple they exhibit certain specific peculiarities in their circular or serpiginous outline, their grouping, their pigmentation, their localization; they may be just as characteristic of syphilis as were the lesions in their full stage of activity. The cicatrices of varicose ulcers of the leg may imitate closely those of syphilis in this locality, but they are generally limited to the lower third of the leg, while those of syphilis most often occupy the middle and upper third. [An excellent photographic illustration of typical multiple scars of the lower extremities is given, such as would be of great value in the diagnosis of any obscure nervous or visceral complication in the future.]

During the past 3 years 20 cases of **extragenital chancres** were observed in the writer's public practice. In private practice 10 physicians sought advice for chancres of the hand or fingers contracted in the exercise of their professional work. Of the 20 cases seen in public practice, 3 were upon the upper lip, 5 on the lower, 3 on the chin, and the rest in various localities. One of the lesions on the chin was distinguished by its enormous dimensions, occupying nearly the entire surface of the chin. The surface was ulcerated,

[1] Jour. Cut. and Gen.-urin. Dis., Apr., 1896.

the edges elevated, hard, and everted, presenting the appearance of an ulcerated epithelioma. That diagnosis had been made by the patient's physician, and he had been sent to the New York Hospital to have the "cancer cut out." In another case the lesion over the knuckle of the right hand resulted from a blow which the patient administered to a drunken tramp. The skin was broken by the force of the blow, and a few weeks later the lesion appeared, followed by a characteristic eruption. In the 10 cases of professional syphilis the chancre occupied the terminal phalanx of the index finger in 5 instances. In none of the 8 cases of digital chancre was the lesion hypertrophic or fungating. In 1 case only was there an exception in the form of absence of epitrochlear and axillary adenopathy, not the slightest trace of glandular enlargement at any period being detected. Two of the cases were infected at the same time in performing a perineal section in a syphilitic patient: the operator, through a hang-nail on the little finger; his assistant, by an accidental prick on the wrist by the knife used in making the section.

The prognostic significance of extragenital chancres is considered. Chancres of the fingers, especially, are thought to portend a bad type of the disease. This conception, that the gravity of a constitutional infection may be modified by the seat of inoculation, receives support, it is thought, from analogy of other infectious diseases. Thus, for example, there has been observed a marked difference in the relative mortality of mad-dog bites according to the region in which the virus is implanted. The mortality of rabies is four times greater from wounds of the face and neck than from wounds of the lower extremities. Chancres on the fingers, especially of those of the panaris type, are proverbially painful and are apt to be attended with severe glandular complications. Mauriac thinks that the bad reputation which chancres of the fingers possess is merited, and states that authorities are generally united on this point.

Professional Syphilis.—Medical men cannot be too strongly impressed with a recognition of the risks incurred, for professional syphilis is much more common than is generally supposed. The disease once acquired, the risk to others is great. A digital chancre involves serious danger to those with whom its bearer comes into professional relation. These facts suggest an ethical question of great practical importance—namely, whether a physician is justified in continuing his professional work while he bears on his hands such an active source of contagion. So far as the obstetrician is concerned, there can be no doubt as to his manifest obligation to abandon his work until the chancre is healed. One physician's case is cited who attended to a large obstetrical practice for several weeks after the existence of the chancre. It is just to say, however, that he had no suspicion of the syphilitic nature of the sore until the eruption appeared. The importance of an early diagnosis of the digital chancre cannot be overestimated. Almost all patients maintain that it must be a simple sore, a felon, a septic infection, or something else, and they cherish this delusion until their perceptions are quickened by the appearance of unmistakable constitutional symptoms. One of the writer's patients,

acting on the advice of his confrères, and believing that his chancre was an infected wound, had it scraped and cauterized, and the entire chain of glands, including the axillary, extirpated. The procedure delayed somewhat, but did not prevent, the evolution of the disease. [The notes of the cases presented, the information and sound teaching conveyed to the reader in this valuable article, are so instructive that a résumé has been given.]

Syphilis and Lardaceous Disease.—Weber[1] in his article on this subject endeavors to show how lardaceous formation in the tissues, when occurring in association with active tertiary syphilitic manifestations, and especially the lardaceous formation occurring in the immediate neighborhood of gummata, may be taken as additional evidence of the already probable view that active tertiary syphilitic manifestations are caused by the presence of a specific microbe at the site of the lesion. The conclusions which appear most probable may, he believes, be summed up thus: 1. There is a specific microbe of syphilis the local presence of which is the cause of the tertiary lesions of syphilis; 2. The metabolic products of this microbe have, like those of some other microbes, such as the staphylococcus pyogenes aureus and the bacillus pyocyaneus, the peculiar property of producing lardaceous formation in the tissues of the host.

Antagonism between Tuberculosis and Syphilis.—Abrahams[2] reports the notes of a case occurring in a Pole of 35, in which there existed positive clinical and pathological symptoms of tuberculosis pulmonalis, including the presence of tubercle-bacilli in the sputa in abundance. Under the use of creasote, ultimately in dram-doses thrice daily, the several symptoms improved considerably, and the patient disappeared from observation for 10 weeks, when he again sought treatment, on this occasion not for the tuberculosis, but for acute syphilis in the form of a chancre and the usual systemic symptoms of syphilis in the early period. Eight weeks later he was seen again; he had lost strength and was rapidly losing ground; had a cough and elevated temperature and pulse. Under cod-liver oil, the use of 50 mercurial inunctions, and the occasional use of sodium iodid not only did all the syphilitic symptoms vanish, but what was very remarkable was that positively all symptoms of tuberculosis, one by one, disappeared. Treatment for syphilis with iodid was occasionally resorted to. He has since enjoyed health.

Toxin-theory of Syphilis.—In an earlier paper, published in the Lancet in 1892, on the Pathology of Syphilis, Ward[3] advanced a working hypothesis deduced from a consideration of the phenomena of the hereditary disease, which he has recently applied to the question of latency of syphilis.[4] In order to cover the vast array of facts involved, it is evident that such an hypothesis must be of elemental simplicity; reduced to its lowest terms, it may be stated thus: 1. Syphilis is associated with the growth of a microbe in the organism; 2. This microbe produces a toxin which is the active cause of the phenomena of syphilis. In the light of modern bacteriology this theory seems

[1] Am. Jour. Med. Sci., Nov., 1895.
[2] Med. Rec., Dec. 28, 1895.
[3] Lancet, May 16, 1896.
[4] Lancet, 1896.

almost self-evident; however, until the specific microbe has been discovered, cultivated, and inoculated, and the toxin isolated, it must remain an hypothesis. The writer endeavors to show, however, that it is one that will work. The toxin must be supposed to share the properties of other microbial toxins; thus, it is diffusible and follows the laws of osmosis; it is irritating to the tissues and causes local inflammatory reaction; it is strongly chemotaxic and attracts leukocytes into the area in which it is present, and when existing in quantity in the circulation it causes symptoms of general toxemia. [The hypothesis is interesting and is approached by the writer from a scientific aspect; it is substantiated by many observations which he brings forward, and must be regarded as a valuable contribution to a theory about which we are likely to hear more in the near future.]

Experiments in Serotherapy for Syphilis.—Baget's[1] article on this subject goes to show that Tommasoli of Palermo was the first to experiment in syphilis with serum, and that he was induced to do so on the ground that, inasmuch as all attempts to inoculate lower animals with syphilitic virus had failed, it was allowable to suppose that in the blood of these animals there exists a chemic substance which renders them refractory, either preventing inoculation or rendering the reproduction of the virus impossible, and by inoculating man with the serum drawn from the blood of these animals a special resistance to the syphilitic virus is obtained. Pellizari took another and different view of the subject—in brief, that the products secreted by the syphilitic microbe have an antagonistic action upon the microbe itself, and hence that the introduction into the organism of the syphilitic subject of serum taken from another syphilitic, or "syphilitoxin," might prove beneficial or curative. In Tommasoli's experiments serum was taken from the lamb, dog, or rabbit, injected under the skin of the buttocks in doses of from 2 to 8 c.c. at certain intervals, and with gratifying results. Other investigators report negative results. Pellizari used the serum in doses of from 0.5 to 1 c.c. every third day or daily. Improvement followed these experiments. Mazza modified Pellizari's method, and employed serum taken from an animal that had been inoculated with the blood of a syphilitic subject.

Gilbert and Fournier[2] summarize the work done in this direction by Feulard, Tommasoli, Mazza, Kollman, Fournier, and Pellizari, and conclude that, while some cases showed marked improvement under the serum-therapy, others were uninfluenced by it.

Viervioroysky[3] reports 5 cases of secondary syphilis treated with subcutaneous injections of blood-serum derived from the blood of robust individuals affected with tertiary syphilis, the serum being filtered through a Chamberland filter and 0.5% of phenol added to it. From 4 to 20 c.c. (1 to 5 f℥), usually 10 c.c. (2½ f℥), were employed for each injection, the total number for each patient being about 20. The injections were made below the angle of the scapula. The patient rapidly improved; relapses occurred, but yielded

[1] Jour. des Mal. cut. et syph., 1895, vii. p. 155. [2] Brit. Med. Jour., June 1, 1895.
[3] La Sem. méd., 1895, xv. p. 186.

rapidly to renewed injections, the mucous lesions being the slowest to disappear.

Héricourt and Richet[1] also report favorable results in a case of tertiary syphilis with ulcerating gummata of the leg, in which general and local mercurial treatment had been used without benefit for 3½ months. The serum employed was taken from an ass into whom had been injected 20 cm. of blood taken from a subject in the secondary stage of syphilis, the blood-injection antedating the serum-injection 54 days. Cure was established in 4 weeks.

A. S. Barling[2] gives a case of phagedenic chancre with marked erythematous syphilis of the skin, the ulceration being so rapid and deep as to threaten loss of the penis, in spite of the internal use of mercury and the most approved and heroic local treatment; 10 c.cm. of an "antisyphilitic serum" were injected into the flank during a period of 4 days (instead of 7, as usual), the urgency of the symptoms seeming to warrant this course. The treatment had "a very good effect." There was distinct redness and increased swelling around the chancre on the second day.

Treatment of Syphilis by Injections of Syphilitic Antitoxin.—Edward Cotterell[3] has employed the serum of an individual who has passed through an attack of syphilis, and who has thus been rendered immune to subsequent attacks of this disease; 18 cases were treated by this method with the following results: 1. In the early stages of syphilis, when there is only a sore and glandular enlargement, injections of this serum cause the sore to heal rapidly, but the adenitis in the groin generally becomes intensely marked. The skin- and throat-symptoms are only slightly marked or absent; 2. When the case is not treated until the cutaneous and mucous symptoms have developed the eruption fades rapidly, more so, as a rule, than under mercurial treatment, but the throat-symptoms disappear rather slowly; 3. The general health improves; 4. The serum from an individual with well-defined secondary syphilis appears to be more acute than that obtained from a subject in the tertiary period. The dose of the serum injected was from ½ to 5 c.cm. [Further experiments are required to establish the value of this mode of treatment. As has been shown, some cases have been favorably influenced by the treatment, while in others the results have not been striking or have been negative. The source of the serum and antitoxin, especially the latter, are important points to be kept in mind in estimating the results. The abstractor believes that we shall soon hear much more of this theory in syphilis.]

A Case of Ulcerating Syphilis Cured by Feeding with Thyroid Gland.—Gouladse[4] records the good effects of feeding with fresh thyroid gland with salt, butter, and bread in severe ulcerative syphilis in a woman aged 25. From the fifth day on marked improvement was noted; the patient gained in weight, and the ulcer was soon completely cicatricized. The dose of 300 grains a day was gradually increased, 30 grains at a time, until 200

[1] Bull. méd., 1895, ix. p. 342.
[2] Brit. Med. Jour., Feb. 8, 1896.
[3] Med. Press and Circ., Aug. 28, 1895.
[4] Méd. mod., Oct. 5, 1895.

grains were taken 4 times a day. Every third day the treatment was intermitted for 24 hours. At the end of 5 months the patient was considered to be cured.

The Therapeutic Value of Erysipelas in Syphilis.—Rudolph[1] records 2 cases in which accidental erysipelas exerted a remarkably favorable influence over the course of syphilis. The syphilitic symptoms in both cases disappeared much more rapidly than would have been possible under the most judicious and active local and internal treatment. In 1 case the syphilis was of 19 years' duration, and there existed two syphilitic ulcers; in the other the date of infection was 4 years before cerebral symptoms, a severe cachexia, glandular enlargement, and joint-disease were present. [Experience has shown that while attacks of erysipelas usually exert a benign influence upon the existing symptoms of syphilis, often causing them to disappear rapidly, the introduction into the system of the erysipelas-virus cannot be regarded as permanently curative, inasmuch as relapses sooner or later generally occur.]

Treatment of Syphilis by Hypodermic Injections of Mercury.—Martin and Kiersted[2] report 9 cases treated by this method, from which they conclude that the disease treated by either soluble or insoluble preparations of mercury is not more efficient than other and commoner modes of administering the drug, and that it gives rise to so much pain that it is impracticable. The latter may be slight and transitory or almost unbearable, and may incapacitate the subject for work for days at a time. There is no certain way of preventing it, and it may suddenly manifest itself in those who have taken many previous hypodermic injections without complaining of it. Abscesses may certainly be avoided by the simplest antiseptic precautions. Before beginning the injections it should be ascertained that the kidneys are not diseased, since practically all fatal cases of salivation (and there have been many in this treatment) have occurred in subjects with diseases of the kidneys. When insoluble preparations are employed the site of injection should be particularly selected, so that in case of symptoms of salivation an incision may immediately be made through the seat of such injection and any unabsorbed mercury removed. When an immediate mercuric impression is desired hypodermic medication should be selected, supplemented by inunctions.

The Local Changes produced by Intramuscular Injections of Insoluble Mercurials.—Wolters[3] made an autopsy upon a woman who died of tuberculosis of the lungs. She was syphilitic, and during life had received 62 intramuscular injections of salicylate of mercury. She died 2 years after the last injection had been made, at which date hard lumps in the glutei muscles which followed the injections still remained. The gluteus maximus showed a number of spindle-shaped injections above the muscular tissue, and was joined to the gluteus medius by these projections. Under the microscope the muscular fibers were noted to be diminished and the septa of connective tissue enlarged, so much so that in the center of the growth the

[1] Centralbl. f. innere Med., No. 5, 1896. [2] Phila. Polyclinic, Jan. 4, 1896.
[3] Arch. f. Dermat. u. Syph., Bd. xxxii. H. 1 u. 2.

muscular fibers were surrounded by connective tissue. Neither mercury nor bacteria were found, but "mastzellen" were noted scattered around the fibers. The muscle was atrophied and showed fatty degeneration. The author concludes that the mercury acted as a positive irritant upon the connective tissue, giving rise to proliferation, especially in the muscular septa, and to the new formation of vessels, and the transformation of the muscles into soft masses.

On the Action and the Application of Intravenous Sublimate Injections as Recommended by Bacelli.—M. Dinkler,[1] assistant to Prof. Erb, concludes from his experience that the treatment of syphilis by the intravenous injections of sublimate, rational as it seems, cannot be recommended to take the place of established methods, such as inunction and the subcutaneous injections of mercurials. The method is not without technical difficulties, and on account of deficient development of the veins of the skin in very many patients is at once excluded. Thrombi also frequently are formed. On the other hand, on account of the quick action, the method is to be recommended in the rapidly-spreading forms of cutaneous and mucous syphilis, as well as in all difficult cases of syphilis of the central nervous system. [The author, while admitting that this method possesses certain advantages for some cases, does not endorse it; on the contrary, one concludes, after reading the article, that the obstacles to its successful practice are such that it cannot be recommended for ordinary cases. References are made to the experiments of Blaschko, Neumann, Lang, and Kaposi in the same field.]

The Iodids, other than Potassium Iodid, in Syphilis.—Briquet[2] discusses the literature of this subject, and cites several personal observations, his conclusions being that—1. All the iodids have clearly antisyphilitic properties; 2. The potassium iodid is, in a general way, the most active, but rubidium iodid, often better tolerated, appears to the writer to be almost its equal; 3. When potassium iodid is not tolerated one should not hesitate to have recourse to the sodium iodid, which succeeds very often; 4. Strontium iodid possesses no advantage, and it is well to avoid it against syphilitic cephalalgias; 5. Ammonium iodid should be reserved for certain cases of grave syphilis in which the potassium salt fails or appears to be inactive; it seems to be especially useful against tertiary eruptions; 6. Lithium and calcium iodids are slower and less positively active than the preceding iodids; 7. To obtain an effect about equal, or at least comparable, to that which the potassium iodid gives, it is necessary to prescribe the other iodids in like doses.

CHANCROID AND CHANCRE.

The Germ of Chancroid.—Lydston[3] takes up the question of the specificity of chancroid from the period of Bassereau, who demonstrated the duality of chancre and chancroid. Many researches have shown that the poisonous properties of chancroidal secretion are similar to those of other septic fluids. Pasteur, Koch, Lestikow, Morrison, and Mannio have all made

[1] Berl. klin. Woch., May 13 and 20, 1895. [2] Jour. des Mal. cut. et syph., Fév., 1896.
[3] Internat. Med. Mag., Dec., 1895.

this observation, and thus have confirmed a view which is supported by clinical experience. The first accurate work on the germ of chancroid was done by Ducrey of Naples in 1889. He described what he considered to be the pathogenic bacillus of chancroid, and showed that it was always associated with divers other microbes, and finally presented evidence which tended to show the specificity of the germ which he had discovered. Wehling and Krefting 3 years afterward confirmed his observations, but Jullien obtained only negative results. In 1892, Unna claimed to have discovered in sections of the tissues in the neighborhood of a chancroid a bacillus which he believed to be different from that described by Ducrey, but Nicolle, Columbini, and others afterward showed the identity of the two. Columbini's researches in particular go to show that a special form of bacillus is to be found in chancroid and its attendant bubo, and that it is neither susceptible of cultivation nor of inoculation on the lower animals. As Lydston observes, the latter point militates somewhat against the specificity of the germ. In a comprehensive article Le Damany describes the Ducrey bacillus, as found in the pus of simple chancres, as follows: The bacillus, when viewed singly, is short, ordinarily thick, with rounded extremities, having in the center a clear space. It is frequently grouped in masses or short chains, the latter being sometimes fasciculated. It is not uniformly disseminated throughout chancroidal pus, some preparations, according to Le Damany, containing a very large number of germs, while in others very few can be detected. They are found both within and without the pus-corpuscles. Lydston is of opinion that, however strongly the claims of the Ducrey bacillus may be presented, a survey of the varied and manifold kinds of germs found in chancroidal pus in intimate association with the alleged specific bacillus bears abundant testimony to the decidedly mixed character of the infection. The most important evidence of the specificity of the Ducrey pathogenic organism is the fact that numerous and competent observers have failed repeatedly to find the germ in anything but chancroid. The chain of evidence will be incomplete until pure cultures can be made outside of the tissues. The author of the paper is not yet prepared to accept the specificity of the Ducrey bacillus as absolutely proven, though he has faith in the results thus far recorded. He agrees with the view of Ducrey, that chancroid, as it presents itself clinically, is a decidedly mixed infection, and hence is surrounded with difficulties in its pathology.

Pseudochancre.—Gottheil[1] calls attention to the rarity of syphilitic reinfection. Literature gives many recorded cases, but a careful analysis shows that the vast majority of them are open to grave doubt. In many cases of reported reinfection sclerosis is the only symptom that is noted, the other manifestations of a secondary nature being either mild or ill defined. Sigmund long ago pointed out that there occurred tertiary ulcerations that possessed all the characteristics of the true sclerosis, and Fournier has classified several lesions which simulate the initial chancre. Bregeal called attention to gumma of the penis, the frequency of its occurrence rendering it

[1] N. Y. Med. Jour., Sept. 28, 1895.

extremely liable to be mistaken for a primary lesion. Von Düring has observed pseudochancres in which an apparently characteristic induration lasted for from 5 to 6 weeks, and which were never followed by secondary symptoms. Keyes believes that in most of the recorded cases of a second attack of syphilis a pseudochancre was mistaken for a true sclerosis, and Taylor has expressed a similar opinion.

Nevertheless, there are a few undoubted cases on record. According to the author of this paper, a true chancre may be simulated by—1. An artificial induration, such as may be produced under an herpetic or chancroidal ulceration by the use of nitrate of silver, carbolic, nitric, or acetic acid and the like; 2. A nodular lymphangitis in gonorrhea; 3. Scabies; 4. A secondary induration occurring late in the disease at the site of the initial lesion, constituting the pseudochancre of Fournier; 5. A syphilitic papule or tubercle; 6. An ulcerating gumma; 7. An epithelioma. Several interesting cases are recorded that had been erroneously regarded as primary chancre by competent observers.

Syphilitic Chancres of the Urethra.—Baum[1] reports 4 cases of urethral chancre, the diagnosis having been established by other later symptoms of syphilis. The chief point of interest in the cases is that in all of them the disease had been regarded by other physicians as gonorrhea. The author is of opinion that one should not make a diagnosis of gonorrhea in cases of urethral discharge without an examination, for gonorrheal infection and chancre of the urethra may be coincident, or the latter may occur without gonorrhea.

Phenol in the Local Treatment of Chancroid.—Neisser[2] advocates the cauterization of soft sores with phenol, for the reason that it possesses the advantage of not provoking inflammatory induration, as does silver nitrate, and consequently does not obscure the diagnosis. As a rule, one application suffices, and no further treatment than that commonly employed for a simple ulcer is required.

MATERIA MEDICA EXPERIMENTAL THERAPEUTICS AND PHARMACOLOGY.

By HENRY A. GRIFFIN, M. D., and COLMAN W. CUTLER, M. D.
of New York.

The progress of the past year has been most marked in two directions—the development of the therapeutic uses of the animal extracts and the production of synthetic compounds. In the case of the animal extracts Oliver and Shafer's experimental work has borne practical results in the treatment of Addison's disease and asthenic conditions of the vasomotor system by the medulla of the suprarenal capsules. This opens a large field of possible usefulness, and seems to establish the claims of organotherapy on a firm basis. Baumann appears to have isolated the active principle of the thyroid gland, which is a very important step toward scientific precision, and foreshadows the same achievement in the case of the suprarenal bodies and possibly the bone-marrow. Wood hints at an association between the spleen and the thyroid, and seems to believe that a splenic extract may be of use in exophthalmic goiter. It is unwise to be sanguine, however, over the indiscriminate uses of glandular extracts. What success has been attained is the legitimate and logical sequence of experiment and scientific induction, and empiricism will endanger, or at least delay, the best results. Our knowledge of nucleins has increased, but only from a physiologic point of view; their therapeutic uses are still unknown. Chittenden's paper summarizes the present status from the side of physiologic chemistry. It is possible that further research in this direction may throw important light on the mystery of uric acid.

With regard to the synthetic drugs which are constantly evolved from the German laboratories and manufactories of chemicals, it must be said that the physician is in danger of accepting the assurance of the chemist with too great confidence. A more thorough knowledge of organic chemistry would enable us to judge more clearly, or at least to see what a narrow line separates the harmless from the dangerous compounds. Numerous instances of poisoning by some of the most familiar of these drugs have been noted this year, and it will certainly not be amiss to caution the profession against their indiscriminate use. Too little is known of their mode of action on the human organism, and, it may be added, too little is known of the latent possibilities of the individual to justify any but a cautious and watchful use of these new remedies. The synthetic remedies are, for the most part, hypnotics, antipyret-

ics, or antiseptics, and if used to excess are either depressant or directly harmful to the heart or blood. An exception is guaiacol, as to which there has been but little reaction from the high favor in which it was held last year; its production synthetically will establish its purity and increase its usefulness.

It would seem that the oil of sesamum, a pure oil containing no free fatty acid, may be substituted for cod-liver oil; as it is readily absorbed, and in many cases much better tolerated, it should be more useful as a food.

It was to be expected that Bunge's views of the absorption of iron would be contested, and it is a relief to find that his hypothesis is not tenable.

All references to the advances made in serum-therapy have been avoided, as the subject will be treated in full in other departments of the *Year-Book.*

Acetanilid, Poisoning from the External Use of.—Newton[1] tells of a child with extensive burns of face, arm, and leg. The central portions of the wounds were sprinkled with acetanilid. Between 20 and 40 gr. were used on 5 occasions in 9 days. When this dressing was applied on 2 successive days there followed in 4 hours a condition approaching collapse, and marked by extreme cyanosis, weak and rapid pulse, and dilated pupils. Recovery was gradual, the cyanosis and cold extremities lasting several hours. The next morning the patient was as well as usual. As the symptoms were not attributed to the acetanilid, the dressings were continued, and the same condition was repeated. [This case is of interest because, as the author well says, in using the coal-tar products externally we are not free from the dangers which attend their internal exhibition. They are remedies whose powers, limitations, and dangers are not yet understood, and many statements regarding them have proved misleading in practice.]

Frollington and Pratt[2] assert that there is no danger of poisoning from absorption of acetanilid externally applied. [Such a statement is certainly not justifiable regarding agents of whose physiologic action we have so little knowledge as of the coal-tar products.] Two similar cases of poisoning are reported by Rook.[3] In one case, an infant of 4 days, the poisoning resulted fatally, the child becoming deeply cyanotic and dying in a few hours.

Carmalt[4] relates a similar experience which, however, did not result fatally.

Acetanilid, according to Munger,[5] may be used for insufflation on nasal wounds after operations. The pure powder proved a better dressing than when mixed with zinc stearate. The healing seemed more rapid, frontal headache and neuralgic pains following operations seemed less frequent, and no cyanosis, profuse sweating, cardiac depression, or unfavorable systemic effects were observed. Persistent hemorrhages were apt to follow the use of the drug upon septal wounds.

Alkaloidal Tinctures, Strength of.—In the report made at the annual meeting of the British Pharmaceutical Congress[6] it was shown that there was a very wide range in the alkaloidal value of the commercial samples of the

[1] N. Y. Med. Rec., Mar. 7, 1896.
[2] Am. Jour. Med., Sci., Aug., 1895.
[3] Jour. Am. Med. Assoc., 1896, xxvi. p. 239.
[4] Yale Med. Jour., 1896, p. 131.

[6] Therap. Gaz., Nov. 15, 1895.

tinctures of the British Pharmacopœia. Some of the tinctures were 2 or 3 times the strength of others, even in the case of such tinctures as those of opium and cinchona, which are directed to be made from standardized drugs, while in the case of the tincture of nux vomica one of the samples was found to be about $\frac{2}{3}$ as strong as it should be, and several others were deficient in alkaloid. The tinctures of conium were, as a rule, worthless. Attention was drawn to the fact that the relative proportions of alkaloid and extractive contained in different samples of the same drug varied between very wide limits. The investigation showed that poor results might be expected when only standardized crude drugs were used, and that reliance should be placed in doubtful cases only on an assay of the finished product. The writer, Mr. Christie, says every liquid representing a drug containing a powerful active principle should be subjected to careful assay, the strength being stated on the label, and a distinctive name applied to such preparations as a class which would indicate the nature or aim of the class of preparation, as, for instance, "normal liquids."

Amygdalate of Antipyrin.—This preparation is named tussolo in Italy, where it has been recommended in the treatment of whooping cough.[1] The dose for infants is said to be from $\frac{3}{4}$ to $1\frac{1}{2}$ gr. several times a day.

Anarcotin.—Roberts[2] discusses a neglected alkaloid of opium which came to his attention during his travels in India as a member of the Royal Commission on Opium. By far the most abundant alkaloids of opium are morphin and anarcotin, the latter representing the antimalarial properties of the drug. Numerous experiments and an experience dating back 56 years in India show that anarcotin is scarcely inferior, and in some classes of cases is superior, to quinin as an antiperiodic. It is recognized that certain cases of malarial fever which resist quinin yield to anarcotin, while in a certain percentage of cases it proves wholly ineffectual. The alkaloid was originally named narcotin by its discoverer, Derosne, but as it is, in a pure state, entirely devoid of narcotic qualities, it has been renamed, by Dr. Palmer, anarcotin. A summary of Dr. Palmer's experiments in 1857–59 is as follows: 546 cases of malarial fever were treated with anarcotin in doses ranging from 1 to 3 gr. Of these, 541 were cured and 5 died. In general, he says, in 70% the fever was arrested at the second paroxysm after the drug was administered; in 20% the arrest was equally sure, but not quite so quick; and in 10% the medicine did not appear to have any effect. The drug is stated to be perfectly insoluble and tasteless. Small doses produce no effect; 1 g. caused vomiting in 3 out of 4 dogs, 0.5 g. in 1 out of 2. When added to the food in doses of 0.3 to 0.5 g. it had no effect on temperature, respiration, or pulse. There was a slight increase in the water in the stools and in nitrogen unabsorbed. This led to a loss of weight, which was immediately regained on stopping the drug. Anarcotin chlorid (made by dissolving anarcotin in dilute HCl, drying, and redissolving the chlorid in chloroform; the addition of ether causes precipitation of crystals of anarcotin chlorid) is very soluble, with an intensely bitter taste; 1 g. in 3 dogs caused no vomiting, and with 0.3 to 0.5 g. sub-

[1] Univ. Med. Mag., Sept., 1895.

[2] Brit. Med. Jour., Aug. 17, 1895.

cutaneously there was no alteration in blood-pressure, pulse, respiration, or temperature.

The **anhalonium Lewinii** is a plant of the cactus order growing in the valley of the Rio Grande in Mexico. The dried tops constitute the mescal buttons which are used by the Kiowa Indians in their religious ceremonies. This plant has been studied by Lewin and Heffter, and more recently by Prentiss and Morgan,[1] who have added much to our knowledge of its nature. The mescal buttons are brown, circular, 1 to $1\frac{1}{2}$ in. in diameter and $\frac{1}{4}$ in. in thickness. They are brittle, swelling, however, in the mouth and becoming soft. The taste is very bitter and nauseous, with a persistent after-taste. A marked sensation of stinging or tingling is produced in the fauces. The powdered button is odorless when dry, but acquires a nauseous odor when moistened. An alkaloidal substance, syrupy in consistence and having an intensely alkaline reaction, was obtained by Lewin in 1888. This has been separated by Heffter into 3 alkaloids: the first forms brilliant, colorless, needle-shaped crystals; to this was given the name anhalonin, $C_{12}H_{15}NO_3$. The second formed non-lustrous, white rhombic tablets. The third was an amorphous and very poisonous alkaloid left behind in the mother liquid. Besides these there are at least two resinous bodies, as well as a wax-like substance. Investigations now being made will probably throw more light on the subject. The conclusions of the authors as to the physiologic action, drawn from 6 experiments, may be summarized as follows: The production of visions ranging from ill-defined flashes of color to most beautiful figures, forms, landscapes, the vividness of the colors being most striking. The conclusion is that this effect is due to a stimulation of the centers of vision in the brain. In one case there was a persistent ache and sense of exhaustion in the occipital region, lasting for several days after the drug had been taken. Dilatation of the pupils was marked in every case, and persisted for from 12 to 24 hours after the drug had been taken; there was also a slight loss of the power of accommodation. More or less muscular depression was present in every case, this being the first effect noticed: the authors are of the opinion that this is due to the central action, and not to a direct influence on the muscles. Partial anesthesia of the skin was present in 3 cases. The heart-action was a little slower and weaker at first, but soon regained the normal. There was inability to sleep for at least 12 hours after the effects of the drug began to pass off. A similar experiment made by Briggs[2] gave different results, the pulse rising suddenly to 160, and the respiration becoming so rapid that there was great distress; this was followed by unconsciousness; in 6 or 8 hours the condition again became normal. [It seems probable that the drug taken by Briggs was not identical with that at present under examination. The anhalonium Lewinii resembles cannabis indica in producing visions, but the latter is hypnotic. There seems to be little similarity between this and any known drug. In the tendency to produce wakefulness and the dilatation of the pupils the effects suggest the action

[1] Therap. Gaz., Sept. 16, 1895.

[2] Lewin, Arch. f. exper. Pathol. u. Pharm., Bd. xxxiv. H. 5 u. 6.

of cocain. The visions of cannabis indica are generally of a gay character, producing much merriment, accompanied by a great inclination to muscular movement.[1] The visions from anhalonium Lewinii, on the other hand, provoked wonder and admiration, but no merriment, and there was present a disinclination to make any muscular effort.]

In a later communication[2] the authors give certain indications for the therapeutic use of the drug. They say: The extreme effects mentioned—such as the production of visions, partial anesthesia of the skin, loss of sense of time—are the effects of an intoxicating dose. They would not appear under ordinary circumstances in the administration of the drug in proper therapeutic doses. Judging from the physiologic action, then, and from cases which have already been reported,[3] the authors conclude that the mescal buttons may be of use in the following conditions: general nervousness, nervous headache and cough, abdominal pain due to colic; as an antispasmodic in hysterical conditions; as a cerebral stimulant in melancholia and allied conditions; as a substitute for opium and chloral in some cases of mania and acute delirium and in insomnia caused by pain. The following preparations may be used: tincture anhalonii (10%), dose 1 to 2 teaspoonfuls; extractum anhalonii fluidum (100%), dose 10 to 15 drops; pulvis anhalonii, dose 7 to 15 gr.; anhalonin: Experiments are now in progress to determine the identity, physiologic action, and dose of this alkaloid.

Animal Extracts.—Prof. Wood[4] in a clear and scholarly manner summarizes our present knowledge of the physiologic action and therapeutic use of these substances. The use of thyroid extract in myxedema rests on a firm scientific foundation. It has been tried empirically in many diseases. "In hypertrophy of cicatricial tissue resembling keloid, possibly true keloid, thyroid extract has caused absorption of the hypertrophied and cicatricial tissue. It has been used with success in simple goiter; in the goiter of Switzerland, before calcareous degeneration has taken place, it will bring about destruction and absorption of the overgrown tissue. In excessive obesity with tendency to weakness and anemia, in which exercise and diet fail, thyroid extract should be tried. It is sometimes useful in melancholia, but how it acts we do not know. When thyroid extract is used freely in continuing doses, it sometimes produces a series of phenomena constituting so-called thyroidism. The most important of the symptoms are loss of weight, shortness of breath, and a weak and rapid pulse. In all cases in which the extract is being used freely and continuously, but especially in those cases in which the symptoms are not those of myxedema, the patient should be weighed at least every 2 weeks, and any undue loss of weight or disturbance of circulation or respiration should be the immediate signal for the withdrawal of the remedy or a great reduction of the dose. The thyroid extract has been largely used in exophthalmic goiter, but here, I am sure, it does harm. The cause of the symptoms in exophthalmic goiter is undoubtedly the excessive development of the thyroid secretion."

Thyreoiodin.—Baumann[1] claims to have isolated the active principle of the thyroid gland. It is an organic compound containing a large proportion of iodin and ½% of phosphorus. The author obtains thyreoiodin in the following manner: The thyroid gland is hashed and boiled for several days with a 10% solution of sulphuric acid, whereby a fine, flaky precipitate is formed, which is separated and repeatedly boiled with 85% alcohol. The residue obtained on evaporating the alcoholic liquor is dissolved in soda solution, the solution thus obtained filtered and treated with diluted sulphuric acid, when thyreoiodin separates as a brown, amorphous substance. Experiments conducted by Dr. Roos are said to show that this new body has the same effect on the human organism as the thyroid gland itself. Several substances have been obtained by different investigators from the thyroid gland; thyreoproteid, thyreoantitoxin, and thyreoidin have been supposed to embody the active principle, but they have not found favor. From another source[2] we learn of thyroiodin, which may be identical with the thyreoiodin already mentioned, although the description varies somewhat from that given above.

Thyroiodin is said to be a white powder of the same specific gravity as sugar of milk; 1 g. represents 1 g. of fresh gland and contains 0.3 mgm. of iodin. The dose for adults is 0.3 g. 1 to 3 times daily. Maximum dose 2½ g. daily. The method of its production and its source are not given.

According to Hutchinson,[3] the thyreoantitoxin of Fränkel and the body isolated by Drechsel are crystalline, proteid, free, and clinically inert. Hutchinson found that the proteids of the thyroid are practically 2 in number—a nucleoalbumin, which is inactive, and a colloid matter, which he believes to be the active principle of the thyroid. In this substance Hutchinson found a considerable quantity of iodin in organic combination, which seemed identical to that found by Baumann. Ewald[4] discusses Baumann's thyreoiodin, and states that its discovery is a very important step in therapeutic progress. By this means, says the author, the long-desired precision of dosage and the purity of the active substance are obtained. According to the investigations of Roos, Treupel, and Ewald,[5] thyreoiodin contains the specific constituents of the thyroid in toto, and may therefore be substituted for the fresh gland or for the extracts and dry preparations.

With regard to the action of the thyroid preparations, two components must be distinguished—one which includes the visible results, the second which produces certain subjective symptoms, which may be mere discomfort or outspoken disorder; these have been called thyreoidismus. Metabolism may be increased, and this may produce changes in the general condition, such as general weakness, anorexia, nausea, thirst, sleeplessness, vertigo, pains in the back, palpitation, and pseudoangina pectoris. These symptoms are more or less marked in all sudden changes of metabolism which are associated with a rapid solution of albuminous substances and an increased combustion of fat. No important

[4] Wien. med. Blatt., June 4, 1896. [5] Ibid.

influence on the pulse has been observed. There is no possibility of iodin-poisoning, the quantity being much too small. Ewald has frequently found sugar in the urine after treatment with thyroid preparations, and in 1 case this has persisted for 4 years, but with no other symptoms of diabetes. As a rule, the glycosuria is only temporary. The author gives a summary of our knowledge of the physiology of the thyroid gland and of the thoroughly rational process by which the natural secretion of the gland is replaced by the artificial product. If the treatment is pushed too far, the symptoms of thyreoidismus result. The daily quantity is, at the most, 10 tablets, corresponding to 3 mgm. of iodin. In myxedema and sporadic cretinism or infantile myxedema the value of the treatment is unquestioned. In psoriasis and other skin-diseases, such as lupus, ichthyosis, xeroderma, etc., its efficacy, according to Ewald and other observers, is not yet established. In corpulence, however, the reports are unanimous that the loss of weight is prompt, but not lasting. The action of the thyroid preparations being to cause a destruction of albuminous matter and combustion of fat, the ideal method is to supply the loss of albuminoids by a suitable diet, allowing the fat to diminish without injury to the organism. The corpulent may be divided into two classes—those who are fat because of an improper diet, and those who in spite of a strict regimen remain fat; these two classes are not to be distinguished in their reaction to the thyroid treatment. Both are at times refractory, and the cause of this is at present not known. Thyreoiodin is as efficient in these cases as the extracts and dried preparations of the gland.

In a case of pronounced and persistent exophthalmic goiter under Wood's care there was an injury to the spleen, followed by abscess, which was opened, and after months of severe illness recovery occurred. In the second or third week of the splenitis the goiter began distinctly to diminish. By the fifth week the goiter had disappeared, and since the patient has recovered from her illness the goiter has not returned. We know excision of the thyroid gland produces enlargement of the spleen, so that there is some relation between the two glands. Wood has used splenic extract in 3 cases of exophthalmic goiter; 1 went home "apparently cured, and the 2 others were much benefited." The author narrates a case in which Addison's disease was apparently cured by the use of the glycerin extract of the suprarenal capsule. Other cases have come to his notice in which benefit was derived, and still others in which there was failure. In some cases failure may be avoided by ordering the suprarenal capsules from a veterinary surgeon who has himself taken them from the beef. In the cases cited the glycerin extract was used in doses of 10 to 15 ♏ hypodermically.

In continuance of the investigations of Oliver and Shafer (noted in the *Year-Book* for 1896, p. 1098), which show that the product which the medulla of the suprarenal capsule furnishes to the blood has a special affinity for muscular tissue, both striped and plain, and is in all probability intimately associated with the production of muscular tonicity, 2 cases of Addison's disease are reported,[1] 1 of which was notably benefited by the treatment. Oliver thinks it

[1] Therap. Gaz., Mar. 16, 1896.

probable that the adrenals may be of use in all conditions in which the vascular tone is reduced. In anemia and asthenia the blood gravitates to the veins of the abdomen on assuming the upright position; by the use of an arteriometer the radial artery is seen to increase in diameter in the recumbent and diminish in the erect position—the opposite of what occurs in health. This abnormal condition is taken as a general indication for the use of the suprarenal treatment. The author has observed that, as a rule, in a few days' treatment the normal relation of radial caliber to posture is restored, and maintained as long as the treatment is continued. He has also observed a rapid increase in the percentage of hemoglobin during the suprarenal treatment. Oliver has treated 2 cases of cyclic albuminuria in this manner with great temporary benefit, the albumin, however, returning when the treatment was discontinued. As a hemostatic suprarenal capsules have not proved themselves efficient, because of the enormous increase of blood-pressure which they cause.

Extracts of the bone-marrow and of the spleen have been used, but without success, in the treatment of leukocythemia. Wood[1] thinks it probable that glycerin-extracts of marrow will not prove of value in these cases, since there is already too much marrow-activity. In severe anemias, however, there is sufficient evidence to warrant the administration of the medullary glycerid. Danforth[2] expresses the opinion that this treatment has shown better results than that with iron or arsenic. Janeway[3] lays stress upon the uncertainty and gravity of the prognosis in cases of pernicious anemia. He has seen a marked temporary improvement following treatment, but has yet to see a case in which the result was permanent. He related a case, however, in which a marked improvement was brought about, and persisted to the present time, from the use of bone-marrow. Stengel[4] has seen marked temporary improvement in a case of pernicious anemia from the administration of a glycerin "jam" of bone-marrow. The glycerin extract made from calves' ribs was inefficient; raw bone-marrow soon became repulsive to the patient; so the author took the red marrow from the tibia of the calf, mixed it with an equal quantity of glycerin, and rubbed it up in a mortar; in this way a preparation was made, the taste of which was pleasant, and which did not derange the stomach of the patient. From 1 to 2 oz. were administered daily.

Cohnstein[5] reports the results of the treatment of 22 cases of chlorosis by means of an extract of the spleen. In $\frac{2}{3}$ of the cases there was a distinct improvement. In a minority of the cases there was no perceptible result. The extract is said to have the consistency of honey, and to be sterile and permanent. It has an aromatic or spicy odor and taste, and may be used in the same manner as Liebig's extract. It is manufactured under the name of erythrol. Gritzmann[6] has treated 4 cases of malarial cachexia with the spleen and bone-marrow of cattle, with apparently favorable results.

Antispasmin.—Stoos[1] speaks favorably of the use of this remedy in whooping cough, especially in children under 1 year, in whom bromoform may be dangerously narcotic in its action. The action was not always the same; while in most of the cases the severity of the spasms was at once diminished and their frequency lessened, in some cases this action was reversed. The only other action of antispasmin, even in very young infants, was a slight constipation. For children under 1 year the dose is $\frac{1}{4}$ to $\frac{1}{6}$ gr. 3 or 4 times a day. [The composition and dosage of antispasmin are given in the *Year-Book* for 1896, p. 555.]

Apolysin.—Nencki and Javorski[2] write of a new analgesic and antipyretic which is closely allied to phenacetin. In the latter acetic acid is combined with phenetidin, whereas in apolysin citric acid is used. It is a fine yellowish-white crystalline powder, slightly acid to the taste and acid in chemic reaction. It has a slight odor, is soluble with difficulty in cold water, and is readily soluble in hot water. Lithium, magnesium, and sodium salts of apolysin have been made. The authors have used apolysin in a variety of cases, including croupous pneumonia, scarlet fever, typhoid fever, influenza, various forms of neuralgia, etc., in doses not larger than 92 gr. daily, single doses from 8 to 23 gr. The great advantage which this substance has over phenacetin is its solubility and consequent greater rapidity of action. No unpleasant effects were noted from its use. It should not be given on an empty stomach or when the secretion is very acid, as decomposition ensues. Jéz[3] reports that in his hands apolysin has not shown itself a useful analgesic, and that it is only weakly antipyretic in its action, but that in 50 cases no ill effects were noticed. Cerna,[4] however, has seen death follow the intravenous injection of 45 gr. in a dog. Death was caused by a simultaneous arrest of the respiration and heart, the symptoms of asphyxia being well marked. There was considerable hematuria and cyanosis, with a distinct discoloration of the blood.

Arecolin Hydrobromate.—Mouquet[5] concludes from experiments on 2 horses that this drug acts similarly to, but more powerfully than, eserin and pilocarpin; it is also cheaper than the latter. Bardet[6] claims that the drug approaches pelletierin more nearly than it does eserin and pilocarpin. Areca-nut has been used successfully as a teniacide. Because of its energetic action small doses, $\frac{1}{16}$ to $\frac{1}{32}$ gr., must be used at first. Lavogna[7] says that a 1% solution in the conjunctival sac is followed by some warmth, tears, and slight spasm of the lids. The signs of irritation pass quickly and are followed by a slight bulbar hyperemia. In 5 minutes myosis begins, which reaches its maximum in about 10 minutes and lasts about 30 minutes, when the pupils begin to dilate, the normal size being reached in about 70 minutes; $1\frac{1}{2}$ hours afterward slight mydriasis is seen. The spasm of the ciliary muscle reaches its

[6] Ibid.
[7] Therap. Monatsh., 1895, H. 7, S. 364.

maximum in from 1 to 6 minutes, reaching the normal again in about 35 minutes after the instillation.

Argentamin.—Munger[1] reports that this was of much value in the treatment of catarrhal and purulent rhinitis, a 5–10% solution being applied to the well-cleansed mucous membrane by the physician not oftener than every second day. A ½ to 2% solution may be given the patient for daily use at home. The older silver salt seems better in chronic laryngitis.

Argonin.—Liebrecht[2] claims for this new silver salt important properties, as it apparently possesses the bactericidal, but not the caustic, action of the nitrate. Casein acts as an acid and gives a soluble silver salt when a solution of its sodium compound is mixed with nitrate of silver. Alcohol gives a white precipitate in the form of a fine powder, argonin, which is easily soluble in hot water, with difficulty in cold water. This substance is believed by Meyer to have antiseptic properties of considerable value. Solutions of a strength of 3% and 4% have no caustic action on mucous membranes, and are apparently efficient in affections of the urethra and conjunctiva.

The Atropin Group.—After a review of the literature for the past 20 years, Sharp[3] concludes that daturin and duboisin may be called impure atropin. The varying effects obtained by different observers in the case of hyoscin and scopolamin may be accounted for on the supposition that neither is a definite base. Hyoscyamin may be considered identical with atropin. Atropin is the alkaloid of which we know most, and may be called the fundamental or representative base; and our knowledge permits us to say at least that in hyoscin and scopolamin we have a certain proportion of atropin along with a certain proportion of a conversion-product or decomposition-product of atropin which might be called *a* tropeine. The author has used hyoscin hydrobromate clinically, and is unable to find that it differs in any way from atropin. He thinks that different samples may vary and account for the different results obtained by different observers. In favor of there being only one base the following considerations are advanced: 1. All authorities agree that one base readily passes into the other, as, for example, atropin may be changed readily into hyoscyamin, and vice versa; 2. In experiments on the frog's heart one will replace the other; stop the heart with muscarin, and any one will start it; stop the heart by simple exposure to the air, and any one will start it, within certain limits; 3. They are all mydriatic; 4. They all possess hypnotic action; 5. They all react in the manner of caustic potash or soda toward alcoholic solution of mercuric chlorid. Instead, then, of multiplying names, we should call atropin what is usually atropin, and get the others free from any admixture, and name the resulting products by names corresponding to homatropin.

Belladonna-poisoning.—Montgomery[4] describes a case in which the diagnosis was rendered doubly difficult by the absence of dilatation of the pupils, and because the poisoning was caused by a belladonna plaster the pres-

[1] Am. Med.-Surg. Bull., May 16, 1896.

[4] Med. News, Jan. 25, 1896.

ence of which was unsuspected. [The absence of mydriasis would certainly suggest the presence of another ingredient in this plaster, so constant a symptom of belladonna-poisoning is dilatation of the pupils.]

Benzonaphtol has been mentioned favorably this year as an intestinal antiseptic. Huchard[1] has recommended its use in cachets with powdered charcoal and pancreatin. Clark[2] reports his success with it in an epidemic of dysentery in Cuba. The total number of cases treated was 137, of which 23 were grave and 114 mild. The mortality among those treated with ipecac, calomel, opium, and the other usual agents was 9%, with the benzonaphtol just over 2%. Recovery was more rapid and there was not the usual depression; 46 gr. a day were given to adults and about the same dose to children. [We are gratified to observe these favorable reports, for benzonaphtol has certainly not been given its deserved credit as an intestinal antiseptic.]

Borax-insufflations in Constipation.—Merkel[3] reviews the literature of intestinal disorders, especially of flatulence, and describes the results obtained by Crämer in constipation by the use of boric acid. The nozzle of a powder-blower, well oiled, is introduced into the rectum and 30 to 60 gr. are insufflated. The treatment should be continued for 4 to 6 weeks, but marked improvement may occur in the first week, often after the first injection. Generally, within 15 minutes there is a tendency toward a movement of the bowels. There is a large amount of fecal matter expelled with considerable odorless gas. The stool is soft in consistency. If intestinal atony is present, other methods must be used in combination to produce a thorough daily evacuation.

Boxwood has been recently recommended by Artaud and Gadot[4] as useful in certain forms of intermittent fever with hyperplastic and parenchymatous lesions, in which it acts as a cholagogue. The drug has been employed for a long time in syphilis, herpes, and rheumatism, but has, it would seem deservedly, fallen into disuse. As an antipyretic, however, it has been employed by Pavia and others, who consider it a useful substitute for quinin in malarial fevers. The tincture of buxus and buxin sulphate are said to have drastic properties.

Brazilian lantana is recommended by N. Lugo-Vina[5] of Cienfuegos as a powerful antiperiodic. It is said to be a verbenaceous plant growing in the South American forests. It has long been esteemed by the natives in the "marsh fevers." The active principle is lantanin, the daily dose of which is 15 to 30 gr., best given in a pill of 2 gr. every 2 hours. Like quinin, it produces a moderate effect on the circulation, and is in no way irritating. The author claims that it is effectual in some cases that resist quinin.

Bromic Intoxication, Certain Effects of.—Under this heading Weir Mitchell[6] discusses the unusual actions of the bromids which follow their excessive use. He says that the symptoms for which the drug was taken often

[1] Squibb's Eph., Jan., 1896. [2] Ibid.
[3] Am. Jour. Med. Sci., Apr., 1896, from Münch. med. Woch., 1895, No. 52, S. 1209.
[4] N. Y. Med. Jour., June 27, from Jour. des Pract., June 6.
[5] Brit. Med. Jour., Oct. 5, 1895, from Rev. de Cien. med., July 20.
[6] Am. Med.-Surg. Bull., May 16, 1896.

become much worse under its use, especially during menstruation. It causes delusions, suicidal tendencies, etc. Irritability of temper is a frequent result. It also has some effect on the urine. In chronic cardiac asthenia the symptoms grow worse. A tendency to ptosis is a common sequence. The author has also seen, during administration, the development of paresis and an inability to walk, sometimes more marked on one side of the body, resembling hemiplegia. In this respect it resembles the well-known effects of alcohol where it occurs that a man seems to be more drunk on one side than on the other. The left side was more commonly affected. The use of bromids also led to loss of memory, going on to partial paresis, with involuntary movements of the bowels. Janeway[1] has seen a number of deaths which could only be explained by the inordinate use of bromids.

Another drug in the same category is **bromosoda,** which drunkards make use of when they want to reform, and it is just in these cases of cardiac depression that the bromids are most dangerous. Hare in the discussion following dwelt with emphasis on the depressing effects of potassium on the heart and respiration, and expressed the opinion that these effects of potassium bromid might be due to the potassium as much as to the bromid. Dana, on the other hand, does not believe that potassium has anything to do with the depressing effects of potassium bromid, in which opinion Weir Mitchell seemed to concur: he uses lithium bromid when giving it alone, because it contains more bromin than any other form. Hare[2] pursues the subject with some warmth, and brings evidence and authorities which seem conclusive to the support of his opinion, that potassium salts are per se poisonous, and that the action of potassium bromid depends for its depressant effects on the potassium.

Potassium Bromid.—Taty[3] finds that the combination of potassium bromid with adonis vernalis and codein has not, in his experience, the favorable results claimed by Bechterew. The addition of codein seems to produce constipation and somnolence, which were not noted when this drug was absent. The adonis does not much affect the circulatory system, although the heart-beats seem less full and a little more frequent. The occurrence of the epileptic crises does not seem to have been influenced other than by the bromid alone, and the combination does not prevent the complications and disagreeable symptoms which arise during the administration of the potassium bromid.

Calcium sulphid is recommended as a prophylactic of influenza by Green;[4] 1 gr. daily was given during several epidemics, with the result that those treated seemed to acquire an immunity, while others under the same conditions, who did not receive calcium sulphid, were attacked. The author states that 3 days are required to saturate the system sufficiently to prevent infection, and the drug has less effect than quinin when taken after exposure; still, it does modify to some extent the course of the disease.

Carbolic-acid-poisoning, Alcohol as an Antidote in.—Fraser[5]

[1] Am. Med.-Surg. Bull., May 16, 1896. [2] Therap. Gaz., July 15, 1896.
[3] Ibid., May 15, 1896, from Lyon méd., Dec. 29, 1895, Jan. 5 and 12, 1896.
[4] Squibb's Eph., Jan., 1896, from Brit. Med. Jour., vol. i., for 1895, p. 974.
[5] Med. Rec., Nov. 23, 1895.

claims that the corrosive action of carbolic acid is greatly diminished if it is diluted with an equal quantity of alcohol. A woman who had attempted to commit suicide drank an unknown quantity of phenol in a glass of whisky, and suffered not at all from pain, nor were there any signs of corrosive action on the lips, tongue, or throat. The patient was in a profound stupor, with pupils contracted to pin-point size. The pulse was strong and regular, respiration undisturbed. There was slight jerking of arms and legs, with anesthesia of extremities. Almost constant vomiting followed this condition, lasting 24 hours, after which recovery was complete. The writer states that the local action of phenol may be so influenced by alcohol that the white stain and burning disappear entirely. Carleton[1] claims the same antidotal effect, as regards the skin and mucous membranes, for vinegar.

Carbon Dioxid, the Influence of, on the Sexual Organs.—Schuster[2] observes that the irritation of the skin produced by bathing in water containing carbon dioxid is manifested by a sensation of heat and prickling, with redness, especially pronounced about the genitals. This irritation, the author claims, may be used to stimulate the centers, spinal and cerebral, and is of use therapeutically in sexual debility not dependent on organic disease. It is contraindicated in spermatorrhea, but may be of service in precocious senile impotence. The use of carbon dioxid in the form of baths, douches, etc. is indicated in the anaphrodisia of women, and, according to the author, has been found useful in uteroovarian neuralgia, in dysmenorrhea, and amenorrhea.

Bitterless Cascara Sagrada.—According to Gilpin,[3] the researches of various investigators have proved that the laxative properties of the bark of this tree are undoubtedly due to principles similar in their medicinal properties, and to a great extent in their chemic composition, to those contained in rhubarb and frangula. Cascara sagrada differs, however, from rhubarb in the bitter principle which it contains. Meier and Webber assert that the drug also contains a ferment, to which is attributed the griping effects of the fresh bark, and the bark should be kept at least 1 year after its collection before being used, as is the rule with frangula-bark. The resinous constituents are probably the cause of the purgative action. Gilpin gives a method of making a powder which will contain all the resinous constituents, but which shall be free from bitterness. This powder may be used for making liquid preparations: Take of powdered cascara sagrada 500 gr.; licorice-root 110 gr.; magnesia (calcined) 10 gr.; powdered cloves 5 gr. The powders are thoroughly mixed, transferred to a "power-kneader," and then moistened with sufficient water; after being thoroughly kneaded the mass is transferred to a closed drying chamber and subjected to a uniform temperature of 180° F. for 48 hours. The moisture is then permitted to escape from the chamber and the powder thoroughly dried, after which it is repowdered and sifted.

Chlorids of Sodium and Potassium in Metabolism.—According to

[1] N. Y. Med. Times, Nov., 1895.

[2] N. Y. Med. Jour., from Gaz. hebdom. de Méd. et Chir., Apr. 16, 1896.

[3] Am. Jour. of Pharm., Mar., 1896.

Pugliese,[1] sodium chlorid in doses of 0.25–0.5 to the kgm. has in the dog no diuretic action; it causes an increase of weight, raises the coefficient of digestibility of protein, lessens nitrogenous metabolism, leads to a retention of the sodium salts on the part of the tissues, while bringing on an increased elimination of potassium; finally, it does not modify the elimination of the phosphates. Potassium chlorid in doses of 0.25 g. to the kgm. seems to have only a diuretic action. The chlorids of both sodium and potassium cause increased metabolism and hasten interchanges in the tissues. When given together, an increased elimination of sodium is soon apparent in the urine, while an accumulation of potassium takes place in the tissues. Sodium, concludes the author, is then a moderating element in metabolism, while potassium is an excitant.

Chinosol.—Ostermann[2] recommends this new compound as a disinfectant and deodorizer. It is said by the manufacturers to be made from potassium pyrophosphate, 25 parts; oxychinolin, 29 parts; alcohol, 120 parts. It is freely soluble in water. On boiling, a neutral sulphate of potash and neutral oxychinolin are formed. It is especially useful as a disinfectant and deodorizer of fetid ulcers and cavities. It is said to limit secretion and suppuration, and to be nonpoisonous and nonirritating: the author is convinced of the latter statement, as he has used it with success in gonorrhea in strong solution and in the form of gauze and the pure powder, in the abdominal cavity.

Chloral, a Chemic Antidote for.—Chloral is quickly decomposed outside of the body at and above 60° F. in an alcoholic solution of potassium into formate of potassium and chloroform, and somewhat less quickly in an aqueous solution of potassium. Dougall[3] therefore recommends the use of liquor potassæ as an antidote; 80 grains of chloral would require, theoretically, 27 gr. of potassium for its decomposition; this may be given as liquor potassæ, 112♏ every hour, reducing by degrees the dangerous quantity of chloral. The formate of potassium merely produces a peculiar eruption similar to that of chloral, while the chloroform would be exhaled as rapidly as produced. As the maximum dose of liquor potassæ is 60♏, the antidote must be given very well diluted in gruel, warm milk, or barley-water.

Chromic-acid Poisoning from the Vagina.—Sticker[4] reports a case in which, after a single application to the cervix of pure chromic acid, there ensued almost immediately collapse, suppression of urine, and frequent bloody stools. The urine contained much albumin, blood, and epithelium from the kidney. Recovery was slow, but complete.

Cocain-poisoning, with fatal result, is reported by Curgenven[5] after the ingestion of a solution containing 10 gr. of the salt. The bottle had stood for a year in a warm room, and the author suggests that the fatal result may have been due to the mould or to toxins generated thereby. [Although we cannot deny that this explanation of the cause of poisoning is possibly true, it is certainly improbable, to say the least.] Violent tetanic spasms, cyanosis,

[1] Univ. Med. Mag., Jan., 1896, from Arch. di Farm. e Terap., vol. iii. fasc. 7, July, 1895.
[2] Therap. Monatsh., Mar., 1896. [3] Therap. Gaz., July 15, 1895, from Glasgow Med. Jour.
[4] Münch. med. Woch., July 9, 1895. [5] Quart. Med. Jour., Jan., 1896.

shallow respiration, and a rapid and thready pulse followed the taking of the dose, and lasted 40 or 50 minutes until death supervened. Garland [1] describes a fatal case in which the patient swallowed ʒij of a 10% solution of cocain. She almost immediately afterward suffered from vertigo, followed by 9 epileptiform convulsions, and died within 40 minutes. The autopsy did not reveal the cause of death. This case, says the writer, lends support to the correctness of Mannheim's estimate that the fatal dose of cocain is about gr. xv. In the present state of our knowledge it is, however, practically impossible to state the smallest lethal dose, seeing that gr. $\frac{2}{3}$ has caused death, and so minute a dose as gr. $\frac{1}{100}$ has given rise to symptoms threatening life. Ingraham [2] used oxygen with success in a case where, after taking gr. x of cocain, the patient seemed moribund; the pulse was rapid and almost imperceptible, respiration shallow, the lips and extremities blue, and consciousness abolished during 18 hours, during which time morphin, atropin, and alcohol had been given without success; the lungs were becoming edematous. At this point oxygen-gas was first given, and the inhalations continued for 2 hours, when the patient regained consciousness and the general condition began to improve. The writer states that this case illustrates the cumulative action of cocain, as the poisoning followed gradual absorption of the drug. Pfister [3] narrates a case in which, after the injection of an unknown quantity of a 20% solution of cocain in the urethra of a patient who was young and, except for vesical calculus, possessed of good health, death followed almost immediately. This author gives the maximal dose as 0.05 gr., or about $\frac{4}{5}$ gr.; 4 drops of a 20% solution would contain this amount. Walker [4] reports a case of a man who had swallowed 8 or 9 gr. of cocain. The symptoms were constriction of the throat and region of the heart, great difficulty in swallowing, mental dulness, dilated pupils. He resembled a bad case of chorea; the movements, however, were slower and more regular. The body was alternately rotated from side to side and bent at the same time, while the arms and legs were never still. Amyl nitrite gave rapid relief, all of the symptoms disappearing in 5 or 6 hours.

Caffein and Theobromin.—Albanese [5] states that when caffein is administered to dogs in large doses by the mouth about 7% of it passes unchanged into the urine; 10% more is found in the urine as monomethylxanthin—a substance which, according to the author's researches, is to be considered as an intermediate product of the final transformation of caffein into urea and ammonia. Theobromin behaves in the same way, only in this drug the transformation is less rapid and less complete. In man the ingestion of tea or coffee produces a very sensible increase of the xanthin bases that are to be found in the urine, but it is impossible to detect either caffein or monomethylxanthin. With regard to this last substance, it is said to possess diuretic properties analogous to those of caffein, but to a more marked degree.

Coffee-poisoning.—Gilles de la Tourette[1] states that chronic coffee-poisoning is much more common than is supposed, and is generally confounded with alcoholic disturbances. The poison acts principally on the stomach and the nervous system. The coffee-dyspepsia resembles the alcoholic very much: there are, as symptoms, morning expectoration of mucus, pain in the epigastric region, and marked anorexia. The disgust for food finally becomes so great that the patient can only take coffee or bread soaked in coffee, and in this manner the poisoning rapidly increases in severity; nausea and vomiting, with acid pyrosis, next appear, and the patient becomes much emaciated. On the side of the circulation a slowing of the pulse is usually observed, palpitation being rare. The nervous symptoms are marked. Insomnia is common, or, if sleep occurs, it is often accompanied by terrifying dreams. General tremor is often present, with fibrillary twitching of the lips and tongue. Cramps in the limbs may occur. The general sensibility is diminished in a certain number of cases. Paralyses have not been observed. In children arrest of development takes place. The stoppage of the coffee generally results in a rapid cure—much more rapid than in alcoholism.

Cresochin.—Under this name a nonalkaline cresol disinfectant is prepared which is stated[2] to be a neutral combination of tricresyl sulfonate and quinolin with tricresol. It contains 33% of quinolin and 17% of tricresyl. It is not caustic, and is soluble to the extent of 1 in 25 in water. It is especially indicated as a disinfectant, since, being free from alkali, it does not set free ammonia from nitrogenous organic matter.

Cyanid-poisoning, Treatment of.—In a previous communication Lang[3] showed that cyanic acid, like formonitril, as also the much less dangerous acetonitril, is transformed in the body into the relatively harmless thiocyanic acid. The attempt is now made[4] to imitate and support this physiologic process. Among a number of agents tried, sodium thiosulphate antagonized successfully a dose of hydrocyanic acid 2 or 3 times the fatal strength in animals. If the poison was taken by the mouth and the antidote given subcutaneously, it was possible to render a dose 3 or 4 times that of the lethal dose harmless. Of other substances suggested as antidotes for this poison, potassium permanganate and hydrogen peroxid were unavailing. Cobaltum nitricum was efficient, but not more so than the thiosulphate of soda. [The description of the use of cobalt as an antidote for cyanic acid will be found on p. 1062 of the *Year-Book* for 1896.]

Digitalis and its Alkaloids.—As a result of recent experiments, Franck[5] concludes that digitalis acts equally on the two hearts, and not more strongly on the right, as claimed by M. Sunor, nor on the left, as English authorities assert. The author also asserts that an infusion of the leaves of digitalis produces a more marked action on the heart than a corresponding

[1] Am. Med.-Surg. Bull., Mar. 7, 1896, from Gaz. méd. de Paris, July 20, 1895.
[2] Druggists' Circ. and Chem. Gaz., July, 1896.

[5] Canad. Pract., Dec., 1895, from Gaz. des Hôp.

dose of digitalin. Koplik[1] writes of the uses and abuses of digitalis in pediatrics. There is no drug of greater utility, but the most gratifying effects are obtained from small doses rather than from the larger quantities. There are children, however, who react in a peculiar way. Some preparations of digitalis have no effect on these children in small doses, yet when the larger dose is given or a substitution made—as, for example, the powder replaced by the fluid extract—we have striking digitalis-effects shown by the action of the heart, and the administration of the drug must be suspended. The writer says these children should never receive digitalis in any form, as the drug is a direct cardiac poison to them. Two well-marked cases are given, 1 of scarlatinal nephritis, the other of pneumonia, showing the usual cumulative action of digitalis on the heart and persistence of the symptoms for 2 or 3 days.

Digitoxin.—Wenzel[2] has used Merck's digitoxin in a number of cases of valvular disease, myocarditis, and nephritis. In most of the cases there were disturbed compensation, engorgement of the pulmonary circulation, and marked diminution of the urine. The drug was always given by the rectum in the following manner: 15 g. of a solution of digotoxin .01, alcohol 10, aq. dest. 200, were administered in 100 g. of lukewarm water, at first 3 times, then twice, finally once daily; gr. $\frac{1}{188}$ then was given at each dose. In only 2 cases was an unpleasant result noted—vomiting, which soon ceased. The effect on respiration, pulse, quantity and specific gravity of the urine, and on the albumin present was very pronounced, even in cases in which other remedies, including digitalis, had been tried in vain. The method of administration reduces to a minimum disturbances of the alimentary canal. Corin[3] speaks with equal enthusiasm of the efficacy of this drug in pneumonia. It was given according to the following formula: ℞. Digitoxin (Merck), gr. $\frac{1}{20}$; chloroform and alcohol, *āā.* q. s. ad. solv.; aq. dest., ℥vij. Sig. One-third to be taken every 6 or 8 hours. Vomiting occurred only in 3 or 4 of the 53 cases treated, and may be prevented by not giving the drug in a concentrated form or in too large a dose. The author does not allow the patient to take food for an hour before or after administration of the drug. During the 2 years in which he has used digitoxin, Corin states that he has had no ill effects from it, and no sign of cumulative action. The indications for discontinuing its use are, as in digitalis, slowing and intermittence of the pulse, but it is not dangerous to continue the drug until intermittence begins. There is time to stop after this commences, as it occurs, at the most, 6 hours after the last dose. [Digitoxin would seem more nearly to represent the value of digitalis than any of the other principles of that drug, and its use appears to be growing more general. Compare *Year-Book* for 1896, p. 1035.]

Enuresis, Treatment of.—Nason[4] reports that a woman of 20 had suffered from the earliest childhood, scarcely ever missing a night, and on some

[1] N. Y. Med. Jour., Feb. 8, 1896.
[2] Therap. Gaz., Nov. 15, 1895, from Centralbl. f. innere Med., May 11, 1895.
[3] Therap. Woch., Aug. 11, 1895.
[4] Am. Jour. Med. Sci., May, 1896, from Brit. Med. Jour, 1896, No. 1832.

occasions wetting the bed 2 or 3 times in a single night. After the usual medication had failed a No. 10 catheter was passed into the bladder and connected by a tube with an irrigating basin containing a quantity of boric-acid solution. The basin being raised from 1 to 2 feet, the bladder was injected until the patient complained of slight pain. The positive electrode of a constant-current battery was applied over the lumbar spine, and the negative placed in the fluid in the basin; a weak current was then allowed to pass for 10 minutes. This was repeated every evening for 2 weeks, then at longer intervals. By this method it is said that a current of electricity would, after passing from the neighborhood of the lumbar cord through the vesical nerves, be evenly distributed over the walls of the distended bladder. The toleration of the bladder was rapidly increased from 4 oz. on the first occasion to 20 oz. at the end of a fortnight. After some months of treatment the urine could be retained for a much longer period, and for nearly 4 months the patient has been practically well. [The possible influence of suggestion in this case, in the absence of evidence to the contrary, must necessarily impress one.]

Erythrophleum.—Harnack[1] describes important changes in the hydrochlorate of this drug as compared with the specimen obtained from the same manufacturer and examined by him in 1882. At that time the action was that of digitalin and picrotoxin (clonic convulsions) in warm and cold-blooded animals. The recent preparation gives only the action of digitalin. The chemic reactions are also different. Formerly, the base, its salts, and double salts could only be produced in the form of a clear syrup; now the salt forms a fine, bright-yellow, amorphous powder. The new preparation of Merck seems to deserve consideration as a substitute for digitalis and strophanthus, as it raises the blood-pressure energetically and is not cumulative in its action. Neither the author nor the manufacturer is able to state wherein the difference lies. It seems probable, however, that the two specimens come from different kinds of bark or from different species of the same tree.

Eucain.—Kiesel,[2] a Berlin dentist, claims that this new artificial alkaloid, said to be the methylester of a benzoylated oxypiperidin carbonic acid, is as efficient as cocain in inducing local anesthesia, and in some respects is superior to that drug. The heart is in no way influenced; in very nervous patients, whose pulse had risen to 120 or 130 before the operation, the heart-beats become normal and regular very soon after the injection. The anesthesia is more extensive in area and lasts longer than that of cocain. In some experiments the effect extended even to the muscles. In a case in which an injection was made over the first incisor there occurred paralysis of the ala nasi and anesthesia of the nasal mucous membrane on the right side. The sense of smell was not interfered with. As much as 30 gr. may be injected without risk, while an equally safe dose of cocain is only gr. $\frac{1}{6}$. Solutions of 15% strength in sterilized water are permanent at the ordinary temperature of the room. They remain clear without the addition of an antiseptic, and do not become

[1] Berl. klin. Woch., Sept. 2, 1895.

[2] N. Y. Med. Jour., May 9, 1896, from Zahnärztl. Rund., Apr. 5, 1896.

flocculent, as does cocain. Finally, it is said that eucain will be obtainable at a price considerably lower than that of cocain.

Schleich[1] states that the alkaloid is soluble with difficulty in water, but that it forms an easily soluble hydrochlorate, which may be applied to the surface of mucous membranes or injected in solution of the strength of 1 : 6½. The area of anesthesia is said to be greater and the duration longer than when cocain is used. The most complete study of this drug that has yet come to hand is that of Dr. Gaetano Vinci.[2]

Two forms of eucain hydrochlorid—that crystallized from a watery solution and that from a methyl-alcohol solution—were used in laboratory and clinical experiments. The latter causes slight hyperemia and irritation, and is, apparently, not more efficient than the watery solution, which is preferable for practical use. A solution of from 2 to 5% instilled into the eye of a rabbit caused complete local anesthesia in from 1 to 3 minutes. It is stated that the pupil was not dilated and reacted to light, and that accommodation remained normal. The general action of the drug, both in cold-blooded and warm-blooded animals, consisted in a marked excitation of the entire central nervous system, followed by paralysis when toxic doses were given, going on to death. Even gr. $\frac{1}{33}$ caused irritability, heightened reflexes, incoordination, and finally general paralysis in animals. Small doses administered to mice and rabbits caused increased reflex excitability, and increased but weakened respiratory movements. Medium doses, of from $\frac{1}{3}$ to $\frac{1}{2}$ gr. to each 35 oz. of the animals' weight, caused repeated clonic and tonic convulsions. The animals lay senseless on their sides, with dyspnea, opisthotonos, and finally paresis of the posterior limbs. The animals finally died when the paralysis reached the respiratory muscles. When the dose was not a fatal one the convulsions gradually ceased, the increased reflex excitability disappeared, and the paresis of the hind limbs slowly improved. The author concludes that the effect of eucain on the central nervous system is at first exciting, then, in the case of toxic doses, paralyzing. The paralysis is a central one, for if the sciatic nerve of a frog poisoned with eucain is exposed and its peripheral end irritated with the induced current, the limb reacts in a normal manner. As regards its action on the heart and blood-vessels, the subcutaneous and intravenous injection of small and medium doses slows the heart's action, on the average, from 20 to 30 beats a minute, but without otherwise modifying the beats or increasing the blood-pressure. This effect on the pulse is caused by the excitation of the central vagus; for section of the vagi causes an immediate increase of the pulse to the normal and above it, together with an increase of the blood-pressure. Death occurs from paralysis of the respiratory center, for the heart continues to beat for some time afterward. In all these points, says the author, eucain is similar physiologically to cocain, but it is less poisonous. While the animals treated with eucain survived, those treated with the same doses of cocain died. The pulse with eucain is always diminished in fre-

[1] Am. Med.-Surg. Bull., June 6, 1896.

[2] N. Y. Med. Jour., June 20, 1896, from Deutsch. med. Zeit., Apr. 27.

quency; with cocain there is a primary acceleration. As regards their local action, the promptness of the anesthesia, its duration and intensity, there is no difference between the two substances. Eucain causes no ischemia; on the contrary, vascular dilatation occurs. A further difference, of great importance in ophthalmology, is that the pupils and accommodation are not affected. A later investigation conducted by Vollert[1] in Leber's clinic at Heidelberg does not substantiate the above in every particular. A 5% solution of eucain causes in the conjunctival sac a much greater irritation than cocain, the pain, lachrimation, and redness lasting 1 or 2 minutes. This followed the use of even a 1% solution. Anesthesia lasts from 8 to 12 minutes. There is hypotonos, as with cocain, and mydriasis, with paresis of accommodation. The chief obstacle to its use in ophthalmology is the injury to the corneal epithelium, which, according to the author, will prevent its substitution for cocain.

Exalgin.—Weber[2] reports an instance in which, after 1½ oz. had been taken, there were rotatory vertigo, blunted sensibility, contractures, and threatened asphyxia. Anuria persisted for 24 hours, and afterward the urine contained hematin, biliary pigment, and albumin. Recovery followed after vigorous stimulation, catharsis, and bloodletting.

Fat, Subcutaneous Injections of.—Mendel[3] describes Leube's method as follows: Professor Leube of Würzburg, in treating patients with a weak heart, incidentally observed that it was possible to make 20 or more injections of camphorated oil per day without calling forth any irritation of the skin or other disturbances. In an almost hopeless case 100 injections of the same oil were made per day on 3 different days, with excellent results, and attention was thus called to the fact that 80 to 100 g. of oil could be injected daily. Leube instituted a series of experiments on dogs, in which the body-fat had been reduced to a minimum, to ascertain whether fat subcutaneously injected in such animals could be assimilated. Butter was selected for his experiments, since this fat contains—in addition to palmatin, stearin, and olein—glycerids of the lower volatile fatty acids in considerable quantities. A dog was fed on lean meat daily until the animal remained of constant weight for 4 weeks, and an absence of body-fat could thus be assumed, as the dog appeared extremely emaciated. In addition to the continued feeding of meat, liquid butter of about body-temperature was injected daily beneath the skin of the limbs. A total of 2450 g. of butter was injected subcutaneously. On postmortem examination an abundant deposition of fat was found in the mesentery, about the heart and kidneys, as well as subcutaneous layers of adipose tissue in the region of the abdomen and back. The subcutaneous abdominal fat proved to be almost pure butter; the fat in the region of the back was about ⅓ and the pericardial fat about ⅙ butter-fats; that of the kidneys and mesentery, however, did not differ materially from ordinary dog-fat.

In a second experiment a dog, as before, was brought to constant weight and laparotomy performed; thus it was observed that fat was not present in

[1] Münch. med. Woch., 1896, No. 22. [2] Am. Jour. of Med. Sci., Feb., 1895.
[3] Am. Med.-Surg. Bull., Feb. 8, 1896, from Dietet. and Hyg. Gaz., xi., 1895.

the subcutaneous tissue, and that mere traces were to be seen in the mesentery. The wound was again closed and healed rapidly. In the following 1½ months a total of 1400 g. of fat was injected under the skin of the thigh, meat being fed as previously. During this time body-weight increased from 3.880 kilos to 5.360 kilos. A second laparotomy was performed, and it was now found that the subcutaneous abdominal tissue, as well as the mesentery, were abundantly supplied with fat. The wound was closed and a lean-meat diet alone was given; then the body-weight slowly decreased to 3.850 kilos. On postmortem examination there was found to be a complete disappearance of fat from the tissues. The experiment shows conclusively that the butter-fats subcutaneously injected were deposited in the tissues, and that the fat thus assimilated was completely utilized in body-metabolism. At the end of 3 months only traces of the 1400 g. of fat injected remained. Regarding the subcutaneous absorption of fat, Leube thinks it probable that this substance passes through the spaces of the connective tissue into the body-cavities, and thus farther.

Ferratin.—Marfori,[1] whose work was discussed in the *Year-Book* for 1896, publishes the results of some recent experiments upon the absorption of ferratin and its physiologic action. The amount that can be absorbed depends largely on the condition of the mucous membranes. Sulphuretted hydrogen slowly decomposes ferratin in the intestine, thus reducing the quantity absorbed. The large amount taken up after the administration of saline purgatives is due to a desquamation of the upper layers of the intestinal epithelium caused by the purgative, which exposes a thinner layer of young cells, through which absorption takes place more rapidly. The amount absorbed varied from 11% to 30% of the amount administered. Experiments on animals and clinical experience show that there is no danger in the continued administration of the drug.

Formalin in ½ to 2% solution is an effective deodorizer and disinfectant, and especially useful in syphilitic ulcerations. Munger[2] narrates 2 cases which show its usefulness in this direction.

Galactagogues.—Experiments made by Griniewitch[3] show that there are a few drugs which really increase the quantity of milk secreted, and are said not to act detrimentally upon it, the specific gravity being unchanged and the fat being even somewhat increased. The most efficient of the galactagogues examined by the author was a plant unknown in medicine, the common goat's rue, Gallega officinalis; a tincture containing 6.5% of the extract is made. The dose is 50 to 100 drops 5 times a day. The common stinging nettle, Urtica urens, is next in efficiency, and is given in doses of 250 to 500 drops daily of a 20% tincture of the extract. Cumin, anise, and fennel are also said to act on the secretion of milk, and may be given in powder, 15 gr. from 1 to 5 times daily.

Glycosuria after the Ingestion of Sugar.—Linossier and Roque[4]

[1] Univ. Med. Mag., Nov., 1895, from Arch. ital. de Biol., t. xxiii. fasc. i., ii.
[2] Am. Med.-Surg. Bull., May 16, 1896. [3] Ibid., Aug. 1, 1895, from Lancet, 1895, i. p. 1597.
[4] Quart. Med. Jour., July, 1895, from L'Union méd., 1895, No. 13, p. 150.

have experimented upon 19 persons, either in good health or with diseases not likely to affect their assimilation of sugar, to determine the limit and conditions of assimilation. Cane-sugar, glucose, and lactose were given. After the administration of cane-sugar there was either glycosuria or saccharosuria. The latter occurred in all cases, but the quantity required to produce it in each case was extremely variable; 50 g. produced saccharosuria in 29% of the cases, and none of them resisted 350 g. There was always a small amount of glucose with the saccharose. In certain of the subjects glucose formed a large part (as much as 89%) of the total sugar eliminated. This glycosuria, which occurred in 16% of those under observation, followed the ingestion of as small quantities as 50 or 60 g. of sugar. Of the 3 sugars experimented with, saccharose passed most freely into the urine, then glucose, and finally lactose. The authors conclude that for each person and for each sugar there is an individual "coefficient of utilization," increasing within certain limits with the quantity of ingested sugar. The test employed for saccharose consisted in the addition of Fehling's solution to 5 c.c. of urine, previously boiled after the addition of a drop of hydrochloric acid. [This has more than the physiologic interest pertaining to alimentary glycosuria (see *Year-Book* for 1896, p. 1095). From a clinical standpoint the fact that the ingestion of comparatively small quantities of sugar is followed by the appearance of glycosuria in 16% of healthy subjects suggests the necessity for diagnostic caution.]

Guaiacol[1] obtained from beechwood and other creasotes has varied so considerably in purity—all the way from 50 to 90%—that an incentive has been given to perfect the previously discovered process for making a synthetic product; this has been accomplished, and an article claimed to be absolutely pure is made on a commercial scale. It is now such an important article to the medical profession that it becomes a serious question to obtain a reliable article. In addition to the numerous references given last year to its various uses, its application in glycerin to nondiphtheric sore throat may be noted. Darbonet finds that the most intense sore throats run their course without fever or pain, the general condition of the patient remaining good throughout. As a local anesthetic Championnière[2] has used guaiacol in minor surgical operations. A dose of 10 cgm. dissolved in sterilized olive oil is sufficient to obtain anesthesia; 5 minutes should be allowed to elapse after the injection. The author claims a superiority over cocain, because much larger doses may be used with safety, no accidents being noticed except slight sloughing of the gums where it had been used for the extraction of teeth; this was attributed to a faulty method of injection or to a defective solution. Rogers[3] has used creasote or guaiacol in the treatment of malarial intermittent fevers; 15♏ were rubbed into the axilla and covered with cotton. The average fall of temperature in ¾ hour was 1.6°, in 1¾ hours 2.3°, and after 4 hours the average fall was 3°. The fall of temperature was accompanied by a free perspira-

[1] Squibb's Eph., Jan., 1896.

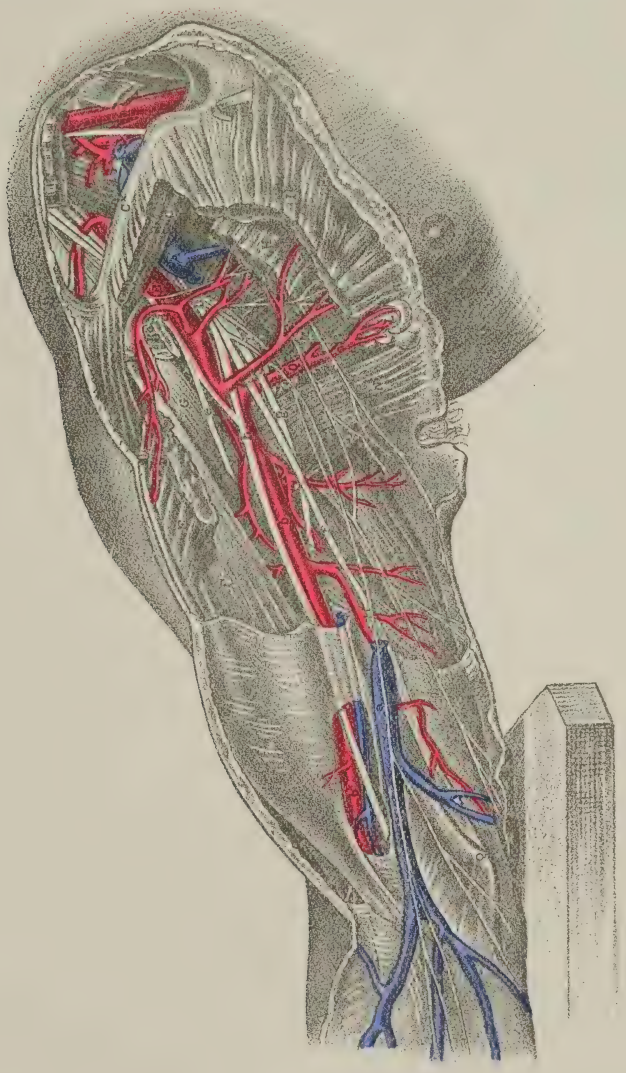
[2] Quart. Med. Jour., Sheffield, Oct., 1895, from Bull. de l'Acad. de Méd., July 30, 1895.

[3] Therap. Gaz., May 15, 1896, from Indian Med. Gaz., Jan., 1896.

tion and a marked improvement in the condition and comfort of the patient. No depression was noticed, and there is no mention of chills following the use of the drug.

Coghill[1] follows Schetelig's method of giving pure guaiacol subcutaneously in acute pulmonary tuberculosis; 3 hypodermic doses, 1 of 15 and 2 of 10♏, at 4 hours' interval, in 1 case brought the temperature from 104° to normal, with rapid amelioration of all the symptoms. Guaiacol is especially useful in what the author calls the fever of the suppurative stage of the disease. A moderate perspiration usually follows the injection, but no mention is made of depression or rigor. McCormick[2] denies that guaiacol is a depressant and a dangerous remedy where the circulation has suffered from long-continued fever. He has used it in a number of cases of typhoid fever with only the happiest results. He claims also that it is a most efficient intestinal antiseptic. The same author asserts that when given internally guaiacol does not reduce the temperature to the same degree as when applied to the skin. Guimard considers this action to be the product of a reflex through stimulation of the peripheral nerve-filaments and an action on the thermic center. The lowering of temperature is said to be almost inappreciable if the region to which the guaiacol has been applied has been previously anesthetized. It is probable, however, that its antithermic action is due to its rapid absorption by the skin, as in 15 minutes the taste of the drug is perceptible. [No doubt we have in guaiacol a remedy of much value, but, so far as our observation goes, its potency in tuberculosis is a disappointment.]

Guaiacol as an Anesthetic.—Newcomb[3] states that a 5% solution upon a pledget of cotton may be applied to the nose with complete anesthesia, and that it may be used in the ear when performing paracentesis. Smith[4] believes that all the coal-tar series have anesthetic properties.



Guaiacum.—Sir Alfred Garrod[5] considers this drug valuable in many gouty and rheumatic conditions. His views are summarized thus: 1. Guaiacum is innocuous, and may be taken for an indefinite length of time; 2. It possesses considerable power, but less than colchicum, in directly relieving patients suffering from gouty inflammation of any part; it may be given whenever there is but little fever; 3. Taken in the intervals of gouty attacks, it has a considerable power of averting their occurrence; in fact, it is a very powerful prophylactic; 4. It does not seem to lose its prophylactic power by long-continued use; 5. There are a few patients who cannot readily continue its use; for such cases there are other drugs whose action is in some respects similar, of which serpentary is one of the best. Garrod does not believe that guaiacum affects the formation of uric acid, but that it acts directly on the kidney as a stimulant, enabling it to get rid of any accumulation in the tubules, thus preventing absorption from them into the blood. In confirmation of this view patients when taking guaiacum often have unusual deposits of urates in their

MR. SAUNDERS is pleased to announce that he has ready his

NEW AID SERIES OF MANUALS

— FOR —

Students and Practitioners.

AS publisher of the "**Standard Series of Question Compends,**" and through intimate relations with leading members of the medical profession, Mr. Saunders has been enabled to study progressively the essential **desideratum** in practical "self-helps" for students and physicians.

This study has manifested that, while the published "Question Compends" earn the highest appreciation of students, whom they serve in reviewing their studies preparatory to examination, there is special need of thoroughly reliable handbooks on the leading branches of Medicine and Surgery, each subject being compactly and authoritatively written, and exhaustive in detail, without the introduction of **cases** and foreign subject-matter which so largely expand ordinary text-books.

The Saunders Aid Series will not merely be condensations from present literature, but will be ably written by well-known authors and practitioners, most of them being teachers in representative American Colleges. This **new series,** therefore, will form an admirable collection of advanced lectures, which will be invaluable aids to students in reading and in comprehending the contents of "recommended" works.

Each Manual will further be distinguished by the beauty of the **new** type; by the quality of the paper and printing; by the copious use of illustrations; by the attractive binding in cloth; **and by the extremely low price at which they will be sold.**

For further particulars, address

W. B. SAUNDERS, Publisher,
925 WALNUT ST., PHILADELPHIA.

urine. Murrell supported Garrod's conclusions as to the efficacy of guaiacum in chronic gout. He has used it for the last 6 years, not only for chronic gout, but for rheumatism, tonsillitis, and chronic bronchitis associated with a gouty taint. He favors the use of a confection. Haig agreed that guaiacum tends to ward off gouty manifestations, but could not accept the explanation of the way in which the drug acted. Potassium iodid causes diuresis and dilatation of all the blood-vessels, with a fall of blood-pressure. Lithia and ammonia have a similar action, as also has copaiba, tar, cannabis indica, certain salts of calcium, and certain bitters, such as chiretta, gentian, and possibly serpentaria. Copaiba contains a large quantity of acid, and guaiacum agrees with it in this. Haig believes that these drugs diminish the excretion of uric acid and keep the blood clear of it. Ewart thought that the action of guaiacum upon the capillaries was not limited to the kidneys, but extended to the whole system, and in particular to the capillaries of the muscles, as the effect of this drug in relieving painful manifestations located in the muscles is well known.

Hydroxylamin Hydrochlorate.—Lauder Brunton[1] suggests this drug as a substitute for nitroglycerin and the nitrites, as it has a similar action, but of longer duration. It is ammonia in which 1 atom of H is replaced by HO. It is known only in aqueous solution as salts, of which the most common is the hydrochlorate; this occurs in odorless crystals which are freely soluble in water. It converts hemoglobin into methemoglobin, and is said to be a powerful antiseptic.

Iodoformin.—Eichengrün[2] claims that this substance, the composition of which is not given, contains 75% of iodoform in chemic combination. It is a fine, white, odorless powder which when exposed to light becomes light yellow without being chemically changed. It is insoluble by ordinary means, but may be used in gauze and cotton and in salves where there is no water. It may be sterilized at a high temperature. On contact with acids or alkaline fluids, as in wounds, iodoform is set free. The author has also another similar preparation, iodoformal, for which nearly the same properties are claimed.

The Pharmacology of the Ipecacuanha Alkaloids.—Wild[3] continues the examination of the two alkaloids, cephaëlin and emetin, begun by Paul and Cownly.[4] Cephaëlin is soluble in caustic alkalies, emetin is not; the latter is identical with the emetin formerly obtained by Glenard.[5] These alkaloids possess a definite composition, agreeing with the formula $C_{14}H_{20}NO_2$ for cephaëlin and $C_{15}H_{22}NO_2$ for emetin; the latter alkaloid is thus the methyl compound of the former, the chemic relations between them being similar to that existing between morphin and codein or between caffein and theobromin. In the experiments the hydrochlorids of the alkaloids were used. Both cephaëlin and emetin possessed a powerful emetic action; the emetic dose of the latter was, however, about double that of the former. In nonemetic doses the

[5] Ann. de Chim. et de Phys., series 5, vol. viii. p. 233.

degree of nausea produced by cephaëlin was also about double that produced by emetin—*e. g.* the intensity and duration of the nausea following 5 mgm. of cephaëlin was much the same as that following 10 mgm. of emetin. Both alkaloids lowered the arterial tension, and little difference was apparent in small doses, but the depression produced by the emetic dose of cephaëlin was less than that produced by the larger dose of emetin; cephaëlin appeared, therefore, to be distinctly preferable where a nondepressing emetic was desired. Both alkaloids caused contraction of the blood-vessels after destruction of the brain and spinal cord, but emetin was distinctly more active than cephaëlin; 1 in 10,000 of the latter produced little if any effect, while 1 in 20,000 of emetin was followed by marked contraction. On the heart no appreciable difference could be made out; both produced slowing, weakening, and diastolic arrest of the isolated organ; recovery was easily effected when the poison was removed. It is doubtful whether the drugs in the doses administered to men would affect the heart directly; but the fact that 1 in 20,000 caused diastolic arrest in 46 minutes renders caution necessary in giving larger doses of the alkaloids. Both acted as muscle-poisons, but cephaëlin had the greater toxic power, and also caused irritation of the motor nerve-endings and contracture. Salivation was well marked wherever there was nausea. Emetin caused a flow of watery mucus from the nasal mucous membrane when a full dose was given; this was not noticed after cephaëlin. It is possible that the expectorant action of ipecacuanha is due to a similar action of emetin upon the other portions of the respiratory mucous membrane. Intestinal peristalsis and a loose motion at times followed the administration of either alkaloid; there was never any marked purgation. No effect was noticed upon the secretion of the skin or upon the amount of urine. Assuming the view that emetin is methylcephaëlin to be correct, it would seem that the chief effect of the addition of the CH_2 group was to markedly reduce the action of the compound upon the convulsive or vomiting center in the medulla, and also to diminish the irritating effect upon motor nerve-endings. The methyl compound had, on the other hand, a more powerful action as a local vasoconstrictor. The addition of the methyl group did not appear to affect the other actions of the alkaloid. With regard to therapeutic use, only accumulated clinical experience can determine their relative positions. It seems probable that in cephaëlin we have a powerful and certain emetic singularly free from depressing effects when given in doses of from 5 to 10 mgm. (from $\frac{1}{12}$ to $\frac{1}{6}$ gr.); its action, however, is too slow to prove of much service in cases of poisoning, but in all other cases where emesis is desired it appears well worthy of trial, In acute catarrhal and febrile conditions, as an expectorant, and for all uses of ipecacuanha where vomiting is not desired, emetin in small doses seems likely to prove of considerable value, and also as an emetic in larger doses of from 10 to 20 mgm. (from $\frac{1}{6}$ to $\frac{1}{3}$ gr.) when a more depressing action is required. The powerful local constricting effect upon blood-vessels may also prove useful in hyperemic and inflammatory conditions. The wide variations in the activity of the pharmacopeal preparations of ipe-

cacuanha may not unlikely be due to variations in the quantities and relative proportions of the alkaloids which they contain, and the use of the pure alkaloids may render one of our most valuable remedies of still greater service.

Iron.—Chittenden[1] discusses the question whether the iron contained in ordinary inorganic preparations is absorbed from the intestine and is utilized in the formation of hemoglobin. Kunkel's results, confirmed by Woltering, indicate that this is the case. Whether inorganic iron is as readily utilized by the body in the production of hemoglobin as organic iron, such as ferruginous nucleoalbumins, hematogens, etc., is a question not considered in Kunkel's work, but it is clear that the animal body can make use of inorganic iron in the absence of more favorable material to work with. Bunge's hypothesis, advanced at the recent Congress für innere Medizin at Munich, that the organic preparations of iron were not assimilated, and that the inorganic preparations were not even absorbed, but found in toto in the feces, is criticised by Reinert,[2] who refutes the startling conclusion that the results of treatment by iron must be referred to the domain of suggestion, and that a diet rich in iron, particularly meat, eggs, spinach, etc., should be substituted for the usual method of administration. Bunge's experiments with iron were all made on animals. Reinert says we should expect a difference in the absorption and assimilation of iron between healthy and chlorotic subjects, and he is not acquainted with an idiopathic chlorosis in the animals experimented on analogous to that in man. (Compare the *Year-Book* for 1896, p. 1043.)

DaCosta[3] has found iron administered hypodermically very useful in certain forms of anemia when a rapid effect was desired or when iron was not tolerated by the alimentary canal. After trying various preparations, the author concludes that the ferrous manganese citrate, made by Merck, gives the best results. The solutions are made thus: The crystals are powdered in a mortar and gradually dissolved in hot distilled water, gr. j of the crystals to ♏v of water. The usual dose for an adult is ♏xv, representing gr. iij of the compound salt. "The dose of iron for hypodermic use should not, to begin with, be more than ½ of what is given by the mouth. It gets rapidly into the circulation. Rosenthal[4] injected 0.04 g. of the pyrophosphate in solution into his own thigh, and 30 minutes afterward found the iron present in the urine." The effect on the nervous system of iron used subcutaneously is described as a sense of strength and excitation, in some cases where large doses have been given amounting even to delirium. Of this the author has seen no instances, nor has fever followed its use except in 1 doubtful case, the history of which is given. "Iron should not be used in this form indiscriminately, but only where rapid action is needed, as after exhausting hemorrhages or in anemic persons with delicate digestion who cannot assimilate iron by the stomach at all, or in gastric ulcer where it is desirable to prescribe iron, or when iron given by the mouth constipates excessively, or when a decided action on the

[1] Therap. Gaz., Mar. 16, 1890, from Dietet. and Hyg. Gaz., Nov., 1895.

[3] Therap. Gaz., May 15, 1896. [4] Wien. med. Presse, Dec. 1, 1878.

nervous system is required, and one that shall be produced as quickly as possible." Rocci[1] claims that iron administered in this manner remains in the organism as an assimilable substance, producing hyperemia in various organs and tissues, favoring the absorption of edema in anemic patients, the destruction of old red blood-corpuscles, and the formation of new hematins. As the author says, if this be true, the effect of hypodermic injections will be much more lasting than that following other forms of administration.

Izal is one of the numerous preparations of cresol, such as creolin, lysol, solutol, solveol, tricresol, etc. All of these productions are said to be superior to phenol in antiseptic properties, and far less poisonous. According to Squibb,[2] izal has no disagreeable odor, is a nonirritant, and does not affect instruments. It makes a cloudy solution. Delépine[3] considers this substance one of the most deserving of the disinfectants and antiseptics which have been proposed of late years. Izal may be freely administered internally, used over extensive wounds, and injected under the skin without bad effects. Numerous experiments with the most important types of pathogenic bacteria under varying conditions were made, and it was found that, diluted with 100 or even 200 parts of water, it is a powerful and reliable antiseptic when contact of a sufficient length of time is secured.

Kosotoxin is the name given by Leichsenring[4] to one of the active principles of kousso- (koso-) flowers, which he has isolated from the ethereal extract of the latter. He found them to contain about $1\frac{1}{2}\%$ of this principle. Kosotoxin occurs as a yellowish-white powder which is readily soluble in alcohol, ether, chloroform, benzol, carbon disulphide, or acetone, but insoluble in water; it is soluble also in aqueous solutions of the alkaline carbonates; melting-point, 80° C. Its physiologic action has been investigated by Dr. Handmann,[5] who has found that the substance is a strong muscle-poison, while it has but little influence on the central nervous system.

Lycetal.—This drug, which is dimethyl piperazin tartrate, is said by Anthony[6] to have certain advantages as a solvent of uric acid over the alkaline salts of lithium, sodium, and potassium. The author asserts that it dissolves not only the outer layers of uric acid, but disintegrates and removes the albuminous nucleus. It is said to be more diuretic than piperazin because of its composition. The dose is from 15 to 45 gr. in aqueous solution. Six cases are briefly reported.

Malt-extracts.—The question so often asked, whether these proprietary articles, so much in vogue at present, have any medicinal value, has been partly answered by Emanuel.[7] It has been claimed that their chief value lay in the presence of diastase; this the author finds, after a careful examination of 6 of the most popular malt-extracts, to be absent, not even a trace being present.

[1] Sixth Italian Congress of International Medicine, Rome, Univ. Med. Jour., 1895, p. 366.
[2] Eph., Jan., 1896. [3] Ibid., from the Med. Chron., Manchester, vol. iii. p. 434.
[4] Am. Med.-Surg. Bull., Mar. 21, 1896, from Pharm. Zeit., 1896, vol. xli. p. 60. [5] Ibid.
[6] Am. Jour. Med. Sci., Mar., 1896, from the New Eng. Med. Monthly, 1895, No. 9, p. 417.
[7] Am. Jour. of Pharm., July, 1896.

The alcohol varied from 1.75 to 6%, and the conclusion reached is that they are nothing more than a strong beer. Elsner[1] says: "A good malt-extract should be able to convert its own weight of starch into sugar, at a temperature of 55° C., in not more than 15 minutes." According to an authority quoted by the author, beer should be a fermented infusion of hops and barley-malt. Good lager beer should have a specific gravity of 1.0159, and contain 3.5% of alcohol and 5.5% of extractive. The extractive consists of the soluble part of malt and hops, partly unchanged and partly converted into decomposition-products; among the former are maltose, gum, dextrin, peptone, hop resin, and alkaloidal substances; among the latter, glycerin and fatty acids. The malt-extracts examined contained from 2 to 3 times as much extractive as the specimen of beer examined at the same time, and it would seem that if clinical experience places any value on malt-extracts other than that which a strong beer possesses, it must be attributed to their presence.

Mercuroiodohemol.—The use of this drug as an alterative and hematinic is advocated by Mann.[2] It is an odorless brown powder insoluble in water. It is said to contain, besides hemol, 13% of metallic mercury and 28% of iodin. It is best given in pills, 2 or 3 gr. each, 3 times a day. The author has used the drug in various forms of syphilitic disease, and has found it to be a mild mercurial, the action of which is increased by the iodin, and of especial value in anemic and cachectic conditions. The symptoms of mercurialism were limited to slight swelling of the gums and diarrhea, which disappeared promptly on discontinuing the drug. In the great majority of cases mercuroiodohemol was given continuously with no ill effects.

Nosophen is prepared by Classen and Löb[3] by treating a solution of phenolphthalein with iodin. Its chemical name is tetraiodophenolphthalein. It is a pale yellow, odorless, and tasteless powder, insoluble in water and acids, slightly in alcohol, but readily soluble in ether, chloroform, and the alkalies, and contains about 60% of iodin. It is acid in reaction, and forms salts with many of the ordinary bases. Its bismuth-salt is known by the name of eudoxin, and the sodium salt by the name of antinosin. After numerous experiments with this substance, internally and hypodermically applied, no toxic effects were noticed. Seifert[4] of Würzburg reports that it has marked desiccating and antiseptic properties, and is useful as an insufflation in the treatment of acute coryza, chronic rhinitis with hypersecretion, balanitis, soft chancre, and eczema. It is especially adapted, from its comparative insolubility and freedom from odor, to the after-treatment of operations on the nose. It is said to prevent suppuration and the formation of adhesions after the application of the chemic or galvanocautery. It causes no irritation and no secretion in rhinitis sicca. The author states that it is more efficient in rhinitis hypersecretoria than bismuth, europhen, aristol, or sodium sozoiodolate. The sodium salt is soluble, and has been found to prevent the development of the

[1] Hülfsb. f. Chem., Apoth., u. Gesundheitsbeamt.

[3] Squibb's Eph., Jan., 1896. [4] Ibid.

anthrax-bacillus, staphylococcus, pyogenes aureus, and the diphtheria-bacillus within an hour. It has been used by Prof. Posner as an irrigation in cystitis in a 1% solution, but is not well borne in all cases. Eudoxin, the bismuth salt, has been used with some success by Rosenheim[1] in 26 cases of intestinal catarrh, principally chronic. Its good effects are attributed largely to its antifermentative action, and to the fact that it does not derange the stomach, even in dyspeptics.

Nicoulin.—The physiologic action of this substance, the formula of which is C_3H_4O, has been studied by Boinet.[2] It causes at first a period of excitation of the nervous centers, which are frequently congested. This short period of excitation is characterized by a temporary agitation, a few convulsive movements, acceleration of the respiration and of the heart's action, and meiosis in a very slight degree. These transient symptoms are especially marked in frogs, and are of variable duration according to the dose. If this was large, dulness, torpor, and stupor soon appeared, followed by paralysis of the muscles and sensation, disappearing later. With too large a dose death was preceded by a few convulsions. The mydriasis was marked in the last stage. The rectal temperature of the rat and of the guinea-pig fell to 86° and even to 77° F. The author says that the drug also caused secretory, respiratory, and cardiac symptoms which showed its predominant action on the bulb and its stupefying action on the nervous centers. The toxic doses varied. Nicoulin might cause death in doses of 0.062 gr. to 130 or 150 gr. of the animal's weight. If, however, the drug were administered in divided doses, of 0.031 gr. each, every 10 minutes, it would be eliminated in proportion to the dose taken. This fact led the author to make use of its stupefying and paralyzing properties in acute tetanus.

Nitroglycerin.—Mikhalkine has used this remedy successfully in sciatica where the usual remedies failed.[3] He claims that it has powerful antineuralgic properties. It is given in the following mixture: Alcoholic solution of trinitrin, 1%, 80 gr.; tinct. of capsicum, 120 gr.; peppermint-water, 240 gr. Five or ten drops to be taken 3 times a day. [That nitroglycerin may in some cases relieve sciatica is no doubt true, but that its pure and simple antineuralgic powers are great is a mistake.]

Nucleins.—Chittenden[4] gives a summary of the present knowledge of this subject. In the main, the opinions expressed are similar to those of Vaughan (*Year-Book* for 1896, p. 1051), and the advancement toward a more thorough acquaintance with the chemic properties of these complex bodies has not changed the clinical attitude of uncertainty. Chittenden divides nuclein bodies, provisionally, into 5 groups: 1. Nucleic acids, bodies rich in phosphorus, which contain no proteid matter, and yield on decomposition only phosphoric acid, nuclein bases, and sometimes carbohydrate bodies. They may occur free in some animal cells, as in spermatozooids, but are more generally united with more or less proteid matter. To this group may be added

[1] Squibb's Eph., Jan., 1896. [2] N. Y. Med. Jour., from Presse méd., Apr. 22, 1896.
[3] Squibb's Eph., Jan., 1896. [4] N. Y. Med. Jour., Apr. 11, 1896.

paranucleic acid, which, however, must have a widely different constitution, in that it does not yield any nuclein base on decomposition. 2. True nucleins, such as are present in cell-nuclei either as such or joined to proteid matter as a part of more complex molecules (nucleoproteids), containing variable amounts, as well as variable kinds, of nucleic acids, and yielding by decomposition proteid matter, nuclein bases, and phosphoric acid. 3. Paranucleins, obtainable especially from nucleoproteids with a low content of phosphorus, such as are present in the cytoplasm of the cell, in egg-yolk, and in milk. Paranucleins yield on decomposition proteid matter and phosphoric acid, but little or no nuclein bases—*i. e.* they are compounds of proteid matter with a small amount of paranucleic acid. 4. Nucleoproteids or nucleoalbumins, phosphorus containing proteids, widely distributed through all animal cells, which by digestion with pepsin acid yield soluble proteid products and true nuclein, the latter giving on further decomposition nuclein bases. 5. Paranucleoproteids, phosphorus-containing proteids, which by digestion with pepsin acid yield insoluble paranuclein, together with soluble proteoses and peptones.

The phosphorus so characteristic of all nucleins belongs to the contained nucleic acid, and may be taken as a measure of the content of nucleic acid. Further, a study of the cleavage-products of nucleic acid—as obtained from yeast, for example—shows that the peculiar nuclein bases formed in the decomposition of nucleins are likewise derived from the contained nucleic acid; hence we arrive at the conclusion that the typical element of all nucleins or nucleoproteids is the contained nucleic acid. Nucleic acid may be prepared from any form of nuclear material, preferably, however, from yeast-cells, as described by Vaughan;[1] it is an amorphous white powder of strong acid reaction, readily soluble in water containing a small amount of alkali; insoluble in alcohol and ether. From an alkaline solution it is not precipitated by excess of acetic acid, but is readily thrown down by a slight excess of hydrochloric acid, especially in the presence of alcohol.

Particularly noteworthy is the fact that nucleic acid in acid solution yields with albuminous bodies precipitates having the general character of nucleins. If we examine the composition of a few of the nucleoproteids and nucleins that have been separated from different tissues and organs, we gain a very clear idea of the great variation in the proportion of nucleic acid and proteid matter in these compound bodies. Thus, the peculiar nucleoproteid separated by Hammarsten from the pancreas contains 4.48% of phosphorus; the nucleus of yeast-cells Kossel found to contain about 6.19% of phosphorus; the nuclein of egg-yolk, according to Bunge, contains 5.19% of phosphorus; the peculiar nucleoproteid (nucleohiston) separated by Lilienfeld from the nucleus of lymphocytes contains 3.02% of phosphorus, while in the cytoplasm of leukocytes from the thymus and lymph-glands the same investigator found only 0.43% of phosphorus. Probably the great majority of the organs of the body contain nucleoproteids with a comparatively small percentage of phosphorus. The author gives the results of his examinations of 3 of the preparations

[1] Loc. cit.

on the market which are said to contain these substances. One, which is said to be made from thyreoid and thymus-glands, contains no phosphorus, therefore may be assumed to contain no nuclein. One form of a second preparation contains 1.25% of phosphorus, while another form of the same preparation contains only 0.22%. In a third preparation there was found a large percentage of phosphorus. As to the exact therapeutic action of nucleinic acids, nucleins, and nucleoproteids time and experience alone can determine.

Nutrose.—Bornstein[1] relates the results of his experiments with this sodium salt of casein, which may be thus summarized: 1. Nutrose is tasteless; 2. It does not irritate the intestine and is entirely absorbed; 3. It is completely utilized in the economy, and 4. It is not dearer than peptones, especially the Liebig's, with which the author compares it, and is much cheaper than somatose. These results substantiate the claims made by Salkowski[2] as a result of his experiments on dogs, that peptone preparations might well be replaced by casein.

Orthomonochlorphenol has been recommended by Munger[3] in atrophic and ulcerative rhinitis and eczema alæ nasi. The secretion and crusts were lessened promptly and excoriations healed kindly. A 25% solution was used in glycerol, but this should be applied by the physician only, and made fresh when needed. The drug is said to be useful in ulcerations of the septum and turbinated bones and in atrophic rhinitis. Berens[4] and Gleitsmann[5] speak of the anesthetic properties of this drug.

Parachlorphenol.—Girard[6] states that this product is crystalline at ordinary temperatures, has an odor similar to phenol, and is very soluble in alcohol and ether, though but slightly in distilled water, which takes up only 1.3%. With the addition of a small quantity of alcohol a 2% solution may be made. It coagulates albumin, as does phenol, but not completely. According to Karpow, in 2% solution it is a little less energetic than mercuric chlorid, 1:1000, against the spores of anthrax, but is incomparably more active than 5% solutions of phenol and cresol, and is much less poisonous than these substances. From the use of this antiseptic in about 200 operations the following conclusions are reached: In from 1 to 2% solutions it is the most energetic antiseptic which organic chemistry furnishes; it is of definite chemic combination, and in solution is almost colorless and with an odor less disagreeable than other phenol or cresol derivatives. It can be used for disinfection of the hands and instruments.

Paraldehyd in Asthma.—Hearder[7] calls attention to the antispasmodic action of this drug in asthma. He has used it, as he says, with good effects in about 30 cases, including ordinary spasmodic asthma, asthma with epilepsy, with heart-disease, with renal disease, with chronic bronchitis, and in 2 cases with pneumonia. In the majority of these cases relief was rapid

[3] Am. Med.-Surg. Bull., May 16, 1896. [4] Ibid. [5] Ibid.
[6] Am. Jour. Med. Sci., Feb., 1896, from Rev. méd. de la Suisse Romande, 1895, No. 7, 365.
[7] N. Y. Med. Jour., Apr. 11, 1896, from Brit. Med. Jour., Mar. 21.

and complete, and in the remainder the distress was lessened. One dose was usually sufficient; a few patients needed a second dose, however, of from 30 to 45♏ an hour or so later. The hypnotic action of the drug is also of great service, as in so many cases the attack comes on in the evening or during the night. A point in dispensing is that the addition of a few drops of alcohol renders paraldehyd perfectly miscible with water. Any flavoring tincture may be used for this purpose.

A New Disinfectant from Petroleum.—Bartochevitch[1] writes of a product of the distillation of petroleum which remains as a residue after the separation of benzin, paraffin, vaselin, etc. It possesses strong antiseptic properties and is well adapted for disinfection. It is prepared in the following manner: To 100 parts of the residue of petroleum 20 parts, by volume, of concentrated sulphuric acid are added; the mixture is shaken, and left in a cool place for 24 hours. At the end of this time there is a blackish opalescent liquid, forming two-thirds of the original mixture, and a precipitate resembling tar. The liquid is decanted, and to it is gradually added a 10% solution of potassa. The quantity of the solution added should be somewhat less than that of the liquid taken. The mixture is shaken until a homogeneous yellowish-brown, soapy liquid is obtained. From this fluid a 5% emulsion may be made which has weakly antiseptic properties, and may be used for disinfecting rooms, wooden and metallic objects, etc. The author states that the concentrated fluid kills pathogenic bacteria in 40 minutes. If added in the proportion of 10% by weight to fecal matter, the odor is removed and disinfection accomplished. The advantages claimed by the author are the absence of odor, nontoxicity, and cheapness of production.

Phenacetin-poisoning with fatal result is so rare an occurrence that a case reported by Krönig[2] deserves notice: A printer's apprentice, aged 17, received 3 weeks before admission to the hospital 5 phenacetin powders of 15 gr. each. These were taken at intervals, not more than 2 on the same day, for occipital headache. When first seen there was unusual pallor, which the physician attributed to chronic lead-poisoning because of the patient's occupation. At the end of 3 weeks, as the pain was no better, the same prescription was repeated. A few hours after taking 1 powder there was frequent vomiting. Early the next morning the patient became extremely weak; the face and lips were bluish gray; the temperature 102°, the pulse weak; there were vomiting and diarrhea; the urine was of a chocolate color, the conjunctivæ subicteric, and the abdomen sensitive to pressure. There was pus in the right auditory canal. The icterus increased, as did the cyanosis of lips and extremities, until the skin became peculiarly yellowish-gray in color. The bladder emptied by catheter contained almost pure blood, the cells being disintegrated, forming microscopically coarsely granular masses. Although the patient was moribund, he was able to assert with positiveness that he had taken only phenacetin; one of the powders remaining proved on examination to consist

[1] Am. Med.-Surg. Bull., Apr. 18, 1896, from La Sem. méd., 1896, xvi. p. 18.

[2] Berl. klin. Woch., Nov. 18, 1895.

only of that drug. The diagnosis was phenacetin-poisoning with probable sepsis. The autopsy showed essentially universal methemoglobinemia. The examination of the blood was most thorough, and deserves extended notice. The author states that the appearance of the patient reminded him of a fatal case of potassium-chlorate-poisoning which he had seen recently, and the appearance of the blood strengthened the resemblance. There was an increase in the white cells and a solution of the red cells, a true erythrolysis; poikilocytosis was also present; some cells still contained hemoglobin which had lost its staining property. In other cells there was a varying degree of extraction of the hemoglobin. In the first stage the cells were swollen, and showed at one part a protrusion in which lay one or more small masses of hemoglobin; later the hemoglobin became finely granular, either diffused or in streaks occupying the edges of the cells. The hemoglobin escaped from the cells during these stages, and remained free in the blood-current, to be taken up later, presumably, by one of the large glandular organs (liver, kidneys, spleen), or to be excreted, or, as was frequently observed, to be absorbed by the white cells. The red cell itself shrank and remained as a clear cell-cadaver. As regenerative forms appeared nucleated red cells in the shape of normoblasts and megaloblasts. The author states that this condition was present also in the case of potassium-chlorate-poisoning mentioned above. All of the lesions found at the autopsy which contributed to the sudden and fatal termination must, in the opinion of the author, be attributed solely to the action of the phenacetin upon a subject whose powers of resistance were weakened by a low septic condition.

In the discussion following A. Fränkel mentioned 1 fatal case of phenacetin-poisoning that had come to his notice. Fürbringer had seen the symptoms of profound collapse follow a dose of 8 gr. of lactophenin. Aronson and Gerhard agreed with what had preceded, and added an emphatic warning against the careless and indiscriminate use of antipyretics of this class. The latest contributions to the literature of this subject may be found in "Die neueren Arzneimittel," Löbisch, 1895.

Phenylhydroxylamin-poisoning.—Hirsch and Edel[1] report the first case of poisoning by this body, which was produced last year, and has been recently examined by Lewin.[2] It is a product of nitrobenzol by reduction with tin; formula, C_6H_5NHOH. Lewin says: "I have examined most of the blood-poisons, and know of none that acts so quickly and in such small quantities as phenylhydroxylamin." In this instance poisoning followed absorption through the unbroken skin. A student in the laboratory spilled a quantity of the substance in alcoholic solution over his legs. This caused an intense burning pain, but no lesion of the epidermis except a brownish discoloration in places. In 20 minutes he became comatose, with extreme pallor and blue lips; he lost corneal and pupillary reflexes, and had an imperceptible pulse; respiration was deep and stertorous, but regular and not rapid. While the muscular tone as well as the skin-reflexes and tendon-reflexes were much

[1] Berl. klin. Woch., Oct. 14, 1895. [2] Arch. f. exp. Path. u. Pharm., Bd. xxxv.

diminished, the arms were held in tonic flexion. In 4 hours, after constant stimulation and venesection, followed by the subcutaneous injection of a liter of saline solution, the patient's condition was much improved, and after 7 hours consciousness returned. For the details of the examination of the blood and urine, which were made with great completeness, we must refer the reader to the original. The symptoms were similar to those following poisoning by nitrobenzol, yet they differed in some important respects.

Piperazin.—In addition to the testimony which continues to be added to that given last year, showing the inefficiency of this drug, a case is mentioned by Slaughter[1] in which, after the ingestion of 20 gr., the patient showed alarming symptoms of poisoning. There were cyanosis and semicoma; the pupils were minutely contracted; pulse and respiration slow and temperature slightly subnormal. Loss of motion was observed in both lower limbs; sensation was preserved. Recovery with free stimulation was complete, though slow.

Phosphorus-poisoning Treated with Potassium Permanganate.—Lanz[2] reports 12 cases treated by this method, which Antal[3] found efficacious in experiments on animals. The mortality in these cases was 5% higher than in 30 cases collected by v. Jaksch which were treated in the ordinary way. In 1 case which recovered after the ingestion of the heads of 10 packages of matches—the equivalent of 8 gr. of phosphorus—urobilin was found in the urine and feces, although it was absent from the urine in the first days. This agrees with the opinion of A. Riva, that urobilin and chromogen disappear from the urine and feces in severe phosphorus-poisoning, and that their reappearance indicates a good prognosis.

Phosphorism.—Magitot[4] gives this name to the symptom-complex resulting from phosphorus-poisoning at the state match-factories in France. All the workmen exposed to the fumes suffer without exception. The symptoms are partly common to all and in part special to those who are predisposed. The general symptoms are a cachectic condition, a subicteric color of the skin, a garlicky odor of the breath, the presence of phosphorus in the urine and saliva, wasting of the soft tissues, and the change in the chemic constitution of the bones. The special symptoms, depending on the predisposition of the individual, are chronic enteritis, with diarrhea, nephritis, cystitis, and bronchitis. Phosphorism is extremely persistent, continuing for a time after the exposure to the poison has ceased. This fact explains the tardy appearance of complications, and especially of necrosis. As long as the phenomena of phosphorism exist any operation for the removal of the necrosed bone will be followed by a return of the disease.

Potassium Permanganate in Opium-poisoning.—Sharp[5] summarizes the reports of the cases during the past year, and reaches conclusions very similar to those given in the *Year-Book* for 1896. If the permanganate is given immediately after the administration of the morphin, by the stomach or

[1] Med. News, Mar. 14, 1896.
[2] Berl. klin. Woch., Oct. 7, 1895.
[3] Ungar. Arch. f. intern. Med., i. 135, 1895.
[4] Therap. Gaz., Sept. 16, 1895.
[5] Ibid., Oct. 15, 1895.

hypodermically as a filtrate, it acts as an antidote. Improvement, especially in the respiration, was noted in animals experimented on, although the enormous doses of morphin necessary to destroy the lower animals made satisfactory experiments impossible, as the animals could not survive both drugs. The large majority of the cases reported are found by the author worthless, owing to a lack of care in the observations made during the treatment of the case. Callender's[1] case seems to be the only one reported in the abovementioned article where the permanganate was relied on, and where the evidence was strong that the patient's life was saved by its use.

Raw,[2] however, reports 3 cases of the successful treatment of opium-poisoning which offer striking evidence in favor of the use of potassium permanganate: Case 1.—M. G——, aged 27, had swallowed ʒij of laudanum. She was profoundly unconscious and evidently in the last stage of narcosis. Her stomach was at once washed out with a warm solution of Condy's fluid (ʒij to a pint of water) until the washings were quite colorless. She afterward was given ʒij of liquor potassii permanganatis every hour for 4 hours. Artificial respiration was kept up for 2 hours in addition. She made a good recovery. Case 2.—E. S——, aged 59, swallowed a large quantity of tinctura opii. She was comatose and could not be roused. The pupils were "pin-point," the respirations 6 a minute. Her stomach was at once washed out with a warm solution of Condy's fluid, and ʒij of liquor potassii permanganatis given every hour. In ¼ hour she showed improvement, and in an hour she was able to speak. She recovered. Case 3.—C. M——, aged 52, was admitted in a profoundly unconscious and comatose condition from opium and alcohol. Her stomach was at once washed out freely with Condy's fluid, and the effect was marvellous. In 10 minutes she was answering questions, and it was thought she had recovered; but she relapsed into a comatose condition, when potassium permanganate was given in ʒij doses every hour for 3 hours. The stomach was continually washed out with the solution until the washings were quite clear. This patient recovered.

Maynard[3] gives the results of the treatment of 19 cases by this method. His explanation of its mode of action seems rational. Moor advised the use of dilute sulphuric acid with the permanganate; this would substitute SO_4 for HO, on which the activity of morphin, according to Lauder Brunton, seems to depend. The permanganate oxidizes the morphin with which it comes in contact in the stomach, but not after absorption. The principal value of the method lies in the repeated washing out of the stomach, and in the fact that the decoloration of the solution (deoxidation) shows readily whether any opium remains to be removed. The mortality of the cases thus treated was 31.5%, as compared with 35% treated by other methods. The author states that this treatment was originally suggested by Dr. Barber Smith in 1884.

Pyoktanin-mercury is said by Dinkler[4] to have been used for the past

[1] N. Y. Med. Rec., vol. ii. p. 345.
[2] Brit. Med. Jour., July 13, 1895.
[3] Ibid., May 16, 1896.
[4] Pharm. Zeit., No. 89, 1896.

2 years in the government hospitals at Cairo and Port Said in chronic gonorrhea, favus, and gangrene with considerable success. Mixed with starch in equal parts, it is a cheap, unirritating, odorless substitute for iodoform. In gonorrhea a ½% watery solution was used; in favus, a ½% soap was applied twice a day and left to dry. Gauze is made as follows: 100 parts of ordinary gauze are saturated with a solution which contains 1 part of chlorid of mercury and 5 parts of chlorid of ammonium in 60 parts. Then this 1% dry bichlorid gauze is dipped in a ½% solution of pyoktanin and wrung out, which fixes the pyoktanin in the gauze. The deep-blue color is no drawback, but is said to be removable by washing.

Pyrantin, a new compound prepared by Prof. A. Piutti,[1] is described as a paraethoxylphenylsuccinimide, of the formula $(CH_2CO)_2.N.C_6H_4.OC_2H_5$. It is obtained by fusing either paraamidophenetol or phenacetin with succinic acid and extracting with boiling alcohol, when it is obtained in the form of colorless, prismatic needles, which melt at 155° C., soluble in 13.17 parts of water at 17° C. and in 83.6 parts of boiling water, insoluble in ether. Treated with hydrochloric acid or with melting potassium bisulphate, pyrantin is decomposed with succinic acid and paraphenetidin. Soluble pyrantin is the sodium salt of paraethoxylphenylsuccinamic acid. It is readily soluble in water and has the same physiologic action as pyrantin. Both preparations have been found to possess useful antipyretic properties. They lower the temperature of the body, it is claimed, 1° to 3° C., without affecting the blood, the heart, or the respiratory organs. Dr. Giovanni[2] recommends pyrantin, especially in fevers of a rheumatic nature, in daily doses of from 1 to 3 g.

The Action of Various Derivatives of Quinin on Infusoria.—Grethe[3] describes the results of a series of experiments on the paramecia. He found that the γ-phenylchinolin group was the most active agent, surpassing the action of quinin itself considerably. Phenylchinolin is derived from chinolin by the entrance of the phenyl group into its pyridin molecule. According to the place where this happens arise 3 isomeric bodies, called, α-, β-, and γ-phenylchinolin. The entrance of methyl gives γ-phenylchinolin; if to this be added methoxyl, OCH_3, or ethoxyl, OC_2H_5, there is formed γ-phenyl-p-methoxychinaldin or γ-phenyl-p-ethoxychinaldin; finally, there is γ-phenyltetrahydrochinolin; of these the γ-phenyl-p-methoxychinaldin is the most active, containing as it does the intensifying radicals methyl and methoxyl. All of this group, however, are far more active than quinin or any other of its derivatives; they are fatal instantly to the infusoria in strength of 1 : 1000. The author leaves the therapeutic application undecided, as the similarity of the paramecia to the malaria-parasite is too uncertain. Experiments, however, with these derivatives of quinin are very desirable. Tappeiner[4] continues the investigation of phenylchinolin on other of the lower organisms, and attains similar results, as shown by the following table:

[1] Am. Med.-Surg. Bull., Mar. 21, 1896, from Pharm. Zeit., xli. p. 71. [2] Ibid.
[3] Deutsch. Arch. f. klin. Med., Oct. 25, 1895. [4] Ibid., Dec. 13, 1895.

Paramecia killed by	1:1000.	1:5000.	1:10,000.	1:25,000.
(α) phenylchinolin . . .	1–2 minutes	8–10 minutes	10 minutes.	
(β) "	½ "	1–2 "	3 "	15–30 minutes.
(γ) "	1 "	2–3 "	3–4 "	4–6 hours.
Quinin	3–4 "	25–30 "	2 hours.	

Phosphin was examined in the same manner with results still more striking. The phosphin of commerce is a yellow coloring matter consisting essentially of amidophenylamidoacridin, $C_{19}H_{15}N_3$. Besides this, two new phosphins, methyl- and dimethylphosphin, were obtained from the dyeworks of Meister Lucius and Brüning at Höchst-a.-M. These three bases were used in the form of chlorids. The following table shows the results obtained:

Paramecia killed by	1:1000.	1:10,000.	1:25,000.	1:100,000.	1:200,000.	1:500,000.
Commercial phosphin .	Instantly	5 min.	20–25 min.	1¼ hours	1¾–2 hours.	
Methylphosphin . . .	"	1 "	7–9 "	¾–1¼ "	1¼–1½ "	1½–4½ hours.
Dimethylphosphin . .	"	1 "	7–8 "	¾–1 "	1¼–1½ "	2–4½ "

Thus the action of phosphin on infusoria is much stronger than that of mercuric chlorid on bacteria. The superiority of phosphin over phenylchinolin must depend on the fact that it is a higher condensed benzol combination, and not on the presence of the amido group, as Grethe's results with amido- and acetamido-γ-phenylchinolin were much weaker than with phenylchinolin. Other protozoa gave results almost precisely similar; among these the ameba of the class of rhizopods was especially interesting because of its apparent similarity to the plasmodium malariæ. These substances act much less forcibly on bacteria and fungi, as does, in fact, quinin.

These investigations may be of importance in the therapeutics of malaria, as Binz[1] has drawn attention to the importance of the study of the infusoria and their susceptibility to quinin in relation to the nature of malaria. In a later communication Tappeiner[2] gives the results of experiments on animals with γ-phenylchinaldin, which was made in the form of a hydrochlorate by the chemical manufactory at Höchst-a.-M. It is easily soluble in water, and has a sharp, burning taste like pepper. Locally, in concentrated solution, it is irritating, but less so than orexin, for example. After absorption it was only slightly poisonous to rabbits in proportion of 1 g. to 1 kilo of weight. Methyl and dimethylphosphins had a similar action, but were more poisonous. Subcutaneous doses of 0.1–0.15 g. per kilo, especially of the methylphosphin, caused in guinea-pigs tetanic spasms, which, however, in spite of their long continuance, did not cause death. On the normal as well as on the artificially raised temperature these substances had little effect. Celli at Rome tried phenylchinaldin in 12 cases of malaria with very little effect. V. Ziemmsen gave in 1 case doses of from 9 to 12 gr. repeatedly, which, although modifying

[1] Centralbl. f. d. Med. Wissen., 1867, S. 308. [2] Münch. med. Woch. Jan. 7, 1896.

the fever somewhat and twice aborting the paroxysms, did not control its course, and had to be followed by quinin.

Quinin-poisoning.—A remarkable case is reported by Roberts[1] from the ingestion of 6 dr. of the sulphate. The patient was found almost immediately afterward in a state of collapse; the temperature was 95° F.; respiration almost imperceptible, shallow, and slow; the pulse 45, thin and small. Recovery from this condition was unexpectedly rapid; in 24 hours there remained only a slight deafness, which disappeared within a week, and amaurosis, which lasted for 2 weeks; after months there still remained blurred vision for near objects, and dyschromatopsia, yellow and red being best seen. For the first week the retina was hazy and the edges of the papilla blurred; after that the usual pallor of the disk and contraction of the vessels came on, and remained with only slight improvement as long as the patient was under observation.

Salicylic Acid.—Vineberg, Schuchart, and Binz[2] assert that experimentation on animals and observation of cases show that salicylic acid and its salts act energetically as oxytocics and emmenagogues, thus providing another resource in scanty menstruation and amenorrhea, but, on the other hand, these drugs must be given with great caution to pregnant women.

Sodium Salicylate and Uric Acid.—Bohland[3] states that salicylate of sodium produces an increased excretion of uric acid only when there is an increased production of this body. According to Horbaczewski, uric acid is the metabolic product of nuclein, which latter is chiefly derived from the white blood-cells. The author's investigations with Hecken were carried out upon 2 healthy men. It was found that sodium salicylate considerably increased the excretion of uric acid, but that the number of leukocytes was also greatly increased. Thus, medium doses of salicylates produce a distinct increase in the white blood-cells, and, if Horbaczewski's theory is correct, a considerable leukolysis, and through this latter an augmented uric-acid excretion. According to the above experimental evidence, it is hardly to be expected that the salicylates should be of use in gout, and the author believes they should not be used, even as analgesics, either in gout or in the uric-acid diathesis. [The conclusions of this author are of interest, and especially so in view of the great reliance placed upon sodium salicylate in the treatment of lithemia by Haig.]

Sanoform is recommended as a substitute for iodoform. It was first produced by Gallinek[4] in 1895, by the action of iodin on oil of winter-green, and is said to contain $62\frac{7}{10}\%$ of iodin. It is a white powder, soluble in 10 parts of hot alcohol, very soluble in ether, also in vaselin; it melts at 110° and is odorless. Langaard states that the substance is nontoxic and apparently nonirritating. It is stable, not being affected by light or heat, which makes it possible to sterilize it, so giving it an advantage over iodoform. Experiments seem to show that sanoform has properties of desiccation, as it forms an ad-

[1] Therap. Gaz., Sept. 16, 1895, from the Indian Med. Gaz., Apr., 1895.
[2] Quart. Med. Jour., July, 1895, from Gaz. de Gynéc., Dec., 1894.
[3] Therap. Gaz., May 15, from Centralbl. f. innere Med., Jan. 18, 1896.
[4] Notes on New Remedies, June, 1896.

herent tissue with the secretion of wounds. Its chemic name is diiodomethyl salicylate.

Senega-root.—It has been noticed that a distinct odor of oil of wintergreen has been present in this drug, and it has been suspected that this was due to adulteration. Goldener[1] shows that under certain conditions many plants of the natural order Polygalaceæ afford methyl salicylate, and that the suspected adulterant is a natural constituent of the root. The Swiss Pharmacopœia has adopted the test for salicylic acid in the ether extract of senega-root to identify it as the true root.

Oil of sesamum has been subjected to thorough clinical examination, and the results indicate that it is a valuable article of food and a substitute for ol. morrhuæ. It is without odor and almost tasteless, and does not easily become rancid. Stüve[2] has observed its action in several hundred cases of phthisis and wasting diseases of all kinds and in all ages. He says that among these cases, which included many who could not tolerate cod-liver oil, there were very few, less than 10 in all, who suffered from eructations or nausea, or very rarely diarrhea, in which cases it had to be discontinued. The nutrition improved, especially in chronic colitis with constipation and increased production of mucus, when fat as an article of diet had been avoided and the nutrition had suffered in consequence, and the action on the bowels was noticeably good. In the emaciated sufferers with chronic gastritis, nervous dyspepsia, ulcer of the stomach, etc. 2 to 4 teaspoonfuls or more of the oil were given daily without any discomfort and with excellent results. The belief is said by v. Noorden to be an error that fat is badly borne in diseases of the stomach; it is necessary, however, that the form of fat should be chosen and administered with care. In many febrile conditions oil of sesamum was given with success; also in more than 200 poorly-nourished and cachectic children, with only 1 instance where it was not tolerated. Cod-liver oil is believed to be more readily absorbed than any other fat. Bucheim attributed this to the free fatty acids which it possessed, and lipanin has been recommended on this hypothesis, as it is composed of pure olive oil with the addition of 4–6% of oleic acid. Blumenfeld[3] has proved that the presence of a free acid does not aid the absorption of fat, and the author in a series of experiments shows that oil of sesamum, which contains no free acid, is readily absorbed in large quantities. It is well adapted for subcutaneous injection according to v. Leube's method, if that method should come into general use.[4] It is not absorbed from the rectum, nearly the entire quantity having been rejected after 12–24 hours' retention in the bowel. An important advantage of the oil of sesamum is its cheapness, but a good quality is very essential. There are said to be numerous brands in the market, and the quality has in general improved, owing to its increased use in commerce.

Metallic Silver and Silver Lactate and Citrate.—Credé[5] gives

[1] Squibb's Eph., Jan., 1896.
[2] Berl. klin Woch., Mar. 16, 1896.
[3] Zeit. f. klin. Med., xxviii., 1895.

[5] N. Y. Med. Jour., Apr. 25, 1896, from Deutsch. med. Zeit., Mar. 26, 1896.

the results of his investigations of silver and some of its salts as antiseptics. He has satisfied himself metallic silver when brought into contact with colonies of schizomycetes kills them, without exerting any action on the animal tissues. So it may be remarked that the late Dr. Marion Sims's choice of silver wire as a material for sutures was a happier one than could be realized at the time. Credé says that aseptic wounds coated with silver-foil remain aseptic for weeks, and heal better than with any other dressing. Instead of silver-foil, he has lately employed a dressing material made by Max Arnold of Chemnitz, in the fabric of which metallic silver is intimately blended in such a manner as to admit of its being cut or torn into any shape desired. There is also a dressing in the form of a mull containing powdered silver that may with advantage be substituted for iodoform-gauze in packing deep wounds. Numerous experiments have shown that silver forms a lactate with the lactic acid produced in the metabolism of the microorganisms, and this compound kills them; therefore it occurred to Credé to make direct use of silver lactate instead of silver in the metallic state. This preparation, known by the trade name of actol or aktol, he thinks fulfils all the requirements of an antiseptic better than any other. He has given as much as 15 gr. of it subcutaneously without the least bad effect; there was only a slight burning pain at the site of injection, lasting a few minutes. Silver lactate forms no insoluble compounds with the alkaline secretion of a wound or with tissue-juices, as, for example, mercuric chlorid does, but only soluble ones, which gradually permeate the tissues and thus extend their action to some distance from the surface. Silver citrate, however, seems to be quite as efficient, and to be free from some minor disadvantages, which are not specified, of the lactate. The citrate has the trade name of itrol. Credé says it is a perfectly harmless antiseptic and an excellent dusting powder for wounds. In the course of 4 months he has treated many hundreds of wounds with it, with not the least untoward effect. From another source [1] we learn that the lactate or actol is irritating to mucous membranes, and is easily decomposed by the action of light. Itrol is said to be free from these disadvantages, yet has the same marked antiseptic properties.

The Direct Influence of Sodium Bicarbonate on the Gastric Secretion.—In view of the uncertain teaching as to the effects produced on the gastric mucous membrane by the alkalies, Reichmann [2] made a series of experiments which may be summarized: Patients drank before breakfast, during successive mornings, alternately 200 c.cm. of a bicarbonate solution. After 15 to 30 minutes the gastric contents were aspirated, but neither small nor large doses appeared to influence the quantity of fluid secreted. The same experiment was tried in subjects who, however, were allowed shortly after drinking to eat a breakfast. Here, again, the results of aspiration were negative. In the next place, the alkali was administered every morning during several weeks, but no appreciable effect was produced. On the other hand,

[1] Notes on New Remedies, June, 1896.

[2] Therap. Monatsh., Mar., 1894; Brit. Med. Jour., July 6, 1895.

when taken after food the acidity of the gastric contents was diminished in proportion to the amount of bicarbonate taken. Again, this mode of investigation when continued over several weeks produced no effect on the gastric secretion. In conclusion, the author states that the examinations numbered 103; that the drug will act as an alkali even to a considerable degree, but that it in no way influences the secretory power of the stomach. Nevertheless, he admits the value of a drug which is capable of lessening acidity, and he states that the long-continued use of weak alkalies will no doubt produce a tonic effect on a weak gastric mucous membrane. [These experiments are certainly of interest, and, if confirmed, will compel us to alter our long-held views of the efficacy of alkalies as peptic stimulants when given to the fasting.]

Solanum Paniculatum.[1]—The root of this plant is said to be used in Brazil, where it grows, as a purgative; also in diseases of the liver and spleen as an alterative, tonic, and drastic. Kobert, who experimented with it, found it inert, while Michaelis thinks it is a stomachic and useful in biliary colic and in chronic dyspepsia. He gives 15 drops of a fluid extract 3 times a day.

Somatose as a Galactagogue.—Drews[2] gives a number of cases in which the use of this agent, in which the albuminoids and nutritive constituents of flesh are converted into soluble albumoses, 5 parts of somatose representing 30 parts of beef in nutritive value, was of value to increase the secretion of milk. He asserts that in all cases in which an abundant secretion of milk does not take place, or in which it shows a tendency to cease too early, somatose should be employed before giving the child over to the dangers of artificial feeding. The proper dose for this purpose is a teaspoonful 3 or 4 times a day in warm milk, cocoa, or soup. On account of the almost complete absence of taste somatose is nearly always well borne even for long periods.

Stearates of the Alkaloids.—This combination has been recommended by Zanardi[3] to facilitate the solution of alkaloids in the fats and oils, to increase their efficacy when applied externally or in the form of suppositories.

1. *Morphin stearate*, $C_{17}H_{19}NO_{31}.C_{17}H_{35}COOH$, is obtained either by the direct action of stearic acid upon morphin or by double decomposition. To prepare it by the first method molecular proportions of stearic acid (5.08) and morphin (5.72) are taken. The stearic acid is slowly heated in a glass retort with 100 c.c. of absolute alcohol until dissolved, the morphin being then added in small portions. The warm solution is filtered, and on cooling will deposit morphin stearate. The mother-liquor, if evaporated, will deposit more crystals. If an absolutely neutral morphin stearate is desired, double decomposition between sodium stearate and morphin hydrochlorate must be resorted to. The sodium stearate is first prepared by heating 20 c.c. of normal soda solution (0.8 sodium hydrate) and 5.68 g. of stearic acid together with 50 g. of distilled water. To the solution thus obtained a solution of 7.51 g. of morphin hydrochlorate in 100 g. of water is added. The mixture is stirred, and the morphin

[1] Med. Chir. Centralb., Apr. 24, 1896.

[2] N. Y. Med. Jour., June 27, 1896, from Centralbl. f. innere Med., June 6, 1896.

[3] Am. Med.-Surg. Jour., May 16, 1896, from Boll. Chir.-farm., 1896, No. 4.

stearate deposits in the form of a white, voluminous precipitate. The latter is thrown on a filter and washed with water until the washings are no longer rendered turbid by hydrochloric acid, or, after the addition of nitric acid, by silver nitrate. This purified stearate is then dried and crystallized from alcohol. Morphin stearate thus obtained occurs in the form of white, crystalline, brilliant scales of a greasy touch. It melts at 84° to 86° C., decomposing at 100° C., and chars at 150° C. It is almost insoluble in water, soluble in ether and in cold alcohol, and very freely so in hot alcohol; sparingly soluble in petroleum, ether, benzin, chloroform, or oil of turpentine. At ordinary temperatures it dissolves in oils in the proportion of 1 : 100, and is also soluble in fats and in vaselin. The presence of stearic acid in morphin stearate is detected by cupric sulphate, while morphin is shown by nitric acid or the other known reagents for it. Morphin stearate contains 50.17% of morphin, and is employed in preparing morphinated oils, ointments, and suppositories.

2. *Atropin stearate*, $C_{17}H_{23}NO_3.C_{17}H_{35}COOH$, is obtained by the same processes as morphin stearate. It crystallizes in fine white, brilliant needles, greasy to the touch, melting at 120° C., and beginning to decompose at 170° C. It behaves toward solvents just like morphin stearate. It contains 50.43% of atropin. Stearic acid is detected by floating the stearate on water and treating with a solution of cupric sulphate; atropin, by first dissolving it out by the aid of tartaric acid and applying the usual reagents. The 1 : 500 solution of stearate of atropin in almond oil is considered an excellent substitute for oil of hyoscyamus or oil of belladonna. The stearate is dissolved in the oil with the aid of gentle heat. Extract of belladonna may be advantageously replaced in ointments and suppositories by atropin stearate.

3. *Cocain stearate* is prepared in the same way as the foregoing stearates. Take 3.03 g. of cocain and 2.84 g. of stearic acid. Its formula is $C_{17}H_{21}NO_4.C_{17}H_{35}COOH$. It crystallizes in white, brilliant needles, joined in bundles. It melts at about 90° C., and contains 51.63% of cocain. Toward solvents it behaves similarly to the foregoing stearates. Stearic acid is detected as before, while the cocain is shown by first treating with tartaric acid to liberate it from its combination, and then applying the usual reagents.

Stypticin as a Hemostatic.—Gottschalk[1] has used this new hemostatic, which is obtained by the oxidation of narcotin, in 47 cases of uterine hemorrhage. It may be given hypodermically or by the mouth in doses of ¾ gr., repeated 5 or 6 times a day. It is said to have a local and general sedative action, and for this reason to be preferable to hydrastis in dysmenorrhea. The author claims that stypticin promptly checks hemorrhage due to uterine subinvolution. In fungous endometritis it is useful after curettage, and in hemorrhage due to fibroids or the climacteric. In congestive menorrhagia it may be combined with hydrastin. It is said to stimulate uterine contraction, therefore would be contraindicated in threatened abortions. It has little influence on the bleeding of uterine polypi. In profuse menstruation the remedy is best given 5 times daily for 4 days before the expected period.

[1] Am. Med.-Surg. Bull., Feb. 29, 1896, from Brit. Med. Jour., No. 1828, p. 7.

Sulfonal.—Andrews[1] states that this drug has a valuable antispasmodic action. He has used it in painful muscular spasm after fractures of the thigh, and finds that its action is more sedative than the opiates. Some cases of persistent hiccough are stopped by it; it has also been used with good effect in the treatment of nocturnal emission of semen. Shaw-Mackenzie[2] recommends it as a very useful remedy in railway-sickness and sea-sickness. After numerous observations he concludes that antipyrin, phenacetin, the bromids, and chloral do not give as good results in this class of cases as sulfonal. The dose need not exceed 10 or 15 gr., and no depression or other ill effects are noted.

Influence of Certain Groupings on the Physiologic Action of Synthetic Remedies.—In an interesting paper read at the last annual meeting of the Maryland Pharmaceutical Association, Coblentz[3] says: "There is but little doubt that a relationship between chemical constitution and medicinal action exists to a certain extent. This is evidently subject to certain conditions. Most important among these may be mentioned the intramolecular structural arrangement; the degree of solubility which regulates the more rapid or slower absorption in the system; various decompositions which these bodies undergo after entering the body; and the electrolytic conductivity of the compound." As an illustration of the last-mentioned condition the relation between the salts of potassium, sodium, and rubidium is given. "The electrolytic conductivity of the iodids of these metals shows an ascending progression similar to that of the molecular weights. Thus—Dilution 32:

Element.	*Na.*	*K.*	*Rb.*
Molecular weight	23	39	85.4
Elect. cond. of iodids	105.7	128.5	130.6

These data are said by Erdmann not only to represent the actual and relative rapidity with which the iodids are distributed throughout the organism under the influence of osmotic pressure and electric currents, but the data also afford a measure of their degree of medicinal activity, for physiologic activity is conditioned by the ability to enter into chemic reactions, and, according to Ostwalt's law, chemic activity is proportional to the electrolytic conductivity. This explains why the practitioner prefers potassium iodid to the sodium salt, although the latter contains 85% iodin compared to 76% of the former; also, upon these grounds, rubidium iodid, containing about 60% iodin, is receiving attention, as it is claimed to be far more active than either of the other iodids."

The alkaloids, hypnotics, and antipyretics are considered as to their composition and action. It would be beyond the limits of this department to quote more fully, but a knowledge of the chemistry of these synthetic products, which are being manufactured in such quantities, seems an important complement to their clinical observation. Boyer[4] discusses this subject at some length, calling attention to the extensive and rapid development of the manufacture of synthetic remedies. He says: "A medical man can almost foresee the probable value of new compounds if he will but view them from a

[2] Ibid.
[3] Druggists' Circ. and Chem. Gaz., June, 1896.
[4] Therap. Gaz., July 15, 1895.

chemical-medical standpoint." [This statement may be varied slightly in saying that their dangers may also be foreseen, which would be a still more important gain, judging from the numerous instances of the careless use of these new remedies with which current medical literature abounds.]

Taka Diastase.—Lascar,[1] in a paper discussing the subject of the digestion of starches, describes this extract of malt, the discovery of Mr. Takamine, a Japanese chemist. It is a dry powder, capable of converting more than 100 times its weight of starch into a soluble state, the process being completed in 4 minutes. The author states that with the best malt-extract between 7 and 8 minutes were required to convert its own weight of starch into a soluble form. Taka diastase is tasteless and odorless, and can be given in very small bulk. The dose is from 1 to 5 gr.

Tannalbin.—Gottlieb[2] and Engel[3] report their observations on a new preparation of tannin. The former describes tannalbin as a slightly yellowish, tasteless powder containing 50% of tannin, made by subjecting a compound of tannin and albumin to a heat of from 212° to 248° F. for 5 or 6 hours, whereby it acquires the property of resisting gastric digestion, while it still remains susceptible to the slow action of the intestinal juices. Von Engel has tried it in 40 cases. He reports that he has observed no harm from its use. The dose for adults is 15 gr., that for children half that amount, from 2 to 4 times a day. He found it serviceable in all diarrheal affections in which an astringent is indicated, especially chronic intestinal catarrh. It proved efficient in 25 out of 29 subacute or chronic cases, and in 9 out of 10 acute ones. Vierordt[4] substantiates the claims made for this drug in acute and chronic diarrhea. It is given to adults in doses of 8 to 15 gr. 4 times daily.

Tannigen has been used by Munger[5] in cases of hypertrophic rhinitis and chronic nasal pharyngitis. It may be used as an alcoholic solution in the strength of a dram to the ounce. The pure drug proved too strong; sometimes the solution was made weaker than this, but it did not prove as satisfactory in its results as was hoped, and seemed to act as a stimulant rather than as an astringent.

Theobromin Salicylate.—The shortcomings of diuretin are such as to lessen its usefulness—its instability in the atmosphere—since the carbon-dioxid withdraws a portion of the theobromin from its salicylic-acid combination; its alkaline reaction; and its sweetish taste. Theobromin salicylate is said[6] to be free from these drawbacks. It is a definite chemical salt of the formula $C_7H_8N_4O_2COOC_6HOH$, occurring as small white needles, acid in reaction, of an agreeable bitter taste, and but slightly soluble in water. The dose and the uses of this salt are the same as those of diuretin.

Traumaticin is not new by any means, and it has already had an extended use for certain purposes. It is therefore instructive to learn of the most advan-

[1] Therap. Gaz., July 15, 1895.

[4] Deutsch. med. Woch., 1896, No. 25. [5] Am. Med.-Surg. Bull., May 16, 1896.
[6] Ibid., Mar. 7, 1896, from Bericht über das Jahr 1895.

tageous method of preparing it.[1] Traumaticin is a saturated solution of gutta-percha in chloroform; it is best prepared as follows: The lightest-colored gutta-percha procurable is cut into small pieces and macerated with 12 or 15 times its weight of pure chloroform for 24 hours, with frequent agitation. The mixture is then transferred to a retort and about $\frac{2}{3}$ of the chloroform distilled off over a water-bath. The traumaticin thus obtained is a thick, homogeneous liquid, to which the requisite medicament may be added.

Trional.—Berger[2] reports a case of acute poisoning after the ingestion of 1 dram daily for 3 days. The patient was ataxic before the administration of the trional, and had also the opium-habit, for which he was being treated. The ataxia increased; delirium, difficulty in speaking, and at times Cheyne-Stokes respiration were present. The urine was red, but clear, containing no albumin or sugar. The blood was unchanged. The somnolence lasted 4 days, the other nervous symptoms 4 days more. The urine remained wine-colored for more than 2 weeks. [The author's opinion as to dosage corresponds with those given in the *Year-Book* for 1896, p. 1060.] Reinicke[3] states that 3 cases of poisoning have been reported, 2 of which ended fatally. In a fourth case, in which the drug was given in moderate doses, 15 gr. every second day, there occurred nausea, diarrhea, and cardiac weakness; the urine contained albumin and casts, with a few blood-cells. The patient recovered gradually, but was left in a weak and anemic condition. The writer says it remains to be seen whether, even when trional is used with the utmost caution, there is security from ill effects, and that in this respect it does not differ from others of the newer hypnotics.

Treatment of Renal Deposits of Uric Acid.—Klemperer[4] in a review of this subject says that a solution of the calculus by medical means is not to be hoped for; the treatment of calculi is therefore surgical. The prophylaxis, however, is of even greater importance. Precipitates are formed when the solution is too concentrated; this is to be avoided by drinking a large quantity of water, and at the same time diminishing as much as possible its excretion by other channels. The author says, further: We know that the uric acid is not an insufficiently oxidized urea, but that it comes directly from the phosphorus-holding albumin, the nuclein; the diet must then be so arranged as to diminish the albumin-containing nuclein without reducing other albumins. Milk, egg-albumen, and vegetable albumen are desirable, while meat is to be avoided. The thymus-gland contains the most nuclein; then follow the liver, kidney, brain. In this question individual differences are often important. "The less nucleoproteid taken, the less uric acid produced," may be true for all, but "the more nucleoproteid, the more uric acid," is not necessarily true, as in some cases the nucleoproteid may be converted to urea. Coffee and its related products are said to produce uric acid. Over-exertion may have the same effect. Among numerous more or less efficient drugs

[1] Squibb's Eph., 1896, from Pharm. Jour. and Trans., vol. xxv. p. 1024.

[4] Münch. med. Woch., June 30, 1896.

which influence the reaction of the urine and its uric-acid content, the author mentions as most useful urea, which, according to Rüdel,[1] dissolves uric acid and increases diuresis. It may be given in daily doses of 5 dr.

Uricedin.—Meisels[2] finds that uricedin, which has great similarity to Cantani's powder and consists of sodium citrate, sodium chlorid, and lithium citrate, is inefficient to dissolve uric acid or to prevent its precipitation in the tissues. [This is less favorable than Langstein's report of last year (*Year-Book* for 1896, p. 1075), but a brief life has been the lot of all the vaunted solvents of uric acid thus far; in fact, the treatment of the uric-acid diathesis is on a basis no more rational than it was last year. Piperazin has ceased to find favor; nothing concerning lysidin (see *Year-Book* for 1896, p. 1047) has been reported this year. The theory of Horbaczewski is opposed by Ritter,[3] although assumed by Klemperer and Bohland (vide supra) in their discussions of the subject. The present state of uncertainty in which we rest with regard to the function and fate of the nucleins makes a solution of the question impossible for the moment.]

Urotropin, or **hexamethylenetetramin,** is recommended by Nicolaier[4] as a diuretic and solvent for uric-acid concretions. During its use the urine remains acid; even in 2 cases of cystitis, with strongly ammoniacal urine, the fermentation in the bladder ceased with doses of from 8 to 24 gr. daily. Urotropin seems to be absorbed unchanged. The author has detected it in the urine by means of bromin-water, with which it forms an orange-yellow precipitate of urotropin dibromid 15 minutes after administration. A single dose of 8 gr. required 13 hours for elimination, a dose of 16 gr. 27 hours. The drug may be given in 30-gr. doses daily without discomfort; 90 gr. a day, continued for some time, have caused slight symptoms of vesical and renal irritation.

Valerianate of amyl is said to give good results in cases of bilious colic,[5] not only as a sedative, but by aiding in the expulsion of the calculus. It does not act so well in nephritic colic. The dose is 2 or 3 gr. in capsule 2 or 3 times a day.

ANATOMY.

By C. A. HAMANN, M. D.,

OF CLEVELAND, OHIO.

Anatomic Nomenclature.—At its meeting in May, 1895, the German Association of Anatomists adopted the nomenclature proposed by a committee of that society. This committee, consisting of several of the most distinguished German anatomists, aided at various times by anatomists of other nations, after years of labor have suggested a nomenclature which it is hoped will be universally used.

Descriptive and topographic anatomy were alone considered, no changes having been made in the terms applied to the minute structures. Only the Latin names were determined, it being left to the different nations to translate the terms into their own languages.

The following general principles have been adhered to: Each part is to have but a single name, which is to be in Latin and is to be philologically and orthographically correct. The names are to be as short and simple as possible, and shall not attempt to describe or "interpret" organs.

Compound names are to be formed with as much uniformity as possible, though some very firmly-rooted names, as sternocleidomastoid, are allowed to remain unchanged. Some of the personal names applied to organs and parts have been retained, others abolished; in the future further changes may perhaps be made in these names. Names which have been applied to various parts in recent years in the domain of the specialties are to be largely retained, for it is deemed wise that the student should learn those terms in his early years of medical study which he will subsequently find in use when he reaches the clinical and practical portion of his medical course.

Terms lacking in clearness and those used in different senses by different writers have been eliminated and new ones applied. As examples may be given the following names, used in the description of the lung (pulmo-): *Basis pulmonis, apex pulmonis, sulcus subclavius, facies costalis, facies mediastinalis, facies diaphragmatica, margo anterior, rami bronchiales, ductuli alveolares, etc.*

As names of some of the branches of the nervus medianus the following are given: *Ramus palmaris n. mediani; ramus anastomoticus cum n. ulnari; nn. digitales volares communes.*

Some terms used in topographic anatomy: *Regiones colli, regio colli anterior, regio submentalis, hyoidea, laryngea, fossa jugularis, etc.; trigonum omoclaviculare, regio nuchæ, etc.*

V. Bardeleben,[1] from whose article the above facts are mostly taken, expresses the hope that the new nomenclature, which has required much labor, time, and money in its preparation, will be used in the future, not only by anatomists, investigators, and teachers of the various nations, but also by physiologists, pathologists, and by the practising physicians; thus only will the protracted and difficult work of the committee of revision be of value.

The new nomenclature is being introduced in the extensive "Handbuch der Anatomie des Menschen," edited by Karl v. Bardeleben. The atlases of Toldt and Spalteholtz also employ the new terms, and the Berlin Laryngological Society has recently adopted it.

Prof. His[2] gives a full list of the new terms.

Röntgen Rays.—As the Röntgen photography is yet in its infancy, it is difficult to state what advantages will accrue to anatomy from its use; further changes and improvements will doubtless promote and extend anatomic research. In the study of the osseous structures and of the topographic anatomy of the skeleton it will probably prove to be useful. Salvioni[3] and others have published articles showing, among other things, the relations of the carpal bones, etc. Chapin and Morton[4] publish a skiagraph of a marasmic infant, showing particularly the osseous structures and the extent to which ossification had advanced. A modification of the Röntgen process by means of an apparatus called the "photofluoroscope" has been devised by Bleyer[5] and may perhaps be of use in anatomical studies. Braus[6] has made photographs of the arteries of the hand which had been injected with mercury. He gives the technic of the method. The Röntgen rays can also be made use of in the study of the lymphatics.[7]

OSTEOLOGY.

Obliquity of the Forearm.—Potter[8] has investigated the degree of obliquity of the forearm to the arm in the male and female. In 90 females the angle of obliquity was found to be 167.35°; in 95 males the angle was 173.17°. Thus the forearm is shown to be markedly more oblique in the female than in the male. Potter further shows "that there is no deviation inward of the forearm during flexion in the upper extremity of either sex." [This may perhaps be of interest surgically, as after certain fractures about the elbow the angle of obliquity is often changed, and the carrying function of the arm, as it has been called by Allis, is interfered with; the normal differences in the two sexes should then be considered in estimating the amount of deformity.]

[7] Wien. klin. Woch., No. 4, 1896.

[8] Jour. Anat., and Phys., vol. xxix. p. 488.

Linea Quadrati of Femur.—Brockway[1] has examined 900 femora, and did not find a distinctly marked linea quadrati in any of them.

Supracondyloid Process of Humerus.—Tandler[2] describes a hitherto unrecorded variation of this process. The pronator radii teres arose by two heads from the humerus, and the upper one, which had its origin from the position at which one would expect to find the supracondyloid process, had in it an ossicle, $\frac{3}{4}$ cm. long and $\frac{1}{2}$ cm. wide, imbedded in fibrous tissue.

BLOOD-VESSELS.

Structure of the Arterial Wall.—Bonnet[3] objects to the customary and time-honored division of the coats of arteries into three layers. Of the six layers which Henle first described, he says that the so-called elastica interna, or fenestrated membrane of Henle, and the elastica externa are to be regarded as boundary-plates (grenzlamellen) of the media; they really belong to the media, therefore. He describes the arterial wall as consisting of—1. An intima, comprising only the endothelium; 2. Media, comprising the elastica interna and elastica externa, together with the entire system of elastic and muscular fibers between these two. If there is present, as is the case in the largest arteries, a layer of longitudinal fibers (gestreiftelager of Kölliker), it is to be regarded as part of the media; 3. The adventitia or externa, which would comprise everything external to the elastica externa. Such a mode of division, he states, is favored by histologic and embryologic facts.

Communications between Large Arteries and Veins.—Gerard[4] has found direct communications between large arterial and venous trunks; the communicating branches are from 0.4 to 2 mm. in diameter; they were seen relatively often in new-born infants between the external iliac artery and vein and popliteal artery and vein. He regards these channels as atavistic in origin. Histologically, they resemble veins more than arteries; muscular and elastic fibers are few in number. [It is possible that these so-called anastomosing branches between arteries and veins are in reality vasa vasorum.]

Hepburn[5] describes a rare case of a **third coronary artery of the heart**; all 3 vessels arose independently from the aorta. They were all of about the same diameter; 2 arose from the anterior sinus of Valsalva, and the third from the left posterior sinus. The supernumerary artery supplemented the left coronary, which was defective in its mode of distribution.

LYMPHATICS.

Lymphatics of the Anus and Rectum.—Gerota[6] has studied the lymphatics of the anus and rectum in young children. His results, besides agreeing with facts previously known, show that there are glands, called by him anorectal, lying on the outside of the muscular coat on the posterior part of the rectum, following the course of the inferior hemorrhoidal artery. The

[6] Arch. f. Anat. u. Entwickelungsgesch., 1895.

cutaneous lymphatics and those of the mucosa communicate freely. On the columns of Morgagni the lymphatic vessels are very numerous; not so in the grooves between them. The cutaneous lymphatics empty, as a rule, into the inner and upper group of inguinal glands.

Lymphatics of the Umbilical Region and Bladder.—Gerota[1] finds that the deep lymphatics of the umbilical region accompany the deep epigastric artery, passing through several small lymph-glands in their course; these glands are called lymphoglandulæ epigastricæ inferiores; from these the lymph passes to the deep inguinal glands. In 2 cases he was able to demonstrate the presence of a small gland behind the umbilicus in the subperitoneal tissue. There are also lymphatics accompanying the round ligament of the liver. The author calls attention to the possibility that these lymph-channels have an etiologic relation to some of the cases of suppuration in the subumbilical space described by Fischer.[2] Concerning the lymphatics of the bladder, he confirms the statements of previous authors that there are 2 sets of lymphatic vessels in the bladder-wall—1 in the mucosa, the other in the muscular coat. Those of the mucosa, which are most abundant in the trigone, and here communicate with the urethral lymphatics, empty into the glands on the lateral wall of the pelvis. Those of the muscular coat pass through glands which lie in the fatty tissue near the umbilical arteries; these glands he calls lymphoglandulæ vesicales laterales. He also found glands in the prevesical space (lymphoglandulæ vesicales anteriores). Both these last-named sets of glands probably play a not unimportant role in suppurative and neoplastic processes in the space of Retzius. The lymph passes from the last-named 2 sets of glands into glands on the *lateral wall* of the pelvis.

Lymphatics of the Lung.—Miller[3] describes the pulmonary lymphatics as consisting of 4 sets: 1. Those associated with the bronchi; 2. Those associated with the arteries; 3. Those associated with the veins; 4. Those of the pleura. Some of the results of his investigations are the following: In the bronchi there is a network of lymphatics lying external to the network of blood-vessels; the vessels end in the terminal bronchi in 3 small vessels. No lymphatics are found in the atria and air-sacs. He has never seen stomata on the surface of the bronchial mucous membrane, nor lymph-capillaries between the epithelial cells of the bronchial mucosa. From the terminal bronchi 1 of the lymph-vessels accompanies a branch of the pulmonary artery. The larger arteries are accompanied by 2 lymphatics which intercommunicate; the smaller arteries have a single accompanying lymph-vessel; the same is true in regard to the veins. Concerning the pleural lymphatics, he states that they form in the hilus of the lung from 3 to 5 large trunks, which anastomose at the hilus with the pulmonary lymphatics. He denies the presence of stomata between the endothelial cells of the pleura.

Regeneration of Lymphatic Vessels.—Bayer[4] calls attention to the edema of the external genitalia which is sometimes observed after bilateral ex-

[1] Anat. Anz., Bd xii. p. 89.
[2] Samml. klin. Vortr., Leipzig, 1894.
[3] Anat. Anz., Bd xii. p. 110.
[4] Arch. f. klin. Chir., Bd xlix. p. 637.

tirpation of the inguinal glands. He refers to the fatty tissue which surrounds lymph-glands, and discusses its importance in the restoration of the lymph-channels after the removal of glands. If there has been for some time interference with the flow of lymph through diseased glands, there can be seen in the periglandular fatty tissue numerous spaces and channels; the smaller channels unite and form larger ones, and finally lymphatic vessels are formed, which accompany the blood-vessels as perivascular spaces. The more marked the interference with the lymph-circulation, the more extensively are perivascular channels established. There is also a secondary dilatation of the normal lymph-channels of the lymph-glands. He also shows that the periglandular fatty tissue by an increased activity of its cells becomes converted into lymphoid tissue under favorable circumstances—*i. e.* if there has been healing by first intention and if the reparative processes have not been interfered with by erysipelas, sloughing, or other inflammatory processes. The preformed spaces in the periglandular connective and adipose tissues thus act as collaterals when there is interference with the normal flow of lymph; and this fact, together with the formation of lymphoid from fatty tissue, leads Bayer to regard the periglandular adipose tissue as a part of the lymphatic system. The practical deductions that he draws from his work are that the fatty tissue surrounding lymph-glands should be as little disturbed as possible in the removal of the glands, and that union by first intention with the avoidance of inflammatory complications should be sought for.

DIGESTIVE SYSTEM.

Peritoneal Fossæ.—Waldeyer[1] calls attention to a fossa which may be found between the liver, duodenum, and upper end of the right kidney if the hepatorenal ligament is strongly developed. The fossa lies under this ligament, between the kidney and duodenum; in the case he describes the fossa was large enough to lodge the terminal phalanx of the thumb. He furthermore calls attention to the occasional large size which the plicæ umbilicales laterales may reach; the umbilical arteries, or their remains in the adult, may have a mesentery 4 or 5 in. in width just above the bladder, and upon making the abdominal walls tense the median inguinal fossæ will appear as quite deep pockets. These abnormally developed peritoneal folds may possibly give rise to internal strangulation.

Fawcett[2] has made the observation that the presence or absence of the cecal or ileocecal pouches is accompanied by absence or presence of the duodenojejunal pouch; in other words, when the cecal fossæ are present the duodenojejunal pouch is absent, and vice versa. No cause for this seeming correlation is apparent.

Extent of the Great Omentum.—Eccles[3] found in 37 out of 89 cases that the great omentum completely covered the small intestine. Its length from the transverse colon to the free border varied between 7.5 and 33.5 cm.

[1] Deutsch. med. Woch., No. 46, 1895, p. 190. [2] Jour. Anat. and Phys., vol. xxix., 1895.
[3] St. Barth. Hosp. Rep., vol. xxx.

The celiac plexus furnishes the nerves to its vessels. Among its functions are the protection of the intestine, absorption of fluids, and also the filling up of spaces between coils of intestine.

Development of the Pancreas.—Jankelowitz[1] has shown by the study of the human embryo of 4 weeks that the pancreas arises from 3 separate "anlagen," 1 dorsally from the epithelium of the duodenum, and 2 ventrically from the ductus choledochus. The development is thus seen to be the same as in the lower animals that have been studied.

Crescents of Gianuzzi.—Küchenmeister[2] has examined the salivary glands of 2 healthy persons shortly after death; he believes that the crescents of Gianuzzi or demilunes of Heidenhain are *not* mucous but serous in character.

Form of Spleen.—Cunningham[3] has investigated the form of the spleen and kidneys by hardening these organs in situ and by reconstruction methods; his description differs somewhat from that given by His. He describes the spleen as having the "shape of an irregular tetrahedron, with its apex above and its base below." The apex is directed inward and upward. The three surfaces, gastric, renal, and basal, which look toward the abdominal cavity, meet at a blunt prominence, which Cunningham calls the "internal basal angle;" these surfaces are separated from one another by ridges. The basal surface of the spleen is in relation with the tail of the pancreas, and to a varying extent with the colon.

NERVOUS SYSTEM.

Neuroglia.—Weigert[4] has studied the neuroglia for the past 7 years. Up to the time of his publication the difficulty in studying the neuroglia consisted in a lack of satisfactory methods of staining this tissue. The method which he has devised does not enable the observer to trace the earliest stages of neurogliar development; only certain peculiarly differentiated fibers are shown. In the human embryo the neuroglia consists only of cells and their processes; in the adult it is composed of cells and fibers, the latter greatly predominating, so that they are to be regarded as the chief constituents. The fibers are not to be looked upon as processes of the cells; they are not identical chemically with the processes of the glia-cells. These fibers, which he stains by his own method, are to be regarded as intercellular substance, not nervous in structure; they are, however, different from the fibers of ordinary connective tissue. Weigert states that, morphologically, the neuroglia is to be regarded as a connective tissue, though the question of its histogenesis will have to be decided by embryologists. In the second part of the work there is given a very accurate account of the topography of the neuroglia, the relations of this substance in all the important parts of the nervous system being

[1] Arch. f. Mikr. Anat., vol. xlvi. 4, 1896. [2] Ibid.
[3] Jour. Anat. and Phys., vol. xxix.
[4] Festschr. z. 50 Jährigen Jubiläum des Arztl. Ver. zu Frankfurt-a-M., Apr., 1895.

described. At the end of the work is given an account of his methods of staining.

Pyramids of the Medulla.—Dejerine and Thomas[1] have demonstrated that the pyramids of the medulla in man contain, in addition to the direct and crossed pyramidal fibers, other fibers, called by them homolateral pyramidal fibers. These, after leaving the pyramid, take their course outward and backward through the gray substance, cutting off the anterior horn, and thus enter the lateral column of the same side. In 1 case they were traced as far as the 4th sacral root. These investigators have traced the crossed pyramidal tract (in cases of degeneration from disease) to the level of the 3d and 4th sacral nerves, in 1 case even to the beginning of the filum terminale. They have followed the direct pyramidal tract to the level of the first lumbar nerve.

Motor Nerves of Muscles of Eyeball.—Mahaim[2] has determined experimentally, by removal of the motor nerves of the eye-muscles in rabbits, according to Gudden's method, that there are in the lateral portion of the posterior longitudinal bundle fibers which connect the nuclei of the 3d, 4th, and 6th cranial nerves.

Trifacial Nerve.—Zander[3] found that the areas supplied by the sensory branches of the trifacial nerve overlap; in fact, some of the branches of the infraorbital, mental, supratrochlear, and other nerves were traced 1 cm. beyond the median line.

Relations between the State of Nerve-cells and Psychical Phenomena.—Cajal[4] discusses the question as to whether more than one nerve-cell is concerned in a given sensation, and states as his belief that there are. For instance, the irritation or excitation of a sensory epithelial cell in the retina passes to a number of pyramidal cells, and a sensation occurs from the combined action of these pyramidal cells. By means of collateral and protoplasmic processes the association of ideas is produced. He does not share Duval's and Rabl-Rückhard's view that the nerve-fibrillæ during sleep retract and thus sever the connection which they had (by contact) with the cell-body and its protoplasmic processes. [During waking hours the processes of the cells were supposed to lengthen and expand, and again come in contact with the cells.] Such an ameboid movement cannot be demonstrated objectively. He points out that the nerve-terminals in the olfactory bulb, cerebellum, optic lobe, etc. always have the same form and extent, and bear the same relation to the cells, no matter what may have been the cause of death; further, that the nerve-terminals in the retina and optic lobes of reptiles and batrachia always present the same appearance whether the animals had been active or the reverse just before death. He, however, believes that certain neuroglia-cells change their form during mental activity, for at times the processes are short and thick; sometimes they are longer and provided with numerous secondary and tertiary

[3] Sitzungsber. des Ver. f. Wissensch. Heilk. zur Königsberg, Jan. 6, 1896.
[4] Rev. de Med. y Cirurgia practicas, 1895, and Neurolog. Centralbl., 1895.

processes. He does not believe that neuroglia-cells serve the purposes of nutrition or support of the nerve-cells, and gives cogent reasons for this belief. He subdivides neuroglia-cells into 3 classes: 1. Neuroglia-cells of the white substance; these are large fixed cells with sharply-marked, straight processes; their function seems to be to act as a poorly conducting substance between the currents of nerve-irritation. 2. Perivascular neuroglia-cells, found near the capillaries of the gray substance and sending processes to the outer surface of the endothelium. The function of these cells is to cause dilatation of the vessels, and thus hyperemia in certain physiological acts; 3. Neuroglia-cells of the gray substance, sometimes stellate, at other times elongated in form. Their processes have many collaterals. In these cells there may be observed two states—1 of contraction, in which the processes are shortened and the secondary branches disappear; they may be compared to the pigment-cells in the skin of many animals. By the retraction of these processes, which usually occurs by an act of the will, he supposes that the nerve-cells and their processes, which had been kept apart by the neuroglia-processes, come in contact with one another, and thus the brain passes from the resting into the active state. In the other state, that of relaxation of the glia-cells, in which state the processes of the cell pass between the nerve-cells and fibrillæ and act as insulators of the nerve-current and prevent its passage, the brain is put in a condition of quietude *or sleep*.

Hypoglossal Nerve.—Froriep and Beck[1] have examined the medulla in a large number of mammals, including man, with reference to the existence of a dorsal root of the hypoglossal nerve. In artiodactyls, carnivora, and other groups they always found a well-marked dorsal root. In certain other groups the dorsal root is much reduced in size, and in some is absent. The hypoglossal nerve thus resembles a spinal nerve. The first cervical nerve also shows a tendency to decrease in the development of its dorsal root.

Nerves of Diaphragm.—The fact that the intercostal nerves send branches to the diaphragm, though long known, has sometimes escaped mention in text-books. Cavalié[2] has carefully dissected the parts in 6 subjects, and finds that the 6 lower intercostal nerves, while piercing the diaphragm to enter the abdominal walls, give branches to it. The 7th, 8th, and 11th are the most important, some of the others not always supplying branches. These muscular branches are distributed to only a small area of the diaphragm.

Superficial Nerves of the Head.—Frohse[3] in a monograph has given a very excellent description of the superficial nerves of the head. He finds, of course, many variations in different individuals. The two sides of the head often differ from each other considerably. These variations serve to explain the discrepancies that exist in the descriptions and diagrams of Merkel, Hasse, and other modern writers. Frohse makes use of the new anatomical nomenclature adopted by the German Association of Anatomists. He gives [very appropriately, we believe] a special name, ramus maximus nervi

[1] Anat. Anz., Bd. x. No. 29. [2] Jour. de l'Anat. et de la Phys., No. 2, 1896.
[3] Die Oberflächlichen Nerven des Kopfes, Berlin, 1895.

facialis, to that branch of the facial which accompanies the duct of Stenson. The network of nerves on the buccinator muscle he calls plexus buccalis. The communications that exist between the facial and trifacial nerves he regards as crossings or decussations, not as true anastomoses.

Vagal Nucleus.—Grabower[1] insists that there is no connection between the nucleus ambiguus of the vagus and the nuclei of the spinal accessory, and that it is very probable that the vagus, and not the spinal accessory nerve, as has been affirmed by some writers, is the motor nerve of the larynx.

Flocculus.—Bruce[2] has investigated the connections of the flocculus, and found that in a 6½-months-old fetus all the myelinated fibers of the flocculus passed inward toward the nuclei of the auditory nerve in the floor of the 4th ventricle. Part of the fibers of the peduncle of the flocculus end in the external auditory nucleus, but the greater number pass beneath the floor of the 4th ventricle and terminate in the internal auditory nucleus; a small number of fibers end in the nucleus of the 6th nerve, and perhaps a few pass to the formatio reticularis of the same side.

Medullated Fibers of the Brain.—Kaes[3] has investigated the topography of the medullated fibers in the brain, and particularly those of the cortex, by the use of the Weigert stain. He has also made estimates of the amount of cortical tissue present, and gives extensive tables. He hopes that by studies of this sort differences between the cortices of civilized and of uncivilized races may be determined, and that the differences existing at various periods of life may be ascertained. He concludes that the entire cortex has the property of filling itself with medullated fibers. They are most abundant in the motor region, in the occipital and temporal regions—*i. e.* in those portions which are known to be the centers of various functions. He believes that the higher intellectual faculties have their location particularly in those parts of the cortex where the sense-centers are located, and from which the brain sends out its orders centrifugally.

ORGANS OF THE SPECIAL SENSES.

The Ear.—His[4] has made some interesting observations on the anatomy of the osseous part of the organ of hearing of the great musician Bach. Among the facts noted are that the petrous portion of the temporal bone was unusually hard; the fenestra rotunda lay more nearly in the sagittal plane of the body, and was 2½ mm. in diameter; the usual diameter is 1½ mm., according to Krause. The first turn of the cochlea was very large. The eminence produced on the anterior surface of the petrosal by the superior semicircular canal was very well marked.

Organ of Jacobson.—Anton[5] has studied the organ of Jacobson in man. It consists of a grooved portion and a canal. The canal has an

[1] Berl. klin. Woch., Dec. 23, 1895.
[2] Brain, 1895.
[3] Wien. med. Woch., No. 41, 1895.
[4] Abhandl. der Math. Phys. Cl. d. K. Gesellsch. d. Wissensch. zu Leipzig, Bd xxii. No. 5.
[5] Zeit. f. Heilkunde, Bd. xvi.

enlargement with a number of diverticula. The length of the groove in the specimens examined was .46 mm., that of the canal 4.19 mm., on the average. The character of the epithelium in the grooved portion is like that of the regio respiratoria of the nose. In the canalicular part the cells, which rest on a basement membrane, are lower; the mode of transition of the various kinds of epithelium into one another, however, varies in different organs. The epithelium on the mesial wall was higher than that on the lateral, as has been affirmed by Kölliker and Merkel. The glands opening into the organ are saccular mucous glands. Anton examined 5 cases in which that portion of the nasal septum with which this organ is in relation was destroyed by pathological processes, in order to determine whether in these cases there was any disturbance of the sense of smell. No such disturbance was found, and he inclines to the view that the organ of Jacobson in man is quite rudimentary and has no function.

Conjunctival Glands.—Theodoroff[1] says the presence of the sebaceous gland of the conjunctiva described in 1859 by Manz has been denied by many authors; he has found them both in embryos and in adults. There are from 18 to 30 of them in each lid; they are distinct from the tubular glands of Henle, and of varying size, some being oval, others round, with a central opening. They are white in color. They are more abundant in the tarsal conjunctiva, and are situated just beneath the epithelium. They are saccular glands; their lining epithelium is stratified cylindrical in character, and the sacculi contain cells and detritus.

Central Artery of Retina.—Deyl[2] has examined the position of entrance of the central artery of the retina into the optic nerve in 21 injected and 8 uninjected preparations, and finds that the vessel invariably enters the nerve in its lower and inner portion or quadrant. That this is the case in the human embryo and also in the eyes of other vertebrates was well known. However, some of the recent works upon anatomy and ophthalmology state that in the adult the artery enters the nerve in the lower and external quadrant. Vossius assumed, in order to account for this seeming difference, that the embryonic eyeball underwent a rotation through an arc of 90°. Deyl shows that the assumption of Vossius is erroneous, as is also the belief that the macula lutea and fovea centralis are remnants of the cleft in the secondary optic vesicle.

Decussation of Optic Nerve.—Kölliker[3] states that in the optic chiasm there is a complete decussation of the fibers of the optic nerve in many mammals, including man (the chiasm of the dog, fox, rabbit, cat, and man was examined). It has long been known that decussation is complete in fishes, amphibians, reptiles, and birds. Kölliker is uncertain as to whether or not a few very small bundles may or may not remain uncrossed. Scheel in 1874 and Krause in 1876 have claimed that complete decussation occurred. It remains to positively prove or disprove these assertions.

Rods and Cones.—Norris[4] has continued his investigations of the retina,

[1] Centralbl. f. Prakt. Augenheilk., xxix., 1895
[2] Anat. Anz., Bd. xi.
[3] Berl. klin. Woch., May 11, 1896.
[4] Trans. Am. Ophth. Soc., 1895.

and reiterates his former views that the external extremities of the cones and rods are loops, the outer member of a cone bending over to become continuous with the outer member of an adjacent rod, or, less frequently, with the outer member of an adjacent cone ("twin cones" being thus formed). Adjacent rods unite also by their curved outer segments, ending in peripheral loops.

Larynx and Lungs.—Reinke[1] describes 2 folds of the mucous membrane of the true vocal bands—1 on the upper, the other on the lower surface. These folds, which he calls lineæ arcuatæ superior et inferior, divide the upper and lower surfaces of the cord into a mesial and a lateral portion. In artificially-produced edema of the larynx they are most conspicuous.

Pulmonary Alveoli.—Hansemann,[2] after having killed small animals with carbonic-acid-gas inhalations, and injecting the trachea with gelatin and Berlin-blue, stained the sections with acid fuchsin and picric acid. Thread-like communications of the injection-mass between adjacent alveoli could then be seen. He calls these pores between the normal pulmonary alveoli.

GENITO-URINARY ORGANS.

Position and Form of the Kidneys.—Helm[3] has investigated the position of the kidneys in 104 subjects; among his results are the following: In females the kidneys, as a rule, are lower than in males, the difference amounting to about one-half the depth of a lumbar vertebra. In females also extreme variations in position are more common than in males. The upper end of the kidney usually corresponds to the articulation of the 11th or 12th rib to the vertebræ, being more often at the 11th rib in males and at the 12th rib in females. He found accessory renal arteries in 1 of every 3 subjects. Increase in size of the liver does not tend to push the kidney down, but when the liver is decreased in size the kidney seems to be higher. Increase in the size of the spleen is capable of displacing the left kidney; gastrectasis, herniæ, enteroptosis, prolapse of the uterus, and deformities of the chest and vertebral column may also displace the kidneys. Cunningham[4] states that the lower end of the kidney is much more variable in position than the upper end; he also finds that the spleen makes an impression on the *anterior surface* of the organ, *not* on its lateral aspect, as affirmed by His. Cunningham[5] also describes the complicated relations of the kidneys in detail. He finds that the impression of the last rib on the organ is often met, and occasionally small depressions made by the ends of some of the transverse processes of the vertebræ. The convexity of the anterior surface of the kidney is seemingly due, during life, to the presence of a transverse ridge which is situated between an upper and a lower oblique portion.

Malformations of Penis and Urethra.—Kornfeld[6] describes a case of epispadias glandis et penis with an undivided prepuce. The penis, which

[1] Fortschritte der Med., Bd xiii. No. 12.
[2] Sitzungsber. d. K. Preuss. Akad. d. Wissensch. zu Berlin, No. xliv.
[3] Inaug. Dissert., Berlin, 1895.
[4] Jour. Anat. and Phys., vol. xxix. p. 512.
[5] Ibid.
[6] Wien. med. Woch., No. 51, 1895.

was of normal size, was twisted on its long axis, so that the urethral opening looked to the left; this was due to a difference in the development and mode of attachment of the corpora cavernosa. The defect, which was covered by the intact prepuce, involved the glans and extended for a distance of 1½ cm. upon the body of the penis. The other external genitalia were normal. The author calls attention to the fact that in all cases of epispadias extending beyond the glans that have hitherto been reported the prepuce was also cleft.

Double Penis.—Küttner[1] describes a case of true double penis; both penes and both urethræ were normal and alike. The bladder was single and normal in conformation. The division of the urethra into two began just beyond the opening of the ejaculatory ducts; a small communication between the rectum and urethra existed. The scrotum was double, but there was only one testicle on each side. The explanation of the anomaly is to be sought in a duplication of the *anlage* of the penis—*i. e.* of the genital eminence—and of the parts developed from it. Ballantyne and Skirving[2] give a short description of the cases of double penis which have been recorded. They find duplication of the penis in an otherwise "single" individual to be a very rare anomaly, some 20 cases having been met in medical literature. Anomalies associated with it, as atresia ani, may prove dangerous to life. The urine may escape from one penis or from both, or it may pass through a perineal opening. In most of the cases there has existed sterility or impotentia coeundi. Defects in the prepuce usually coexist. The degree of duplication varies much; the two organs may be placed side by side or one may be in front of the other. As to size, they may or may not be equal. The scrotum varies in form; it may be cleft. The testicles are usually 2 in number; they may or may not have descended. The prostate and seminal vesicles vary in development. Associated with diphallism there may be atresia ani, partial or complete division of the bladder into two parts, double urethra, increased width of pelvis, together with a defective symphysis pubis, and hernia of some of the abdominal contents into a perineal pouch. Rarely there coexists duplication of the heart, stomach, and other viscera.

Infundibulopelvic Ligament.—Durand[3] gives a description of the relations and of the mode of development of this ligament. This structure, which Durand calls the ligamentum ileoovaricum or ligamentum appendiculoovaricum de Clado, is present in both sexes, though of course it is more developed in the female. Morphologically, it is the peritoneal covering or mesentery of the Wolffian body, and represents the course taken by the ovaries from the lumbar region to the pelvis.

Fourchet.—The much-discussed question of the relation of the fourchet to the labia majora and to the nymphæ has been investigated by Blacker.[4] In 15% of 397 cases the fourchet was formed by the junction of the posterior extremities of the labia minora; in the rest of the cases it consisted of a fold of skin seemingly uniting the posterior extremities of the labia majora. He

[1] Beitr. z. klin. Chir., 1896, Bd xv. H. 2.
[2] Teratolgia, 1895.
[3] Prog. méd., 1895, No. 27.
[4] Jour. Anat. and Phys., Jan., 1896.

regards the fourchet as being a part of the labia minora, and would advise the abolishing of the terms "anterior and posterior commissures."

SKIN.

Papillary Ridges of Fingers and Toes.—Hepburn[1] has made some interesting researches on the papillary ridges on the hands and feet of man and monkeys. He finds, in general, that the arrangement of these ridges in the lower monkeys is much simpler than in man. In the orang and chimpanzee the plan of arrangement of the ridges more closely resembles that of man. These ridges of papillæ assist the prehensile function of the hands and feet and add to the sensibility of the part.

METHODS.

Method of Demonstrating the Medullated Nerves of the Skin.—Heller[2] gives the following method: After hardening the part in Müller's fluid and cutting sections with the freezing microtome, washing and placing in 1% osmic acid, the sections are placed in an incubator for from 24 to 48 hours at a temperature of 37° C. The sections are then put into the following mixture: Sodium sulphate 125 parts, sodium carbonate 70, distilled water 500, pyrogallic acid 15. This solution darkens the entire preparation, and this blackening continues, so that unless an oxidizing agent is resorted to the preparation is rendered useless. A solution of permanganate of potash is used for this purpose; in this the sections remain until they have become of a light-brown color. Then they are put into a 1–2% solution of osmic acid, after which they are of light yellowish-green color. They are then mounted in glycerin or Canada balsam. The medullated nerve-fibers in these preparations are of a deep-black color.

Formalin.—Gerota[3] states that one of the most valuable properties of formalin is the hardening of the organs which it produces, causing them to retain their natural position; if they are temporarily removed from their place, they will return to their former position. If it is desired to fix the organs in situ and to study them by ordinary dissection, the arteries are injected with 5 liters of a 15% solution of formalin. They are thus fixed in from 2 to 3 days, and acquire an elastic hardness; the body can be permanently kept and very neat dissections made. If frozen sections are desired, the vessels are injected with 4 liters of a 5% solution of formalin. After this the body is frozen. Immediately after making the sections they are put into a 4% solution of formalin, where they may remain for from 5 to 8 days to harden them still more. Before the parts are dissected they are washed in water to rid them of superfluous formalin, the vapor of which is very irritating to mucous membrane. By the above method the organs are hardened before sectioning, are harder than they can be made with alcohol, and less time is required; furthermore, the method is less expensive than the use of alcohol. A disadvantage

[1] Sci. Trans. of Royal Dublin Soc., vol. v. series 2, 1895.

[2] Berl. klin. Woch., Dec. 16, 1895, p. 1091.

[3] Anat. Anz., Bd. xi. p. 417.

of alcohol is that it dissolves the fat and causes the subcutaneous tissue to resemble a fascia; this is not the case with formalin, and so the study of the fasciæ is made easier.

To prepare microscopic topographic specimens of embryos and the new-born the carotid or umbilical arteries are injected with a mixture of 20 g. of formalin in 100 g. of 90% alcohol; for a 6-months' fetus 200 to 250 g. of this mixture are necessary. After the injection the entire fetus is placed in a 10% aqueous solution of formalin. After 4 or 5 days sections can be made with a sharp brain-knife. Very good preparations of the fetal brain can be obtained in this way. For the literature on formalin see Anat. Anz., Bd. xi.

MISCELLANEOUS.

Pithecanthropus Erectus.—Concerning the remains found by Dubois in Java (see the *Year-Book* for 1896) there has been a great deal of discussion, and the differences of opinion among anatomists, zoologists, and anthropologists are so great and irreconcilable that no definite statement can as yet be made as to what Dubois has really discovered. As Virchow says, it will be necessary to await the finding of further remains in the East Indies and Sunda Islands before positive conclusions can be reached.

Congenital Deformities of the Extremities.—Lewin[1] divides supernumerary little digits (fingers and toes) into the three following classes: 1. Those that articulate with a separate metacarpal or metatarsal bone; 2. Those that articulate with the metacarpal or metatarsal bone of the fifth digit; 3. Those which have simply fibrous or ligamentous connection with the fifth digit. Those of the first kind are constantly supplied with tendons; sometimes tendons are found in the second class, though never in the third class; these tendons do not, however, permit of an independent movement of the digits. Nerves are always present.

Joachimsthal[2] reports, among other cases of **congenital deformities of the extremities,** one in which the humerus was entirely absent, the normal hand being joined to the scapula by a radius and ulna. In the same journal is recorded a case of a 6-days-old girl in whom the right femur was represented by a bony mass 3 cm. in length.

Absence of Abdominal Muscles.—Parker[3] describes the case of an infant in whom some of the muscles of the abdominal wall were absent, the parietes being as thin as parchment; only the upper and lower ends of the rectus were present; no other muscles were found anteriorly. The muscles of the back were normal. Langton also referred to a case in which the abdominal wall consisted only of skin and subcutaneous fascia.

Gynecomastia.—Stieda[4] has examined 2 cases of this anomaly histologically. Both were males, aged 23 years. In 1 case the gynecomastia was single, in the other double. The gland had been removed on account of the subjective symptoms caused by it. Stieda finds that there is no histologic cor-

[1] Virch. Arch., cxliii. 2, 1895.
[2] Deutsch. med Woch., No. 12, 1895.
[3] Lancet, 1895.
[4] Beit. z. klin. Chir., Bd xiv. H. 1.

respondence, or even resemblance, between the breasts of cases of gynecomastia and the functionating female breast. The condition consists in a hyperplasia of all the components of the male gland, particularly of the connective tissue. The gland-ducts present clubbed diverticula or outgrowths, but they are not sufficiently developed to justify one in calling them acini.

Plasma-cells.—Hodara[1] discusses the question as to whether the plasma-cells of Unna are found in the organs of the hematopoietic system, as has been maintained by some investigators. He examined a considerable number of specimens of spleen, lymph-glands, and bone-marrow and failed to find the plasma-cells in normal organs. Cells which resemble them are met with; these he classes with the large mononuclear leukocytes. He regards the plasma-cells of Unna as pathologic products, either from a connective-tissue cell or from leukocytes.

Thymus.—The fact that the thymus partially persists throughout life, though of course in a very much modified form, was first clearly shown by Waldeyer. Sultan[2] describes the changes which the organ undergoes. In an infant 9 weeks old he found the remains of a canal lined by columnar epithelium; he thinks that he also found remains of this canal in an individual 50 years of age. This is the remains of the "anlage" of the gland. He found eosinophile cells in the periphery of the acini in the young thymus. Concerning the histologic changes in the involution of the gland, he states that epithelioid cells, derived from the endothelium of small vessels and from other connective-tissue cells in their vicinity, appear in the acini and replace the original cells. These epithelioid cells become converted into fat-cells. In the later stages the lymphoid cells become completely replaced by spindle-cells, and epithelioid cell-groups appear, giving the organ the appearance of a gland.

Glandulæ Parathyroideæ.—Schaper[3] states (see also *Year-Book* for 1896) that the so-called external epithelial bodies found in the neighborhood of the thyroid gland and in the vicinity of the carotid artery of certain mammals, including man, are detached portions of the developing lateral portions of the thyroid gland; these detached portions have remained behind in their development. Usually they remain in their rudimentary state, but they may under certain circumstances develop into tissue more closely resembling the thyroid. Alveoli may form or a pathologic cystic degeneration may occur. The "internal epithelial body" of man is capable of giving rise to functionally active thyroid-gland tissue. Schaper regards both the internal and external epithelial bodies as morphologically identical, representing masses of tissue which have in some way become detached from the developing thyroid gland and persisting in their embryologic condition.

PHYSIOLOGY.

By G. N. STEWART, M. D.,

OF CLEVELAND, OHIO.

Epitome.—The following are a few of the more important investigations referred to in the accompanying article: The proof that fibrin-ferment is a nucleoproteid (Pekelharing and Halliburton); the evidence given by Gryns, Cowl, and others that the centrifugal method of determining the volume of the blood-corpuscles (by the hematocrite) is capable of accurate results; the discussion by Winter, Koeppe, and others of the relations of osmosis to physiologic processes, including the formation of the HCl of the gastric juice; Porter's demonstration of the existence in the vagus of vasomotor nerves for the heart; the experiments of Oliver and Schäfer on the internal secretion of the suprarenal and other glands; Schöndorff's researches on urea; the demonstration by Kunkel and others of the absorption of inorganic iron; Lohnstein's modification of Roberts' method of estimating sugar in the urine for clinical purposes; the proof afforded by Nuttall and Thierfelder that the intestinal bacteria are not essential to life and growth; the investigations of Chittenden and Mendel on the influence of alcohol on artificial digestion; Haldane's researches on carbon-monoxid-poisoning; the experiments of Schumburg and Zuntz on the cause of mountain-sickness and the changes in gaseous metabolism at high altitudes; the work of Filehne and Kionka on the mechanism by which the respiratory activity is increased during muscular exertion; the demonstration by Goltz and Ewald that various functions (in the dog) are unaffected by the absence of large portions of the spinal cord; Strehl's discussion of the functions of the labyrinth; and the evidence adduced by v. Kries, from investigations on color-blindness, in favor of the Young-Helmholtz theory of color-vision.

BLOOD, LYMPH, AND CIRCULATION.

Coagulation of the Blood.—[During the past year our knowledge of this subject—one of the dark places of the earth from the physiologic standpoint—has made material progress.] The friendly controversy which for several years has been maintained between Halliburton and Pekelharing as to the precise chemic nature of the fibrin-ferment has at last been settled by the admission of the former[1] that fibrin-ferment and the similar or identical substances which can be obtained from masses of adenoid tissue like the thymus or from the stromata of the red blood-corpuscles are nucleoproteids. [Another

[1] Jour. of Phys., Sept. 5, 1895, p. 306.

discussion of equal interest, and perhaps not less fruitful, on the role of the calcium salts in coagulation, has been brought to a less fortunate termination by the lamented death of one of the disputants, Alexander Schmidt. Schmidt maintained that the action of soluble oxalates in preventing coagulation was due to a specific anticoagulant power, and not to the precipitation of the salts of lime.] Arthus [1] in an elaborate investigation has [in our opinion] successfully defended the position that oxalated blood loses the power of coagulation, not because it is oxalated, but because it is decalcified. Lilienfeld [2] restates his position on the question of coagulation. In brief, he supposes that fibrin is formed by the union of calcium and thrombosin, a substance derived from the splitting up of fibrinogen under the influence of nucleoproteids set free from the broken-down leukocytes. [While, on the whole, his theory takes adequate account of the calcium and fibrinogen as factors in the formation of fibrin, and can be readily translated into terms of Pekelharing's scheme], he asserts [but without sufficient evidence], in opposition to the ordinary view, that fibrin-ferment is not a forerunner, but a product, of coagulation. [However this may be, we can no longer look upon the action of the nucleoproteids as a unique and specific action.] Gelatin (Dastre and Floresco [3]) and certain colloids prepared by synthesis (Halliburton and Pickering [4]), have been shown to possess a similar power of causing intravascular coagulation. Not only so, but gelatin also acts as a coagulating agent outside the vessels; and, while it does not hinder the anticoagulant action of oxalates, it antagonizes the proteoses. As to this anticoagulant action of proteoses, Ledoux [5] adopts the view that injected proteoses acquire their peculiar powers after undergoing modifications in the organism. Contejean,[6] on the other hand, thinks it more probable that the anticoagulant substance is secreted as one of the products of the reaction of the organism, and has no other relation to the injected proteoses. The assertion of Gley and Pachon [7] that a normal condition of the liver-cells is essential to the action of peptone (proteoses) on coagulation, and that ligation of the portal lymphatics renders the subsequent injection of peptone ineffectual [a statement which certainly lent strong support to this view of Contejean], has been contradicted by Starling [8] [and may, we believe, be considered devoid of foundation].

Formation of Red Blood-corpuscles.—Neumann [9] continues his valuable histologic researches on the formation of the red corpuscles. He finds, in confirmation of the results of Marquis, that in frogs in the spring and early summer the blood-forming activity of the red bone-marrow experiences a sudden increase; and, in agreement with Kölliker, he traces the genealogy of the newly-formed corpuscles back to the mononuclear leukocytes or lymphocytes. Danilewski [10] states that after injection of extracts of spleen and bone-

marrow into the peritoneal cavity the number of red blood-corpuscles is increased. [But while this result is not in itself unlikely, since such extracts contain organic iron, the fact that no systematic estimations of the specific gravity or the total solids of the blood were made renders it impossible to say how far a mere change in the concentration of the blood might have caused an apparent increase in the number of the corpuscles. And we know that the specific gravity of the blood may be altered by various circumstances; *e. g.*, as shown by Moikowski,[1] by stimulation of the vagus. The same omission somewhat diminishes the value of the interesting experiments of Southgate[2]], who estimated the volume of the red corpuscles (by centrifugalization in the "hematocrite") before and after injection of blood into the peritoneal cavity. He found, in accordance with the statements of Hunter, Ponfick, and others, that the richness of the blood in corpuscular elements is rapidly increased after the injection, reaching its maximum in as short a period as 3 hours.

Estimation of the Volume of the Corpuscles.—Hedin[3] and Koeppe,[4] continuing their previous work, have demonstrated that it is only salt-solutions of the same osmotic tension as the serum [*i. e.* which contain the same number of molecules per unit of volume, or, what is tantamount to this, have the same freezing-point] which do not alter the volume of the red corpuscles as determined by the hematocrite. It has been shown by Eykman[5] that the 0.6% NaCl solution used by Bleibtreu for diluting the blood in his [chemic] method of estimation gives an erroneous result, owing to the absorption of water by, and consequent increase in the volume of, the corpuscles. Hedin[6] has stated that not a 0.6% solution of NaCl, but a 0.96% solution, is isotonic with the blood of the ox, and Gryns,[7] that a 0.88 to 0.84% solution is isotonic with human blood. Bleibtreu[8] has indeed admitted that his solution was not, and must be made, isotonic with the blood, and he also withdraws his former unconditional condemnation of the centrifugal method, which he allows to be capable, with proper precautions, of yielding good results. This is also the conclusion [and to it we adhere] of Gryns[9] and Cowl,[10] both of whom lay stress upon the necessity of using accurately-made mixing solutions. The formula recommended by the latter is sodium oxalate 2 parts, NaCl 1 part, aq. dest. 1000 parts.

Osmosis and Lymph-formation.—[On this subject and on the cognate topic of absorption from serous cavities and connective-tissue spaces the annual crop of important and interesting papers has again been very large. The investigations of de Vries, Van't Hoff, and others in the domain of molecular physics have given to our notions of osmosis the precision which was wanted before its relation to many physiologic processes could be profitably discussed. In particular, Van't Hoff's discovery that the osmotic pressure depends on,

and is proportional to, the number of molecules dissolved in a given quantity of the solvent and to the absolute temperature, and the method elaborated by Raoult of determining the molecular concentration of a solution from the difference between its freezing-point and that of the solvent, have found fruitful application in the hands of numerous workers.] Winter[1] has found that blood-serum, milk, and 0.91% NaCl solution freeze at the same temperature (— 0.55°)—*i. e.* are equimolecular or isotonic solutions. The serous fluids, such as pleuritic, ascitic, and hydrocele fluids, oscillate within narrow limits about the same mean of — 0.55° ; *i. e.* they are approximately in equilibrium with the blood.[2] On the other hand, the "functional liquids," such as gastric juice and urine, have a molecular concentration usually far removed from that of the blood-serum. Accordingly, equilibrium cannot exist between them and the blood ; and it is the absence of this equilibrium which, according to Winter, determines, on the one hand, the passage of liquid from the plasma to the urine, and, on the other, the passage of the gastric contents into the blood. By numerous determinations he[3] actually finds that the molecular concentration of the contents of the stomach at different stages of digestion varies between two rather wide but mathematically rigid limits: — 0.36°, which represents the limit of resistance of the cells, *i. e.* corresponds to the most dilute solution of NaCl with which cells such as the red blood-corpuscles can be placed in contact without being broken up, and — 0.55°, the molecular concentration of the blood-serum. He attributes great importance to the inorganic constituents of the physiological liquids, and particularly to the NaCl, which furnishes two-thirds of the molecules that circulate in the blood and lymph. [The author of these brilliant and suggestive papers speaks of such physiological processes being "compelled by blind osmotic laws," but it has not escaped him (although we doubt whether he has given due weight to this consideration) that behind the uniformly acting osmotic laws we come again upon the diversity of life so soon as we ask the question, How is it that the contents of the uriniferous tubules and of the stomach are kept at a molecular concentration so different that osmosis can cause in the one case a constant outward stream of waste material, and in the other a steady inward flow of food-substances? This is a question which we may put, but which Winter does not answer ; and we are thus again thrown back upon specific cellular powers.]

Lazarus-Barlow[4] has emphasized the importance of attending to the initial rate of osmosis rather than the final osmotic pressure [the latter being what is deduced from the freezing-point] in considering the bearing of osmosis on physiologic processes, and particularly on the vexed question of the mechanism of lymph-formation.

Cohnstein[5] states that the maximum concentration of the lymph after injection of substances like NaCl and sugar never exceeds that of the blood-serum, as Heidenhain asserted. He points out [and in this he is undoubtedly

[5] Pflüger's Arch., Bd. lxii., 1895, p. 58.

right] that Heidenhain's comparison of samples of blood and lymph taken simultaneously was an improper procedure, for the lymph flowing at any given moment from the thoracic duct is lymph which has been formed from the blood, not at that moment, but at some unknown earlier period. And although Mendel[1] has found occasionally, after intravenous injection of NaI, a greater maximum concentration of it in lymph than in blood, Cohnstein[2] has traced this result to the fact that Mendel allowed an appreciable interval to go by, after completing the injection, before he determined the amount of NaI in the blood. Some of the injected salt would therefore have time to pass from the blood into the lymph. [It is perhaps an equally important source of error that, with the large quantities of NaI injected, the osmotic pressure of the blood would be considerably increased; and] Leathes[3] has shown that an increase in the osmotic pressure of the blood is compensated very rapidly by the inflow of liquid from the tissues.

Starling[4] asserts, in support of the physical theory, that even salt-solutions isotonic with the blood-plasma can be absorbed by the blood-vessels in virtue of the osmotic pressure exerted by the proteids of the plasma [which although very much less than that of substances like NaCl, for membranes like ferrocyanide of copper, impermeable both to crystalloids and colloids, is relatively considerable for membranes, such as the capillary walls, which can be readily traversed by the crystalloid molecules, with difficulty by the colloids].

On the other hand, Ostowsky[5] finds that the flow of lymph from the testicle is increased by intravenous injection of minute doses of pilocarpin, while the arterial pressure is unaffected. [The suggestion that pilocarpin acts on the capillary endothelium as it does on the cells of the salivary and other glands would carry more weight, however, if changes in the capillary pressure could have been controlled by simultaneous observations of the blood-pressure in the veins of the organ.] Lazarus-Barlow[6] sums up strongly against the physical view. Among other conclusions he points out—(*a*) that the maximum outflow of lymph does not occur at the time of maximum intravenous pressure; (*b*) that in the great majority of his experiments the injection of a concentrated solution of NaCl, glucose, or urea was followed, not by an initial diminution in the outflow of lymph from the thoracic duct [as might have been expected if a rapid transference of water from the tissue-spaces to the blood took place], but by an immediate increase. Tscherewkow[7] ranges himself also on the "vitalistic" side on the strength of experiments in which the blood-pressure was reduced by hemorrhage without any marked diminution in the outflow of lymph. [On the whole, it may be said that the general trend of research is at present to abridge to a certain extent the field of specific vital action so far as the capillary endothelium is concerned, and to correspond-

ingly enlarge the "sphere of influence" of the more purely physical processes of filtration and osmosis.]

Absorption from Serous Spaces.—Heidenhain [1] offers a detailed [and, as it seems to us, convincing] criticism of Cohnstein's attack [2] on the conclusion of Orlow,[3] that absorption of soluble substances from the peritoneal cavity takes place essentially through the blood-capillaries. Cohnstein asserted that the absorption was due solely to the lymphatics—a view which was also, though less uncompromisingly, put forward by Starling and Leathes.[4] Everybody is agreed that solid particles find their way into the lymphatics of the diaphragm, passing, according to Muscatello,[5] between the endothelial cells or being carried in by leukocytes. Solutions, too, can be mechanically sucked into the lymphatics by the movements of the diaphragm, and, as Reibmayer and Höffinger have shown, absorption from the peritoneum is favored by massage. The same is true, according to Kellgren and Colombo,[6] of the absorption of liquids injected into the muscles and joints, and presumably of pathologic exudations. And they believe that the veins, as well as the lymphatics, are intimately concerned in this.

Vasomotor Nerves.—Porter[7] has demonstrated the presence in the cat's vagus of vasoconstrictor fibers for the heart. Bayliss and Hill [8] have reexamined the question of the vasomotors of the brain, and conclude [as we think, with good reason] that there is no evidence of their existence nor of the existence of any local vasomotor mechanism, such as Roy and Sherrington assumed. The volume of the brain is practically invariable. A rise in arterial pressure always causes an increase, and a fall a decrease, in the velocity of the blood-flow through the brain. They do not believe that the rise of arterial pressure in cases of increased intracranial pressure is protective, and the old treatment of lowering the blood-pressure by depletion and purgation is therefore the right one. Gulland,[9] too, from the histologic side finds no evidence of the presence of nerves in the walls of the cerebral blood-vessels.

François-Franck [10] has again attacked the problem of the existence of pulmonary vasomotor nerves. Recording the blood-pressure at the same time in the pulmonary artery, left auricle, and aorta, he comes to the conclusion [a conclusion which, since the work of Bradford and Dean, can hardly have appeared doubtful to any one conversant with the subject] that vasoconstrictor nerves for the lungs exist and can be reflexly excited in various ways. He sees in reflex spasm of the pulmonary vessels, associated with inhibition of the heart, the conditions that determine acute dilatation of the right ventricle in certain painful affections of the abdomen. Reflex spasm of the pulmonary vessels and constriction of the bronchi are also essential elements in the production of reflex asthma.

Werziloff[1] states that vasodilators for the skin of the posterior limb exist in the posterior roots of certain lumbar and sacral nerves. [This is a statement which has been previously made, but it cannot, as yet, be considered definitely proved. The same is true of] the assertion of Steinach and Wiener[2] that the posterior roots contain motor fibers for the intestines.

Hallion and François-Franck[3] have traced the vasoconstrictor fibers of the intestine from the spinal cord through the sympathetic ganglia into the splanchnics. The innervation of the smooth muscular tissue of the spleen has been investigated by Schäfer and Moore.[4] They find that while the rhythmical contractions of the spleen can be carried on independently of the cerebro-spinal and sympathetic nervous system, its volume can be profoundly influenced by nerves, both by vasomotor fibers which affect the general blood-pressure, and more directly by fibers which act on its unstriped muscular tissue.

The reflex fall of blood-pressure which, under certain circumstances—*e. g.* in chloroform or chloral narcosis—is known to result from stimulation of afferent nerves has been reinvestigated by Hunt.[5] He finds very strong evidence for the presence of depressor or reflex vasodilator fibers in the sciatic and other nerves. These seem to be readily excited in nerves that have been cooled, in regenerating nerves, and mechanically by the kneading of muscles. On the other hand, direct stimulation of the central end of muscular nerves always causes a rise of blood-pressure. [This fact was previously shown by the author of this abstract in conjunction with C. Ewald.]

Shields[6] has studied the effect of odors and mental work on the blood-flow by means of an improved plethysmograph and an elaborate arrangement which permitted the nostrils of the person under investigation being, so to speak, irrigated with odors from any one of 13 different taps, and then washed out by a stream of odorless air from a fourteenth. He finds that sensations, when they produce any effect at all through the vasomotor system, tend to diminish the volume of the arm. The same is the case with mental work. [But it is difficult, in the light of the results of Bayliss and Hill, quoted above, to admit, what Shields seems to suggest, that this diminution is caused by the withdrawal of blood to the brain, for the quantity of blood in the cerebral vessels can vary only slightly. It is therefore more probable that the diminution in the volume of the arm, if it is connected with changes in the cerebral circulation, is the local expression of a general vasoconstriction, and a consequent rise of arterial pressure, which would increase not so much the congestion of the vessels of the brain as the velocity of the blood in them.]

The Heart.—Porter[7] has continued his reinvestigation of the cause of the phenomena which follow complete or partial stoppage of the coronary circulation. He shows [and, we think conclusively], in opposition to the view of

Fenoglio and Drogoul,[1] of Tigerstedt,[2] and of Langendorff,[3] that none of the phenomena, not even the fibrillary contractions, are due to mechanical injury, but all to the cutting off of the blood-supply.

METABOLISM, NUTRITION, AND DIETETICS.

[In this department of Physiology the greatest amount of attention has again been given to internal secretion, and to questions connected with the formation and the fate of sugar in the organism.]

Internal Secretion; Suprarenal Capsules.—The important work of Oliver and Schäfer on the *suprarenal capsules*, to which we drew attention in the *Year-Book* for 1896, but which at that time had only been made known by a preliminary communication, has now been published in detail.[4] They conclude [and the conclusion seems warranted, at least provisionally] that one of the main functions, if not the main function, of the glands is to produce a substance which assists in maintaining the necessary muscular tone, and particularly the tone of the smooth muscle of the vascular system. Experimental removal of the capsules is followed by extreme weakness of the heart and loss of tone of the blood-vessels, in striking analogy with the symptoms that are known to accompany their degeneration in Addison's disease.

Cybulski and Syzmonowicz,[5] who have made an independent study of the same subject [although with more meagre results], assert [but, we believe, erroneously], in opposition to Oliver and Schäfer, that the marked rise of blood-pressure, caused by intravenous injection of suprarenal extract, is due to stimulation of the vasomotor center, and not to direct action on the vessels. They state that the active substance is a crystalloid with basic properties.

Dubois[6] comes to the conclusion that the function of the capsules is to destroy certain toxic substances, especially waste-products of muscular activity. There exist always, according to him, in the medulla of the glands, certain alkaloidal toxins [accumulated here, perhaps, in order to be destroyed?], and these are the substances which act so powerfully on muscular tissue and on certain nerve-centers. [It is evident that while this theory is diametrically opposed to that of Oliver and Schäfer, it is not irreconcilable with their experimental results; and, so far as we can see, further investigation is necessary to decide between the two.] That the suprarenals have some such poison-destroying function as Dubois has suggested is also indicated by the experiments of Boinet,[7] who finds that the usual causes of death after extirpation of the capsules (in rats) are (*a*) the accumulation of substances in the muscles, blood, etc., which produce toxic symptoms on injection into normal animals, and (*b*) pigmentary changes in the blood.

Thyroid.—[Recent work on the thyroid has in general raised more questions than it has settled.] De Dominicis[1] has endeavored, as others have done, to clear up a few of these. He finds that in quite exceptional cases (2 out of 29 dogs) the animals remain well after thyroidectomy. [Unfortunately, he did not determine whether in these cases accessory thyroids were present. The author of this abstract has found in a similar case a small body of thyroid structure in the neighborhood of the aortic arch.] He sums up by saying that the symptoms which follow thyroidectomy are those of autointoxication (of the nervous system) by poisons which, under normal circumstances, it is the office of the thyroid to destroy. A similar conclusion is reached by Blumreich and Jacoby,[2] who, however, report that in rabbits the so-called parathyroids have no histological resemblance, and probably no genetic relation, to the thyroid proper, and that their presence or absence does not affect the results of thyroidectomy. Notkin[3] goes so far as to announce that he has isolated from the thyroid certain toxic proteid substances which cause in animals symptoms similar to those observed after extirpation of the glands. [But the symptoms caused by thyroidectomy are by no means so definite and unmistakable as to render it unlikely that an observer, in making a generalization of this sort, may easily be led into error by an accidental and superficial resemblance.]

As to the precise nature of the therapeutically active substance in thyroid extracts many different statements have been made. Kocher,[4] under Drechsel's guidance, has isolated two crystalline and proteid-free bases, one of which is perhaps identical with the body discovered by Fränkel,[5] and named by him thyreoantitoxin. Baumann[6] has extracted a substance (thyriodin) containing iodin. All of these bodies are stated to have a favorable influence upon the symptoms induced in animals by thyroidectomy. [But we doubt whether a sufficient number of control-experiments have yet been made to test their efficacy, and thyroid-feeding *in animals* has usually been very unsuccessful; *e. g.* of several thyroidless dogs fed [by the author of this abstract] with fresh thyroids and commercial extracts not one survived]. And Edmunds[7] saved only 2 dogs out of 20. Gottlieb,[8] again, found thyriodin inactive, while a commercial preparation acted well.

According to Treupel,[9] thyriodin causes an increased nitrogenous metabolism in man, as do (in the dog) the thyroid tablets of Burroughs, Wellcome & Co. (Schöndorff),[10] and the glands themselves (Roos).[11]

Dutto and Lo Monaco[12] state that the injection of physiologic salt-solution into the vessels causes, along with transient amelioration of the cachectic symptoms, in thyroidless dogs an increase in the excretion of N; and from this they draw the conclusion [with considerable temerity, as it seems to us] that

in consequence of the loss of the thyroids a nitrogenous substance is held back in the organism and "washed out" by the injection.

Pituitary Body.—According to Oliver and Schäfer,[1] the action of extracts of the pituitary body is, upon the whole, similar to that of suprarenal extracts, except that there is no inhibition of the heart and that a much larger dose is required. There is no evidence that the pituitary can take on the functions of the thyroid after excision of the latter, and indeed the physiologic action of thyroid extracts is entirely different.

Testicle.—[Alternately ridiculed by the skeptics and overpraised by the fanatics, orchitic extract has, since Brown-Séquard's first announcement of its virtues, remained the *enfant terrible* of medical literature. A sober investigation of its physiologic action with the ordinary appliances of the laboratory is therefore a welcome contribution to our knowledge.] Such an investigation has been undertaken by Zoth[2] and Pregel,[3] who by means of ergographic experiments found, contrary to their expectations [a very important point in estimating the value of results obtained by the ergograph], that the power of muscular work was markedly increased (up to 50% of its initial value) by daily injections of the extract.

According to Legueu,[4] atrophy of the prostate occurs in dogs after castration, just as in man. Excision of the vasa deferentia, however, causes well-marked atrophy only in rare cases.

The Glycogenic Function of the Liver.—[In the *Year-Book* for 1896 we gave an abstract of Noël Paton's defence of the orthodox position, that sugar is normally formed in the liver, against the view so long identified with the name of Pavy. Since then Pavy[5] has answered Paton, and Paton[6] has replied to Pavy; but nothing has been said which makes it necessary to modify the opinion we then expressed, that the doctrine of Pavy is not supported by sufficient evidence.] Mosse[7] takes up a middle position between Pavy, who denies that the blood of the hepatic veins contains any excess whatever of sugar, and Seegen, who asserts that there may be twice as much sugar in the hepatic as in the portal blood. Using a method of catheterizing the hepatic vein [the priority of which he attributes to Abeles, but which we believe belongs to Pavy], Mosse concludes that while sugar is formed in the liver, the hepatic sugar is not the only source of the sugar of the blood. [This is a conclusion which may be formally correct, but the intimate relation between the liver and the sugar of the blood is sufficiently attested by the fact that after elimination of the liver the blood rapidly becomes free, or nearly free, from sugar (Minkowski, Seegen).] And a similar result follows such interference with the hepatic circulation as is caused by the ligation of the three chief arteries of the intestine (Tangl and Harley[8]) or removal of the whole of the abdominal viscera except the liver, even in a dog which has been previously

made diabetic by excision of the pancreas (Kaufmann[1]). Kaufmann,[2] while laying stress upon the liver as a sugar-forming organ, adopts the somewhat peculiar view that the larger part of the carbohydrate stored in the hepatic cells leaves the liver in the form of glycogen, which he easily finds in the plasma of diabetic dogs.[3] [Livierato and Lépine had already asserted its presence in small quantities in normal blood-plasma.] Dastre,[4] on the contrary, believes that this glycogen really belongs to the corpuscles. [And we think it can be confidently assumed that our present methods do not permit of the estimation of small quantities of glycogen with the accuracy which would be necessary to lend weight to Kaufmann's contention.] Kaufmann finds no support in his results for the view that in **diabetes** there is a diminution in the power of the organism to burn sugar. [But he seems to lose sight of the fact that in pathologic diabetes the behavior of the cells in presence of the sugar offered to them is certainly altered; and it is difficult to explain, on any other hypothesis than a change in their oxidative power, why in diabetes levulose should be burned in the body and dextrose excreted in the urine.] The discovery that in phloridzin diabetes (in rabbits) dextrose may be used up in large quantities (Lusk[5]) [only serves to accentuate the difference between this condition and pathologic diabetes. Indeed, so far is it from being certain that the drug has the same point of attack as the disease that] Zuntz,[6] after a survey of the literature, sums up by saying that phloridzin may quite possibly produce its effects by direct action on the renal epithelium.

Energy of Muscular Work.—[The source of the energy of muscular work is still the subject of keen debate. Pflüger has proved beyond all doubt that on an almost purely proteid diet (in a dog) work is done at the expense of the energy of proteid substances. But while it is true that on a mixed diet like the ordinary food of man somewhat more proteid may be used up during work than in repose (6 to 27% more in recent experiments by Krummacher),[7] it may be looked upon now as common knowledge that the greater part of the energy must come from the nonproteid food.] It is still open, however, to Pflüger to maintain, as one of his pupils (Schenck)[8] has lately done, that although the carbohydrates may very well be sources of muscular energy, they are never the *immediate* sources; that it is the organized "living proteid" molecule which actually breaks down in contraction; and that its nitrogenous nucleus is again regenerated to "living proteid" by union with nonproteid elements, and its store of energy recruited at their expense. Kaufmann's statement[9] that the amount of urea in the blood is not increased in passing through a muscle either during rest or activity [even if we could put any confidence in results that turn upon the estimation of minute quantities of urea] would prove little either for or against the position of Pflüger; while it is certainly true, as Speck[10] says, in bringing a long investigation to a close,

that "the researches of Pflüger show, indeed, that proteid *may* be [under all circumstances] the source of muscular energy, not that it *must*." [The most probable outcome of the whole discussion would seem to be that in this matter the organism is not controlled by hard-and-fast rules—by laws of the Medes and Persians which alter not—but that the living framework of the muscle, in which proteid is always an essential element, utilizes for contraction the materials that come most ready to its hand—nitrogen-free food *par excellence*, when, as in ordinary circumstances, this is abundantly offered to it; nitrogenous food when, as in an animal on a purely proteid diet, this is present in excess. As to the precise form in which the nonnitrogenous substances, whose combustion, on any hypothesis, plays ordinarily a most important part in muscular contraction are used up in the muscle] Seegen[1] has shown by calculation for the voluntary contraction of skeletal muscle, as Stewart[2] had previously done for the heart, that it is impossible to consider the muscular glycogen as an important source of muscular energy. The quantity present is too scanty, its disappearance too slow, and its renewal too tardy. On the other hand, Seegen[3] has made the paradoxical observation—which, however, has been criticised by Schenck[4]—that in a muscle tetanized artificially *more* glycogen disappears than corresponds to the amount of work done. [From this Seegen draws, curiously enough, the same conclusion as from the other set of experiments, in which too little glycogen was used up, viz. that glycogen cannot be the source of muscular energy—a conclusion certainly correct, but as certainly illogical.] Although it is not to be doubted that one of the most important substances used up in muscular contraction is sugar, the statement of Mosso, Harley,[5] and others, that sugar increases the capacity for muscular work, would still seem, in the light of the experiments of Langemeyer and Stokvis,[6] to await confirmation. Even when it has been proved, it must still be shown, before we can speak of sugar as "peculiarly a food for muscle," that this action differs from the action of caffein and cocain, which also, according to Sobieránski,[7] increase the muscular power, as measured by the ergograph.

Animal Heat.—Kaufmann[8] has measured simultaneously, for the first time (in dogs), the heat given off and the CO_2 and N eliminated. He professes to have made out that when, during digestion, sugar enters the blood in abundance, fat is plentifully formed, almost entirely from the proteid whose N is found in the urine. The greater part of the heat produced is derived from the oxidation of the sugar. When, during digestion, albumin enters the blood in abundance, it is immediately split up into fat, urea, CO_2, and H_2O. The greater part of the heat produced is in this case derived from the oxidation which transforms the albumin into fat, a smaller portion from the partial

oxidation of this fat. [Kaufmann's conclusions appear to us to be too "diagrammatic." The length of each experiment (5 hours) was too short, especially for the N-determinations, and the feces were altogether neglected.]

Pembrey and Hale White[1] assert that in hybernating animals the regulation of temperature is chiefly brought about by alterations in the production of heat in the muscles. Incidentally, they make the statement that the contraction of cardiac muscle is probably a much more economical process than the contraction of skeletal muscle—work, and not the production of heat, being the function of the former. [But, so far as we know, there is no foundation for assuming such a difference.]

Nitrogenous Metabolites.—*Urea.*—Schöndorff[2] by means of a new [and important] method finds that the organs (of the dog) contain, with the exception of the muscles, heart, and kidneys, nearly the same percentage of urea as the blood. In the blood the urea is uniformly distributed over corpuscles and serum. A most interesting result is the presence of urea in muscles.

Uric Acid and Xanthin-bases.—Krüger and Wulff[3] have founded a method for the quantitative estimation of the so-called alloxur bodies (uric acid + xanthin-bases) upon the fact that the xanthin-bases are precipitated along with uric acid by cupric sulphate and sodium bisulphite. If from the total N in this precipitate, estimated by Kjeldahl's method, the N belonging to the uric acid, as determined by the Ludwig-Salkowski method, is subtracted, the remainder gives the N belonging to the xanthin-bases, which in 19 analyses was found to vary from $\frac{1}{2}$ to $\frac{1}{7}$ of the N in the uric acid. Camerer,[4] while accepting nuclein as the forerunner of uric acid, in accordance with the researches of Horbaczewski, finds that the increase of uric acid and xanthin-bases in the urine after a meal is not to be wholly ascribed to the leukocytosis and consequent increase in the number of white blood-cells broken down during digestion. Some of the uric acid is derived from the nuclein of other cells, some from the nuclein of the food. In leukemia and in gout, according to Kolisch,[5] the increased formation of uric acid and xanthin-bases is also connected with the increase in the amount of nuclein set free from the broken-down leukocytes.

Fat.—Using the method of Dormeyer,[6] in which the tissue is subjected to gastric digestion before extraction with ether, Steil[7] finds that the percentage of fat in lean meat assumed by Voit in his extensive researches on metabolism is too low, and that Voit's results, therefore, require correction. Noël Paton[8] has investigated the relationship of the liver to fats. He brings forward evidence that fatty acids are formed in the liver from glycogen, but he finds no support for the old view that fat can be directly formed from proteids—a view

which Pflüger has recently subjected to adverse criticism, and which is also opposed to the experiments of Kumagawa and Kaneda.[1]

Iron.—The perennial question whether inorganic iron can be absorbed has been again attacked by Kunkel,[2] and answered [in our opinion decisively] in the affirmative. Hall[3] has actually been able, by microchemic tests, to trace an organic preparation of iron (carneferrin) from the intestine into the epithelium of the villi. Thence it passes into the blood of the portal vein, is partly used in the formation of Hb, and partly accumulates in the spleen and liver. Finally, Woltering[4] seems to have given the death-blow to Bunge's theory, that inorganic salts of iron only cause indirectly an accumulation of iron in the liver by uniting with the H_2S in the alimentary canal, and thus "sheltering" the organic iron of the food and permitting its absorption. For when $FeSO_4$ is given to rabbits, iron accumulates in the liver, but not when salts of manganese, which equally unite with H_2S, are substituted. Stockman,[5] making careful estimations of the quantity of iron in a number of actual dietaries, concludes that the greater part of it must be retained in the body and used over and over again. Stühlen[6] finds that the liver is especially rich in iron in pernicious anemia, and Auscher and Lapicque[7] have discovered in various organs in a case of pigmentary diabetes a hydrate of iron united with a very small quantity of organic matter.

Dietetics.—Ellinger[8] in view of Paal's[9] observations on the molecular weight of certain proteid substances, attempted to determine whether the organism has the power of making a synthesis of the large albumin molecule out of the comparatively small molecules of antipeptone. He concludes that this is not the case. On the other hand, according to Ganz,[10] more than half of the total N required can be given in the form of Paal's glutin-peptone [perhaps, if Ellinger is correct, in virtue of the hemipeptone in it. For the rest, although it is certain that peptones and albumoses consist of smaller molecules than albumin, it can hardly be said that we know definitely their relative, much less their absolute, molecular weights. Thus, while Paal gives the molecular weight of albumose at 1200 or 2100, and Sabanejeff that of egg-albumin at 14,000, Sjöqvist[11] gives 800, 600, and 250 as the molecular weights respectively of egg-albumin, albumose, and peptone.]

The Urine.—An attempt has been made by v. Sobieránski,[12] on the strength of a reinvestigation of the microscopic appearances presented by the kidney after injection of pigments into the blood, to revive Ludwig's theory of urinary secretion. Under no circumstances does he find the pigment-granules near the attached bases of the renal epithelium, but always near the lumen of the tubules; from which he concludes that the pigment is not passed

through the cells from the blood, but absorbed by them from the tubules after excretion through the glomeruli.

For the **clinical estimation of sugar in the urine** Lohnstein[1] recommends the following method [which appears to be based on sound principles, extremely convenient, and sufficiently accurate]: Add to about 50 c.c. of urine about 2 g. of yeast. Stir up, and determine the specific gravity of the suspension. Then pour into a flask, put in a cotton plug, and leave for 24 hours at 20–25° C. After fermentation is complete again determine the specific gravity. From the difference the quantity of sugar can be calculated. A special urinometer[2] is required.

Mörner[3] finds in every so-called normal urine a small amount of serum-albumin, the reactions of which, however, may be obscured by the presence of certain proteid-precipitating substances—*e. g.* nucleic acid. Albumosuria, according to Krehl and Matthes,[4] is most frequently, though not always, associated with fever. When the fever disappears the urine becomes free from albumose.

Abel[5] has discovered in the urine of the dog a volatile substance, with a penetrating odor, which contains sulphur, and which he has shown to be ethyl sulphide. It is absent from the feces, and is probably a product of normal metabolism. One or more closely-related substances (mercaptans) have been partially isolated by Aldrich[6] from the secretion of the anal glands of Mephitis mephitica (the common skunk).

DIGESTION AND ABSORPTION.

Gastric Digestion.—Moritz[7] states that the slight positive pressure (2–16 mm. of water in the sitting posture) which normally exists in the human stomach is chiefly due to the weight of the viscera, especially the liver, but in part also to the variable tonic contraction of the gastric walls. The pyloric end is the essentially motile part of the stomach, the fundus usually remaining at rest. In company with a chorus of other authors (Meltzer,[8] Goldschmidt,[9] etc.), Moritz asserts that faradic electricity has practically no effect on the movements of the stomach. Meltzer extends this conclusion to the intestines. His experiments lend no support to the idea that the movements of the alimentary canal can be influenced therapeutically by faradization.

Gastric Juice.—Schüle[10] finds that (in man) both the free and the combined HCl and the total acidity of the gastric juice undergo great variations even in the same (normal) individual without evident cause. It was not possible to raise the acidity distinctly even by the administration of as much as 1.4 g. HCl by the mouth. This is quite in accordance with the conclusions of Winter and Koeppe. Winter[11] says there should no longer be a question

[11] Loc. cit.

of excess or deficiency of HCl as a fundamental cause of dyspepsia. It is the total Cl, not the HCl merely, which is important, and all other dissolved molecules (sugar, peptones, etc.) take part in the digestive cycle. Only the molecules of Cl here, as in all animal liquids, are numerically preponderant. Koeppe[1] has given a novel view of the formation of HCl in the stomach. He believes that it is formed, not in the depths of the gland-cells, but at the surface of contact of the stomach-wall with the gastric contents, and that its source is none other than the NaCl of the food. The evidence adduced in favor of this view is very strong—*e. g.* when the chlorids are prevented from entering the stomach (v. Mering) no free HCl is found in it, not even after the injection of HCl into a vein. When NaBr or NaI is administered by the mouth, HBr or HI, acids analogous in constitution to HCl, appear in the gastric contents. Winter[2] also considers that his own results are a heavy blow to the theory of the intracellular formation of HCl.

Intestinal Digestion.—Nuttall and Thierfelder[3] have shown that by adopting elaborate precautions the alimentary canal of a guinea-pig, taken by Cesarean section from its mother's uterus and fed in an aseptic space on sterile milk, can be kept free from bacteria. The animal grew apparently as fast as one of its sisters which was brought up in the orthodox microbic way. With the success of this brilliant experiment the suggestion of Pasteur, that the presence of bacteria in the alimentary canal is necessary for digestion falls to the ground, at least so far as an animal diet is concerned.

From a study of the comparative anatomy of the bile- and pancreatic ducts in a large number of mammals Rachford[4] has made certain generalizations favorable to his theory of the mutual action of bile and pancreatic juice in the digestion of fats;[5] *e. g.* that a gall-bladder is necessary in animals whose food contains a considerable quantity of fat. [But Rachford does not bring into harmony with this conclusion the facts that among rodents the herbivorous rabbit, beaver, and porcupine possess a gall-bladder, which, on his hypothesis, must be to them an elegant superfluity, while the omnivorous rat has none, and that among the herbivorous ruminants the ox, goat, deer, and sheep are furnished with a receptacle for bile, while the camel, giraffe, and dromedary have to carry on the business of digestion without it.]

Pregel[6] asserts that in the intestinal juice of the sheep a large amount of urea (as much as 0.248 %) is present. [This statement must be received with reserve. One of his qualitative tests was the formation of the rhombic crystals of nitrate of urea. But without careful measurement of the angles this may be a very fallacious test.] Mendel[7] concludes [with good reason, we believe] that the so-called "paralytic secretion," after section of the intestinal nerves, is a true secretion and not a mere transudation.

Alcohol and Digestion.—The influence of alcohol, in various forms,

[1] Pflüger's Arch., Bd. lxii. p. 567.
[2] Loc. cit.
[3] Arch. f. (Anat. u.) Phys., 1895, p. 559.

[7] Ibid., Bd. lxiii. p. 425.

on artificial digestion, has been carefully studied by Chittenden and Mendel.[1] Alcohol in small amount (1 or 2% of absolute alcohol) does not diminish, and may even slightly increase, the activity of gastric digestion, and retardation is not very marked until 5 to 10% is reached. Strong alcoholic beverages retard gastric digestion in proportion to the quantity of alcohol present. With gastric juice in which the ferment is markedly active the presence of even 10% of whiskey, brandy, rum, and gin causes only a slight retardation, but with a weak gastric juice the effect is much more distinct. With 20% of whiskey the activity of the juice may be reduced $\frac{1}{4}$. Wines, as a class, hardly hinder gastric digestion, except in virtue of the solids contained in them. The same is true of malt liquors. On the proteolytic powers of the pancreatic juice absolute alcohol, whiskey, rum, and brandy have more effect than on the gastric juice. Wines, on account of the acids contained in them, retard pancreatic digestion much more powerfully than do the strong alcoholic liquors. On salivary digestion of starch wines have a similar effect and for the same reason.

RESPIRATION.

Schumburg and Zuntz,[2] with the view of elucidating the much-debated question of the cause of "mountain-sickness," have investigated the gaseous exchange during rest and work at 4 different levels, varying from 42 m. above the sea (Berlin) to 3800 m. (on Monte Rosa). While admitting that a final explanation is only possible after experiments more numerous and more varied, they bring forward strong evidence that changes in the mechanics, and not merely changes in the chemistry of respiration, are concerned. [And in this attitude of compromise we think they are right.] *E. g.*, they find that there is something not connected with the want of oxygen, which at high altitudes diminishes the capacity for muscular work, and at the same time affects the mechanics of respiration, while for a given amount of work an abnormally large consumption of oxygen is required. This "something" they suggest is the peculiar excitation of the nervous system in the fierce light of those high levels, which acts not only on the retina, but on the skin, and may even affect the distribution of the blood. [In this connection we may remember that, according to Tangl,[3] maximal stimulation of vasomotor nerves actually leads to changes in the gaseous metabolism.] The same stimuli, they think, may be the cause of the increase in the number of the red blood-corpuscles which is known to occur at high altitudes. Fick,[4] however, suggests that there are more corpuscles because they live longer when, so to speak, the wear and tear are lessened in consequence of the slower absorption of oxygen. That mere diminution of atmospheric pressure, as such (even to $\frac{1}{25}$ atmosphere), has no stimulating effect upon the neuromuscular system has been shown (for the frog) by W. Rosenthal.[5]

Haldane[1] has made an important contribution to our knowledge of the modus operandi of carbonic-oxid poisoning. The gas acts solely in virtue of its affinity (140 times greater than that of O) for Hb, which is thus rendered incapable of taking up O. Distinct symptoms are produced when the amount of CO in the air reaches about .05%. At .2% the symptoms become urgent. Since the time required for the symptoms to appear is [inversely] proportional to the rate of respiratory exchange per unit of body-weight, and is therefore much less in small than in large animals, he suggests that a mouse might be used as an "indicator" in a dangerous coal-mine. The poisonous action of CO diminishes as the partial pressure of O increases, and at a pressure of 2 atmospheres of O it is abolished in the case of mice, because the amount of O *dissolved* in the plasma is sufficient to sustain life.

A most interesting discussion has been carried on between Filehne and Kionka[2] on the one hand, and Zuntz and Geppert[3] on the other, as to the precise mechanism of the increase in the respiratory movements during muscular work. [Everybody is agreed that an increase in the respiratory movements is caused by tetanizing muscles whose nervous connections have been severed. Clearly, then, some alteration in the blood passing through the active muscles (the addition of certain hypothetical waste-products, according to Zuntz and Geppert) is concerned in the stimulation of the respiratory center.] And Zuntz and Geppert maintain that there are no grounds for the assumption that in the intact organism the changes are brought about in any other way. Filehne and Kionka hold it to be obvious that the increased "venosity" of the blood coming from the contracting muscles will directly affect the respiratory center. They assert, however, that when the muscular nerves have been cut tetanus causes a diminution of O and an increase of CO_2 in the arterial blood, while with intact nerves (as Zuntz and Geppert stated long ago) the arterial blood is even better oxygenated during tetanus than during rest. They therefore consider [and there seems no escape from this conclusion if the gas-estimations of Filehne and Kionka are accepted] that it is the function of some of the afferent muscular nerves to act upon the respiratory center so as to ensure that during contraction the supply of O shall *at once* become adequate to the demand.

Intercostal Muscles.—Masoin and Réné du Bois-Reymond[4] state that the intercartilaginous portions of the internal intercostal muscles take no part in ordinary breathing, but contract (simultaneously with the diaphragm, and therefore in the inspiratory phase) in forced respiration. Weidenfeld[5] makes the sweeping statement that the intercostal muscles as a whole take no part in respiration.

THE NERVOUS SYSTEM.

Spinal Cord.—Goltz and Ewald[6] have been able to keep dogs alive for

[1] Jour. Phys., July 18, 1895, p. 201, and Nov. 16, 1895, p. 430.
[2] Pflüger's Arch., Bd. lxii. p. 201, and Bd. lxiii. p. 234. [3] Ibid., Bd. lxii. p. 295.
[4] Arch. f. (Anat. u.) Phys., 1896, p. 85. [5] Centralbl. f. Phys., Nov. 30, 1895, p. 550.
[6] Pflüger's Arch., Bd. lxiii., May 13, 1896, p. 362.

long periods after preliminary section of the cord in the cervical region and subsequent removal of large portions of it. They find that even after destruction of the lumbar and sacral regions of the cord the external sphincter of the anus, striped and even voluntary muscle though it be, retains its tone, although this is temporarily lost after the first cervical section. The bladder ultimately recovers the power of emptying itself spontaneously and at regular intervals. A pregnant bitch from which the lumbar enlargement and the whole cord below it to the cauda equina had been removed, and therefore all the nerve-roots supplying fibers to the uterus cut, whelped in a normal manner, and the corresponding mammary glands behaved exactly as the rest. Digestion went on as usual when practically nothing of the cord except its cervical portion was left. Certain vasomotor phenomena were also observed which suggest that the sympathetic system, independently of the cerebrospinal system, is itself possessed of regulative powers. The authors consider the most important outcome of their experiments to be the proof that in the higher animals the principal vital processes are decentralized. [And there can be little doubt that the fashion of distinguishing as a "center" every area of gray matter the experimental stimulation of which gives rise to any recognizable reaction, however diffuse or vague, has tended to obscure our conception of the nervous system as a coordinated *system*, and not a mere loose aggregate of centers and paths.]

Homolateral Pyramidal Fibers.—Dejerine and Thomas [1] have demonstrated, as they believe for the first time in man, by an exhaustive histologic study of 7 cases of complete degeneration of the pyramidal tract, the existence of fibers which pass down from the pyramid to the lateral pyramidal tract of same side. [These fibers are of great interest, as their existence affords an explanation of the well-known clinical fact that associated bilateral muscles escape in hemiplegia.]

Reflex Action.—Pándi [2] enters a plausible plea in favor of the view that under normal conditions all reflex phenomena are essentially cortical. [Although his explanation, on this theory, of some of the clinical and experimental facts on which he bases his argument seems occasionally to be somewhat forced, it cannot be denied that physiologists, and even physicians, have often been too ready to apply phenomena seen in the decapitated frog to the circumstances of the intact human organism.] And such facts as the disappearance of the patellar reflex after pathologic lesions high up in the cord (Bastian), and its marked impairment after high section of the cord in dogs (Gad and Flatau [3]), are not easily reconciled with the ordinary doctrine.

According to Burdon Sanderson,[4] who has studied the electric changes that occur in the reflex spasm of strychnin-poisoning, the spasm is not, as has been supposed, a tetanus, but a series of brief continuous contractions.

Brain.—V. Monakow [5] has continued his exhaustive study of the 'tween

[1] Arch. de Phys., Apr., 1896, p. 277.
[2] Pflüger's Arch., Bd. lxi. p. 465.
[3] Neurolog. Centralbl., 1896, No. 4.
[4] Jour. of Phys., Sept. 5, 1895, p. xxxv.
[5] Arch. f. Psych., xxvii. p. 386.

brain (the region of the third ventricle) by the aid of carefully-selected pathologic material. He believes that in man, as in animals, each of the nuclei of the optic thalamus is connected with a definite region of the cerebral cortex in such a way that destruction of the cortical area leads to degeneration of the corresponding nucleus. Physiologically, some, at any rate, of the nuclei of the thalamus are to be considered as stations through which regulative centrifugal impulses are handed on to certain areas of the cortex. Castellino[1] concludes, from experiments on animals, that it is the motor cortical centers with which the thalami are specially connected, and that they have to do with the so-called muscular sense. [But it seems, to say the least of it, a somewhat crude and unphilosophical mode of expression to speak of the thalami as "the organs with which we judge the distance of surrounding objects."]

Vitzou[2] makes the announcement that a **regeneration of nerve-cells** has been observed by him in a monkey whose occipital lobes had been removed. [In view of the almost universal belief that nerve-cells are never regenerated confirmation will be eagerly awaited.]

H. Munk[3] has endeavored to bring the **contractures** produced in monkeys after operations on the cerebral cortex into relation with the contractures observed in pathologic cases in man. He distinguishes two groups of contractures—one in which the cause lies in a more or less permanent excitation of the related cortical areas when they have been incompletely removed, and another seen only after total extirpation of the areas. The first corresponds to the primary, and the second to the paralytic or secondary, contractures in man.

Rethi[4] and Carpenter[5] have studied the topography of the "chewing center" in the rabbit, and Ott[6] has localized (in the cat) a detrusor center for the bladder in the cerebral peduncles.

Trophic Nerves.—Krause,[7] from the results of excision of the Gasserian ganglion and the portion of the trigeminus lying central to it, comes to the conclusion that the so-called trophic influence of the nerve does not exist. W. A. Turner[8] describes experiments performed by Ferrier and himself which have led to a similar result. [And in our opinion the matter is definitely settled in this sense.] Krause found that sensation (touch, temperature, etc.) is after a time partially restored in the region supplied by the nerve.

Barker[9] has made a careful study of a remarkable circumscribed unilateral sensory paralysis (in himself), due perhaps to the pressure of a cervical rib.

The Sympathetic.—Langley[10] continues his observations in this field, which he may almost be said to have made his own. He finds evidence that the nerve-fibers in the cervical sympathetic regenerate after section. Not only so, but the fibers from each spinal nerve-root make junction with their proper

nerve-cells in the superior cervical ganglion; *e. g.* the fibers that enter the cervical sympathetic from the fourth thoracic nerve pick out the nerve-cells supplying the blood-vessels and hairs, and by no chance unite with nerve-cells sending fibers to the pupil. Langley and Anderson[1] have investigated in great detail the innervation of the pelvic and adjoining viscera. Huber[2] has studied by Golgi's method the innervation of the submaxillary and sublingual glands, and has confirmed the results of Langley and Berkley.

THE SENSES.

Hearing.—Strehl,[3] in a sort of physiologic *causerie* containing the results of experiments by 5 observers, produces evidence that pigeons do not hear after extirpation of both membranous labyrinths, and that the apparent reaction to sounds is to be attributed to the stimulation of tactile nerve-endings in the skin. Wundt,[4] on the other hand, defends the original view of Ewald, that the pigeons actually hear, against the attack of Bernstein,[5] although he finds the range of audible sounds narrower than in the normal bird. Wundt lays stress upon the observation that much more violent, but noiseless, vibrations of the air set up by bellows caused no reaction. [But to this it is possible to reply that it may be only periodic vibrations, and perhaps even periodic vibrations of a certain range of frequency, which are fitted to stimulate the hypothetical tactile end-organs.] And Strehl has actually shown that it is easy to cause tactile sensations in man by musical sounds; while Kreidl[6] comes to the conclusion that goldfish, though deaf to musical sounds, react, through a special cutaneous sense, to loud noises.

Equilibration.—Ewald[7] has made the curious observation that the labyrinth (in rabbits) influences the course of rigor mortis in the striped muscles. Rigor does not come on so soon on the side on which the labyrinth has been removed. While putting forth no theory in explanation of this remarkable fact, he points to it as in favor of his view that the labyrinth exercises a constant influence on all striated muscles.

Strehl,[8] while admitting that in certain animals (birds and, perhaps to a less extent, fishes) the labyrinth has to do with orientation, concludes from observations on deaf-mutes, in opposition to Breuer and Kreidl, that any such function which it may possess in man is of extremely little importance. The cause of galvanic vertigo he finds [and, in our opinion, rightly] not in any action of the current on the labyrinth, but in its action on some portion of the brain.

V. Bechterew,[9] in an investigation which crosses the border-line between physiology and psychology, has been led to the belief that the impressions received by the cerebral organs of equilibration from the skin and muscles,

[9] Arch. f. (Anat. u.) Phys., Mar. 26, 1896, p. 105.

and which underlie the sensations that acquaint us with the position of the limbs, etc., are the chief foundations of our conceptions of space.

Sight.—Einthoven[1] has determined the cardinal points of the eye for light of various wave-lengths. E. Müller[2] has confirmed the remarkable observations of Wolff, that after extraction of the lens in triton larvæ a new lens is formed from the iris epithelium.

Schenck and Fuss[3] show [conclusively, we think] that a phenomenon observed by Dogiel (constriction of the *opposite* pupil on stimulation of the cervical sympathetic) is only an illustration of the well-known fact that when the amount of light falling on one retina is increased the pupil of the other eye contracts.

Retina.—Weinland[4] has attempted, for the first time, to form a theory of vision which takes account of the newer histological discoveries. The details cannot be reported here, and it must suffice to say that he considers the sole visual material to be contained in the pigmented epithelium. By the action of light the epithelial cells alter their volume and so press upon the cones. In this way impulses are set up in the optic nerve.

Color-blindness.—V. Kries[5] in an interesting study of 20 cases of congenital partial color-blindness brings forward strong evidence that the red-green blind can be divided, as regards the comparison of red (lithium) and orange (sodium) light, into two sharply-separated groups—a result which is emphatically in favor of the Young-Helmholtz theory and against the theory of Hering. Peddie[6] reports a remarkable case of color-blindness in which there is, strictly speaking, blindness to all colors except red. Yet the case is not one of monochromasy, but of dichromasy, for all the tests show that there is a neutral point in the yellow portion of the spectrum, and that the colorless light of the green and blue portions is complementary to the red.

Röntgen Rays.—Axenfeld[7] makes the announcement [confirmation of which will be awaited with interest] that the Röntgen rays appear to be perceived by insects. [In the mean time, we believe that the facts, so far as reported, will hardly permit us to substitute, as the author does, "seen" for "perceived."]

Temperature Sensations.—Kiesow[8] finds that the "heat" and "cold" points of Blix, etc., once fixed, remain constant for 4 weeks and more. The "heat" points react to all stimuli, including a cold object, with a specific sensation of heat, but the greater number of the "cold" points also give a sensation of heat when touched with a warm object.

MEDICAL JURISPRUDENCE, HYGIENE, AND CLINICAL CHEMISTRY.

By HENRY LEFFMANN, M. D.,
OF PHILADELPHIA.

Entomology in Medical Jurisprudence.—The insects found on buried corpses are not of very numerous varieties, especially in the case of a very young body, whose tissues decompose rapidly. Mégnin has shown that the mortuary insects differ on bodies *buried* at different times, and that they are not the same as those found on dead bodies in the open air. He has recognized 8 species, which succeed each other in regular order and with a rapidity which depends on the condition of the medium and on atmospheric influences. A fetus buried about 1 month was examined by Dr. Mingaud[1] of Nîmes. The weather had been dry and hot, and decomposition had been active, yet he was able to fix accurately the date of the burial of the body by identifying with the microscope certain species of insects found upon the body. This development of entomology offers to medical jurisprudence an entirely new method of determining dates of death and burial.

Damages for Malpractice.—Sharp[2] reports that suit having been brought in West Virginia against two physicians for causing the death of a woman through an abortion and subsequent celiotomy for the removal of an ovarian cyst, the court held that the operations in question were "personal transactions," and that "the defendants could not testify as to anything said by them or done by them or others in her (the dead woman's) presence, or as to the condition of the patient as they found it, or anything occurring when she was present." Death having sealed the lips of one party to the transaction, it was held that the law should seal the lips of the other parties. Such a decision leaves the physician and surgeon absolutely unprotected. The jury disagreed.

Consent of the Widow necessary to Authorize an Autopsy on the Body of her Deceased Husband.—"A surviving wife is entitled to the possession of the body of her deceased husband in the same condition as when death occurred for the purpose of giving it proper care and burial, and she may sue for damages a physician or other person who, without her consent, unlawfully or wantonly dissects or mutilates the body before burial" (Foley *vs.* D., 37, N. Y. S. 471, 1896).[3]

The Law of Infanticide.—Glaister[4] says the status of jurisprudence

[1] Jour. de Méd. de Paris, Feb. 23, 1896. [2] Jour. Am. Med. Assoc., June 6, 1896.
[3] Internat. Med. Mag., May, 1896.
[4] Edinb. Med. Jour., July, 1895, quoted in Boston M. and S. Jour., Feb. 20, 1896.

relating to infanticide is such that a woman who kills her offspring before delivery is complete may escape the law. The civil rights of an unborn heir are recognized when its prospective inheritance is concerned, but its mother may murder it during parturition, provided she does not conceal her pregnancy or the child's birth. The burden of proving that the child was not born dead, or that it was killed after it had been wholly born, rests upon the State, and the accused gets the benefit of the doubt. More effectual legislation in this regard is needed. Glaister thinks that evidence of violence on an infant's body, whether the child were dead or not when injured, should entail severe punishment on the perpetrator, and that in cases in which the child has breathed at all, whether fully born or not, there should be the presumption of a "live birth" allowed.

Detection of Blood-stains in Medico-legal Cases.—Iron prevents the formation of hemin crystals. Hydrogen peroxid, added to a slight scraping of the suspected blood-substance previously softened by feebly alkaline water, causes an evolution of oxygen if blood be present.[1]

Hypnotic Confessions.—Maggie B——, having confessed to false testimony in a murder case, and having accused herself of the deed, was hypnotized by Dr. Callen. The woman was dying of consumption. Under hypnosis she stated that her first statements were true, and that she did not commit the murder, having confessed to it to shield her son, whom she feared was implicated. "Such attempts are scientifically unjustifiable, since the influence of leading questions producing suggestion cannot be excluded."[2]

The Red Blood-corpuscle in Legal Medicine.—According to White,[3] reliable measurement of blood-corpuscles from blood-stains can generally be made. Should error occur from an imperfect restoration of the form of the hemocytes, the tendency is to make human blood resemble that of lower animals, and not *vice versa*. Mammalian blood can be identified, and the blood of the ox, pig, horse, sheep, and goat can be excluded. Though human blood cannot be distinguished from that of certain other mammals, the confusion of possibilities may be much modified by a good microscopist.

Homicide without External Marks of Violence.—Presbrey[4] reports that a man was found dead in bed with no external marks of violence on his body, with pupils of medium size and equal, and a history of excessive drinking during the previous day and night. His death was attributed to alcohol-poisoning, and the body was buried without an autopsy. Three days later, as there was newly-developed evidence that the deceased had been struck on the head with a fence-paling during a drunken quarrel, the body was exhumed. An autopsy revealed an intracranial clot formed apparently by the laceration of a small vessel. The blow had not felled the man; he had not lost consciousness, but walked home, and was found apparently in a drunken

[1] Med. World, Nov., 1895, quoted in Yale Med. Jour., Apr., 1896.
[2] Alienist and Neurol., Oct., 1895.
[3] Med.-Leg. Jour., Mar., 1895, p. 419, quoted in Boston M. and S. Jour., Feb. 20, 1896.
[4] Boston M. and S. Jour., Apr. 2, 1896.

sleep in an outhouse. He was put to bed (probably in a state of coma) and left to sleep off his drunkenness. He was found dead in the morning, as stated. This was a case in which there was no abrasion, swelling, or any external mark to suggest possible intracranial injury, though death had actually been caused by the unsuspected injury.

The Stomach-test in Murder Trials.—Liebmann[1] says the reliability of tests applied to the solid contents of the stomach with a view to determining the time at which death took place in cases in which the time of the last meal is known depends upon an accurate knowledge of—1. The comparative digestibility of different foods; 2. The amount of food taken, inasmuch as an overloaded stomach digests more slowly than a stomach less distended: 3. The varying degrees of acidity and peptogenic power found in healthy stomachs; 4. The occurrence of psychical influences (fright, grief, joy, etc.) during digestion.

Poison in Expired Air.—Livierato's[2] experiments with the condensed aqueous vapor of the breath of persons with and without disease of the respiratory tract, injected into rabbits, show a toxic action in the liquid obtained from the diseased persons, but no such action in the liquid obtained from healthy persons. The results were the same when the liquid was sterilized.

The Limerick Food-poisoning Cases.—Cameron[3] reports 70 inmates of a boarding-school seriously affected by ptomain-poison, attributed to eating a custard made from eggs which were described as "not quite fresh;" 3 women died from the effects, one 13 days after the seizure.

Lead-poisoning from Public Water-supplies.—Whitelegge[4] says the projectors of every new water-scheme should be obliged to demonstrate whether or not the supply under consideration embodies a plumbosolvent water. Lead-poisoning is a subtle disease, and may do irreparable damage before it is suspected. No water should be used for drinking which contains even a trace of lead. In a small Massachusetts town of scarcely 1500 inhabitants 25 persons exhibited various degrees of lead-poisoning traceable to the public water-supply. Investigation showed in nearly all cases that the water which stood all night in the lead pipes had not been carefully withdrawn and rejected. Lead pipes were used in this town in connecting the houses with the street-mains. The water of this town contained in several instances as much as $\frac{1}{2}$ gr. per gallon, and lead was found in the urine of all patients examined.

The Pollution and Cleansing of Rivers.—Following certain investigations as to the pollution of the river Oker in the Hartz Mountains, Blasius and Beckert[5] conclude that rivers are polluted by domestic fouled water and

[1] Am. Med.-Surg. Bull., Aug. 1, 1895, quoted in Boston M. and S. Jour, 1895, cxxxii. No. 9, p. 207.

[2] Arch. ital. di. Biol., 1895, p. 279, quoted in Am. Jour. Med. Sci., Jan., 1896.

[3] Brit. Med. Jour., July 20, 1895.

[4] Public Health, London, 1895, quoted in Boston M. and S. Jour., Mar. 5, 1896.

[5] Deutsch. Vierteljahrs. f. Gesundheit., 1895, p. 337, quoted in Boston M. and S. Jour. Mar. 5, 1896.

by factory waste; that the self-purifying powers of rivers depend (*a*) upon the extent of the dilution to which the polluting matters are subjected, (*b*) the access of atmospheric air, (*c*) the temperature, and (*d*) exposure to sunlight and daylight; that the waste water from houses and industrial establishments should be irrigated; that gravel and sand filters are best adapted to filter river-water on a large scale.

The Disinfecting Power of Soap-solution.—Jolles[1] made a sterilized solution from soap with 67.44% of fatty acids, 10.40% of total alkali, and 6.041% of free alkali, and this was incorporated with meat-juice-peptone bouillon containing the germs of typhoid fever and bacillus coli communis. Ten sets of test-solutions were observed at different times and temperatures. The experimenter found the soap solution had better disinfecting properties at low temperatures (4° C. to 8° C.) than at ordinary temperatures. Between 18° C. and 30° C. there is little difference in the antiseptic power of the solution. Rags treated with a 1% soap solution showed injury to the contained germs in 15 minutes, while with a 6% soap solution all germs on the rags were destroyed. Soap therefore furnishes a powerful and safe disinfecting agent for certain disease-germs.

Contents of the Healthy Stomach.—Gillespie[2] says: Free hydrochloric acid does not appear in the stomach till from ½ to 3 hours after a meal. During digestion it is combined with proteid, and is less antiseptic than free acid. After a meal there is from 0.09 to 0.27% of free hydrochloric acid in the stomach, according to the food taken. During digestion albumin increases, albumoses remain stationary, while peptone and the inorganic salts, especially chlorids, diminish.

The Hydrochloric Acid of the Stomach.—Hydrochloric acid is the only normal acid in the stomach, and is derived from the chlorids of the blood. It is not the free acid that is the active digestive agent, but the albumin compounds of it. The free acid appears only after digestion is finished. The formation of acid albuminate is necessary to the action of pepsin on albumin; the peptonizing of albumin is quite a secondary function of the stomach.[3]

Cholera-bacilli and Uncooked Milk.—Contrary to the conclusion of Hesse, who claimed that uncooked milk had the property of killing the cholera-germ in 12 hours, Basenau[4] says that up to the point of coagulation these bacilli in milk increase in number, and continue active even after the milk is soured, and that milk is by no means a prophylactic against cholera.

Modified Milk and Sterile Milk.—Leeds[5] says cow casein and human casein differ in chemic composition, in their relations to the mineral substances in the two fluids, and in their behavior with chemic reagents. With acetic acid cow's milk yields a dense casein precipitate, while woman's milk pre-

[1] Zeit. f. Hyg., 1895, p. 130, quoted in Boston M. and S. Jour., Feb. 27, 1896.
[2] Rep. of Lab. R. C. P., Edin., 1894; Jour. Chem. Soc., 1895.
[3] Am. Med.-Surg. Bull., Sept. 15, 1895.
[4] Arch. d. Hyg., xxiii. p. 170, quoted in Am. Jour. Med. Sci., Jan., 1896.
[5] Am. Jour. Med. Sci., Sept., 1895.

cipitates but a small fraction of its casein. This fact is apparent even when there has been an aqueous dilution until the percentage of casein is the same in both milks. The inability to precipitate the casein of woman's milk by acetic acid makes it difficult to determine how much fat is separated when casein is precipitated. Casein and fat do not stand in any fixed ratio in milk. The assumed ratio in cow's milk is 1 to 1.16. Leeds found it to be 1 to 1.22, and in woman's milk 1 to 3. Therefore the coagulum of cow's milk would contain only about $\frac{1}{3}$ the amount of fat found in the coagulum of woman's milk. The general practice is therefore to add fat to cow's milk intended for infant-feeding till the ratio stands 1.22 of casein to 3 of fat. Yet experiment shows that in the laboratory the presence of the excess of fat added to cow's milk makes no change in the inherent nature of the particles composing the clots themselves. The surplus fat serves as an attenuant, and the same effect is produced on the coagulum by adding gum, sugar, dextrin, extract of barley or oatmeal, etc. The latter bodies are, however, foreign and abnormal to natural infant food, while butter-fat with lactalbumin and lactose are natural attenuants of the clot. A deficiency in lactalbumin is not satisfactorily removed by adding strained egg-albumin. Lactose is useful in attenuating the clot of cow's milk. Leeds recommends also globules of butter-fat and soluble proteids (noncoagulable by acids). The lactose and fat of cow's and woman's milk are practically identical in composition. The "humanized" milk made by diluting cow's milk $\frac{1}{2}$, and adding $\frac{1}{8}$ of the total of average cream contains, according to Leeds, 1.74 of casein and 0.44 of albumin, while human milk contains 1.35 of casein and 0.65 of albumin. Albumin has been added to overcome the deficit, but the excess of casein persists. This insoluble proteid may be diminished by "an incipient and very partial peptonization of the casein," which process has the advantage of being at the same time a sterilization. To sterilize milk it is not necessary to heat it above 100° C. Spores requiring so high a temperature to destroy them are rarely present. Leeds found that 70° C. continued for a $\frac{1}{2}$ hour usually destroyed all bacteria in milk. Infants fed upon sterilized milk lose much more nitrogen in the feces than those fed on raw milk. It is possible that the unfavorable results noted by careful observers in feeding infants on sterilized milk, as compared with breast milk, are due to the relation of the casein of cow's milk as compared with that of woman's milk, as already noted.

Microorganisms in Milk.—Freeman [1] says the milk of a healthy cow as it comes from the udder is practically sterile, yet the milk delivered to the consumer in large cities is contaminated with many microorganisms. As many as 15,000,000 bacteria have been found in a single drop of city milk. Most of these are nonpathogenic, and may be classed as "dirt." Milk drawn and handled by clean, rapid methods contains only $\frac{1}{1000}$ as many bacteria. These germs cause the milk to sour, and some of them cause diarrhea in children. The loose dairy-methods which favor the entrance of so many microorganisms multiply the chances of introducing pathogenic bacteria. Disease-

[1] Am. Med.-Surg. Bull., Jan. 25, 1896.

germs may enter in milk from the udder or tissues of the cow. Milk is a good culture-medium. If contaminated by specific disease-germs, it may readily give rise to an epidemic. The bacillus tuberculosis is readily inoculated through milk; 7% of all cattle in New York State are tubercular, if the tuberculin-test is reliable. Ernst, Bang, and others have shown that general tuberculosis in cows, without any disease of the udder, may engender tubercle-bacilli in the milk of those cows. The mixing of milk from different cows increases the chance of tubercular infection. Tuberculosis in cows is very common, but hard to detect by ordinary physical examination. Freeman recommends the tuberculin test as delicate and harmless to sound cows. He considers it our best protection against the tubercular contamination of milk, but he urges also better dairy inspection and control, with a view to diminishing the chance of infecting milk with pathogenic microorganisms of any kind.

Effects of Definitely-related Chemic Compounds on Animals.[1]—If hydroxyl be substituted for hydrogen in phenol, the physiological action of the drug is intensified, subject, however, to a certain influence due to position isomerism. The reducing phenols are the most active therapeutic agents. Alkyl radicles substituted for hydrogen modify the physiologic action, while nitrogroups both change and intensify it. The presence of one nitrogroup affects the circulation mainly, the nervous system hardly at all, the action increasing as we pass from the orthocompounds to the paracompounds. The results are intensified as more nitrogroups are substituted. The nitrobenzenes show a similar but less powerful action. Nitranilins stimulate the vagi peripherally and alter the hemoglobin of blood. Anilin itself affects the nervous system mainly, but the nitranilins affect it very little. Methyl groups substituted in anilin (toluidins) resemble therapeutically the nitranilins.

Some Chemic Properties of Certain Alkaloids.[2]—The effect of decomposing animal matter on strychnin is to render it in time irresponsive to the color and certain other chemic tests, though its bitter taste and therapeutic action are still preserved. Ordinary toxic doses of morphin and strychnin indicate that the absorbed portions of the alkaloids found in the tissues lose the property of crystallizing, but in cases where very large amounts of these drugs are taken they may be recovered in the crystalline state, as considerable portions of the dose diffuse by simple exosmosis.

The Hygiene of the Kidney.—Simes[3] says unhealthy kidneys may beget an unhealthy heart, lungs, brain, or nervous system. In watching the kidneys make allowance for diet, liquids taken, exercise, and perspiration. No reliable conclusion can be based on an examination of anything but the total urine voided in 24 hours. Most people eat too much, and drink too little water. The milk diet owes some of its benefits to the normal presence of the water in this fluid. Food should be masticated, however, and not

simply *washed down* without a proper mixture of saliva. The good results of a sojourn at a mineral spring are often due to flushing of the system with water. An excess of water, on the other hand, overworks the kidneys. Warm clothing prevents renal congestion. Judicious bathing is useful.

Uric-acid Gravel.—Harley[1] says the theory that uric acid is a proteid waste-product incompletely oxidized, and on the way to become urea, would suggest that uric acid in excess should occur in the urine of all persons suffering from diseases where imperfect oxidation exists; but this is not the case. Birds, moreover, excrete uric acid normally, and uric acid given by the mouth does not appear in human urine as an excess unless the blood be kept alkaline. Nuclein, and not the general proteids, has been suggested as the antecedent of uric acid. Horbaczewski made some successful experiments in support of this theory. Nuclein by the mouth increases uric-acid elimination (Horbaczewski) or (according to Stadthagen) urea. These contradictory opinions have yet to be investigated. Marès found a double quantity of uric acid in urine excreted after meals, as compared with the urine of fasting periods, animal foods being most favorable to the rise in uric acid. This has been attributed to the increase of leukocytes after nitrogenous feeding and the consequent increase of nuclein. Leukocythemia is associated with a large increase of uric-acid elimination, attributed to the excess of nuclein derived from the increased number of leukocytes. Other diseases, such as pneumonia, show a similar phenomenon. The leukocytosis following the administration of pilocarpin and phosphorus are associated with an increase of uric acid in the urine. Alcohol also increases uric-acid excretion.

Causes of Uric-acid Deposits.—Ritter[2] says that why uric-acid deposits in urine occur not only in pathologic cases, but in many healthy individuals, and in instances in which the degree of urinary concentration does not seem to warrant their insolubility, is a fact not yet adequately explained. The brickdust deposit, according to Bence-Jones, is a mixture of which a portion is the excess of uric acid unsatisfied by the alkalies present. Zemer believed that the precipitation of the urates depends solely on the relation of the disodic phosphates to the urates. Ritter, by experiment, found—1. That when only monosodic phosphate and the acid urate salts are present, the crystalline urates are deposited, unless the degree of concentration is so great that the salts do not act on one another at all; 2. That those urates formed by the union of monosodic phosphate and acid sodium urate are held in solution by disodium phosphate; 3. When disodium phosphate is present with acid sodium urate in concentrated solutions the typical crystals of acid-sodium urate are formed either in alkaline or neutral solutions. Ritter thinks the tophi of gout are formed in the same way. The appearance of sediments of urates denotes an action on the part of the phosphates, and the crystalline urates or brickdust deposit depends either on a total absence or a relatively insufficient quantity of disodic phosphate.

Rare Urinary Calculi.—Horbaczewski[1] reports 2 rare forms of calculus, 1 containing free fatty acids, fats, and soluble soaps of calcium and magnesium, besides other unusual constituents, and the other containing 95% of organic matter, almost all of which was cholesterol.

The Measure of Acidity or Alkalinity in Organic or Other Fluids.—Nichols[2] proposes a uniform system to express the results of volumetric acidimetry and alkalimetry. The natural standard being the normal solution (alkaline or acid), it is fixed at the number 1. All other degrees of acidity and alkalinity are indicated by numbers relative to this unit, which is expressed as *N*. When the acidity of the fluid is $\frac{22}{1000}$ of a normal acid solution, it is expressed as .022 *N*. A fluid of which 10 c.c. is neutralized by 4.5 c.c. of decinormal acid has an alkalinity of .045 *N*. A double normal solution would be 2 *N*; a decinormal, .1 *N* or $\frac{N}{10}$. Nichols uses plus (+) as a sign for acids and minus (—) for alkalies. The normal factors as given facilitate computation of percentages by weight of substances present.

Notes on Urine Analysis.—The addition of solids to urine to clarify it is not recommended by Smith.[3] In the nitric-acid test for albumin a mere cloudiness above the contact-zone does not signify albumin. The mucus always present in urine yields *nucleoalbumin*, which cannot be perfectly precipitated by acetic acid, and is a source of error in inferences. With the ferrocyanid test nucleoalbumin (from mucus) gives a mere opacity, while true albumin gives a finely flocculent precipitate. Alimentation is a factor in the results of all quantitative estimations. Slight variations in the amount of uric acid excreted are within the limits of a healthy condition. The ratio of urea to uric acid in an experimental case (normal) was 1 : 54; in a neurasthenic case, 1 : 37.6. The use of alcohol increases uric-acid excretion.

The Elimination of Arsenic and its Detection in the Urine.—Mann[4] says arsenic in as small amounts as 1 part to 200,000 of water can be detected in the urine by Reinsch's test any time short of 11 days after its absorption. To apply the test accurately evaporate 12 to 16 oz. of urine to $\frac{1}{4}$ its volume, and boil for 15 minutes with the reagents before accepting a negative result. Prove the HCl and copper-foil used to be free of arsenic, and carry the test to the sublimation of the arsenic and its crystallization as As_2O_3.

Oxaluria and the Excretion of Oxalic Acid in Urine.—Dunlop[5] says alcohol added to the urine precipitates crystals of calcium oxalate (Reach's method). The centrifuge facilitates the deposit of the crystals. Oxalic acid is regarded by Dunlop as a normal and constant constituent of human urine. The salts of this acid precipitate in some urines, due mainly to the presence of an excess of oxalic acid. Food-stuffs containing oxalic acid are the source of the acid in the urine. "Oxaluria has no pathologic entity;" its occurrence has no diagnostic value.

Urinary Pigments.—According to Garod,[1] urospectrin, a pigment similar to hematoporphyrin, found in normal urine, is extracted by shaking the urine with acetic ether. The residue from this solution after evaporation is soluble in ether, especially in the dark. The ether extract contains the new pigment, urospectrin, associated with the chromogen of urobilin. The latter decomposes in the light, and the urobilin is removed by shaking with water. Garod says that hematoporphyrin is a scanty but constant ingredient of normal urine. He extracts it by adding to 100 c.cm. of urine 20 c.cm. of a 10% solution of sodium hydroxid. This precipitates the phosphates, which are washed with water and redissolved in rectified spirit. After acidulation with hydrochloric acid the solution shows bands of acid hematoporphyrin. The alkaline pigment may be obtained by adding ammonia to precipitate the phosphates, acetic acid to redissolve them, and extracting the pigment with chloroform. Studensky removes urobilin from the urine by taking 20 c.cm. of urine and treating it with 1 : 10 solution of saturated copper sulphate solution, then saturating with crystallized ammonium sulphate, and adding 10 c.cm. of chloroform. The mixture is shaken some minutes, and the copper-red layer of the chloroform solution is removed by a separating funnel. It is then compared with a standard urobilin solution in chloroform. The standard solutions are kept as long as 2 months by covering the surface with a layer of saturated ammonium sulphate, closing the vessel and placing it in the dark.

Bile-pigment in Urine.—After a comparison of 20 tests, Jolles[2] recommends Rosenbach's modification of Gmelin's test as being as delicate as the original, requiring only 5% of bile to produce a reaction. Rosin's and Huppert's tests each react with 20% of bile.

Chloroform in the Urine or Other Liquids.[3]—The test consists in passing a current of pure hydrogen through the suspected liquid, and burning the gas at its exit. A fine brass gauze thrust into the flame assumes a bluish-white color. The products of this combustion are removed from the wire gauze and placed in a solution of ammonium hydroxid (ammonia). A blue color appears, and the presence of free chlorin is detected. Urine containing chloroform reduces the solutions of Fehling and Trömmer. Vitali's results concur with those of Kast, von Mering, and Zeller, but are opposed to those of Bréaudet.

A Delicate Test for Albumin.—Adolf Jolles,[4] on the grounds of the delicacy and effectiveness of the reagent, independent of the composition of the urine, recommends the following solution: Mercuric chlorid, 10; succinic acid, 20; sodium chlorid, 10; water, 500. This reagent is more sensitive than potassium ferrocyanid; it will detect albumin in the proportion of 1 : 120,000.

[4] Hoppe-Seyler's Zeit. f. phys. Chem., 1895, xxi. No. 4, p. 306: Am. Med.-Surg. Bull., June 6, 1896.

Errors in Spiegler's Test for Albumin.—Sharp[1] substitutes glycerol for sugar in Spiegler's test, which was, originally, mercuric chlorid 8 parts, tartaric acid 4, sugar 20, and distilled water 200. The sugar and glycerol are added for the purpose of raising the density of the mixture and allowing the urine to float. In the absence of, or in case of a deficiency of, chlorids, the test does not act with weak albumin solutions, or acts very slowly. This is to be remembered in testing urine secreted during diseases which diminish the amount of chlorid in urine. On the other hand, an excess of chlorids or of tartaric acid hinders the precipitation of albumin by mercuric chlorid. Sharp inclines to favor the old nitric-acid test for albumin as less open to possible error and objections than Spiegler's or other tests, such as picric or trichloracetic acid.

Albuminuria.—Although globulin is associated with albumin in the urine, the amount is so variable that it is of no use in determining the variety of kidney in any given case. In the investigation of Boyd[2] the total proteids were estimated by boiling the urine, estimating the proteids, and removing the globulin by half-saturation with ammonium sulphate. The globulin was estimated by the difference.

Peptonuria.—The proteids present in cases of so-called peptonuria are albumoses, not true peptones. The presence of these bodies is an almost invariable symptom of croupous pneumonia and purulent meningitis, sometimes of articular rheumatism, and occasionally of leukemia. Robitschek says peptonuria occurs often in phosphorus-poisoning and during suppuration. L. Sior[3] notes the absence of these bodies in the urine of children.

Nucleoalbumin in the Urine.—Nucleoalbumin[4] may occur in the urine in rare cases where there is extensive disintegration of renal epithelium, but it is usually absent from the secretion.

The Value of the Usual Tests for Sugar in the Urine.—Jolles[5] says a high specific gravity is not a constant indication of sugar; that sugar is not a normal element in the urine; and that small amounts of sugar do not affect its density much. The results obtained from Trömmer's and Worm-Müller's tests are often confusing, and as much as 0.24% may escape them. Urines containing less than 0.3% do not react well with Nylander's test. Out of 200 specimens examined with the polarimeter and the Fehling-Wendriner quantitative method, 66 gave accurate results. Jolles recommends the phenylhydrazin test for doubtful cases. He boils the test-tube containing the urine and reagents in the water-bath for an hour, and then lets it stand for from 12 to 14 hours. Hoppe-Seyler's test with alpha-nitrophenylpropionic acid is rated in delicacy at about 0.4%.

[5] Aerzt. Rundsch., No. 3, 1895, p. 40.

The Value of the Phenylhydrazin Test for Sugar.—The urine of 50 persons with no glycosuria was tested by Williamson[1] by boiling with phenylhydrazin hydrochlorid and sodium acetate, and examining in the cold some time later, with a uniformly negative result. In cases in which sugar was present bright sulphur-yellow crystals of phenylglucosazone were found in 6 or 8 hours or less. Crystals of glycuronic acid, similar to the phenylglucosazone, occur in rare cases, but generally on account of some drug taken, in which case discontinuance of the medicine causes the glycuronic acid to disappear. Williamson thinks the chance of error in this test very slight. He commends it for sensitiveness before Fehling's and the fermentation test, and as giving a reaction in dilute urine with .015% of sugar. Phenyl-hydrazin is too delicate in its reactions for use when prolonged boiling and the water-bath are used. It is an excellent negative test, and may be used to confirm a result which appears slightly dubious with Fehling's. Glycuronic acid and pentose are the only substances in the urine which may be confused with the various sugars by the phenylhydrazin test, while there are many sources of reduction besides sugar with Fehling's solution.

The Verification of Sugar-testing in the Urine.—To remove normal ingredients of the urine which tend to mislead the observer in delicate sugar-tests (such substances as uric acid, kreatinin, etc.), Dr. Roberts[2] recommends filtering through animal charcoal the urine to be examined. The filtrate, having no color, shows Fehling's reaction readily, and the urine is less dense. For delicate tests Fehling's process is recommended in preference to the fermentation process.

A Delicate Method of Estimating Sugar in Urine.—The uric acids, xanthin, hypoxanthin, phosphates, etc., are precipitated by boiling 8 c.c. of the urine with 5 c.c. of the copper sulphate solution, as used in Fehling's test. On cooling add 1 to 2 c.c. of a saturated sodium acetate solution. Filter and add 5 c.c. of alkaline tartrate solution of the usual strength, and boil the mixture 15 to 20 seconds. The orange-yellow cuprous oxid precipitate separates in the presence of more than 0.25% of sugar, and in the presence of less amounts on cooling. Allen[3] prefers phenylhydrazin in qualitative sugar estimations of sugar.

A New Method of Estimating Sugar in the Urine.—Elliott[4] objects to Fehling's test for saccharine urine on the ground that, as it depends wholly upon the reducing power of sugar as indicated by a copper-test solution, it lacks delicacy, and, because of the normal presence of other reducing agents in the urine, it is not an accurate method in the hands of any but very experienced workers. He claims that copper reduction will take place in Fehling's solution with normal urine which is concentrated and of high density. The following test is proposed to detect as little as one-tenth of 1% of sugar. Two solutions are prepared: No. 1 contains—Copper sulphate

[1] Med. Chron., 1895, iii. No. 5, pp. 333–341, quoted in Am. Med.-Surg. Bull., Nov. 15, 1895.

[4] N. Y. Med. Jour., July 27, 1895.

(C. P.), gr. xxvij ; glycerol, pure, fʒiij ; distilled water, fʒiss ; sodium hydroxid, ad fʒiv. No. 2 is a saturated solution of tartaric acid (C. P.) in distilled water. These solutions will keep indefinitely and are used as follows : Heat to boiling 1 dr. of No. 1 in a test-tube ; then add 2 or 3 drops of No. 2 and boil again. The urine is then added slowly, drop by drop, shaking the test-tube after each drop until reduction occurs. The presence of sugar is indicated by a yellowish or reddish (sometimes greenish-gray) precipitate of copper suboxid, which accumulates on standing. If this reaction fails to occur after 8 drops of urine have been added, there is no appreciable sugar present ; 1 drop will be followed by a reaction where sugar is present in large amount. For quantitative estimation proceed as follows : Place 133♏ of Solution No. 1 in a flask and add 6 drops of Solution No. 2, with 3 dr. of liquor ammoniæ (U. S. P.). Mix thoroughly, and add distilled water to make 2 ounces. The cuprous oxid formed is dissolved in the ammonia, giving a clear blue which completely disappears in the end-reaction. The foregoing amounts of the test-solutions represent in sugar value ¼ gr. The application of the test is the same as in Pavy's or Purdy's method.

The Picric-acid Test for Sugar.—McDonald[1] says the picric-acid test for sugar in the urine depends upon the reduction of potassium picrate, formed in the reagent solution, to picramate by the deoxidizing power of dextrose, and the appearance of the orange-red color characteristic of the picramate. He notes the complicating disturbance of the test by the presence in normal urine of kreatinin, and also the modification of the reaction which is caused by dilution.

The Estimation of Urea by Hypochlorite or Hypobromite.—Thudichum[2] regards the hypochlorite process of estimating urea as unreliable, and the hypobromite substitution as open to a like objection. The latter substance is so unstable that it has to be freshly prepared from liquid bromin and caustic soda. If the process worked perfectly, 0.1 gram of urea should yield 37.14 c.c. of N at standard conditions. Practically, this never occurs. The result varies with the concentration of the hypobromite and of the urea solutions, with the concentration of the mixture of both solutions, with the time allowed for the reaction, with the contents of the eudiometer (mercury being the best), with the apparatus used, and with the personal care of the observer. Falck showed the N evolved comes from other nitrogenous matter in the urine besides the urea, so that if only a urea determination is desired, the hypobromite process gives an excess of N, while, as it does not liberate all of N from the substances which contain it, the process will not serve to determine the total N present. Liebig's method is superior in this regard. Urea may be separated in solution from urine by treating the secretion with mercurammonium and filtering through charcoal to remove alkaloids. The filtrate is pure urea solution. Thudichum recommends Liebig's process as indicating the amounts of N present in the three principal forms, and as being generally better for clinical purposes.

[1] Lancet, Feb. 22, 1896.

[2] Med. Press, Dec. 25, 1895, p. 657.

Some Dubious Reactions for Alleged Carbohydrates in Urine.—According to Thudichum,[1] the reduction of copper acetate by dextrose requires from 12 to 60 hours for its completion. In the cold the solution of this salt is a test for dextrose, but the mixture should not be heated unless acetic acid be added also to prevent the oxidation of dextrin, which would then also reduce the copper. Copper acetate with acetic acid is Barfoed's test for dextrose. Its application is slow, and involves the danger of reoxidation of the copper by the air or decomposition of the acetate by heat. This test will, however, detect, under proper precautions, $\frac{1}{3\,2}\%$ of dextrose in solution. Worm-Müller diluted the solution used by Barfoed, till it valued 4% of the salt and 1% of acetic acid. This observer claims that "*normal urine contains a substance or several substances which reduce copper in an acid acetate solution,*" and that this substance cannot be dextrose—a conclusion which seriously impeaches the test. Müller and Hagen prefer Knapp's to Fehling's solution in testing animal fluids; Thudichum does not. Thudichum made experiments which show that this reduction in urine with Barfoed's test, not due to dextrose, is due to at least one of the alkaloids—namely, urotheobromin—or to urotheobromin and kreatinin. If the alkaloids be removed by animal charcoal and the solution be made alkaline by mercuramin, a reduction of alkaline copper tartrate (Fehling's) means the presence of dextrose.

Carbohydrates in Normal Urine.[2]—The total amount of carbohydrates (reckoned as glucose) in normal urine is 0.01%. Of glucose, the amount actually present is 0.005%, the carbohydrate residue being a dextrin-like substance (animal gum) and a third ingredient, probably isomaltose.

The Reaction of Sulfonal in Urine.—According to Lafon,[3] urine containing sulfonal tested with Fehling's gave the yellow copper suboxid precipitate in 20 cases, and slight left-handed deviation by the polariscope.

The Alkaloids of the Urine.—Thudichum[4] says that experiment shows that of the nitrogen discharged daily in the urine of a male adult, 1.8436 g. is in the shape of alkaloids, of which there are six; urotheobromin ($C_7H_8N_4O_2$) is one of these. Its compound with copper oxid, boiled with pure water, reduces the oxid steadily. A pure cupric compound is hard to obtain. The solution of all the alkaloids reduces copper acetate in acid liquid to cuprous oxid, and has a similar action on other oxidized substances.

The Clinical Import of Hypoxanthin.—According to Thudichum,[5] hypoxanthin is an alkaloid of the uric-acid group. It is usually not excreted by the urine; its presence in that secretion is always associated with albuminuria and some form of aberration of the kidneys. Copper acetate added to the urine precipitates urotheobromin and urochrome. Hypoxanthin is separated from these two compounds by dissolving the precipitate in an excess

of cold nitric acid and adding silver nitrate to the solution. The latter salt forms a compound with hypoxanthin, the new compounds being insoluble in nitric acid, while the urotheobromin products are soluble. Hypoxanthin dissolves in hot nitric acid, but crystallizes from it on cooling. The phosphomolybdic process followed by the foregoing reaction serves to isolate hypoxanthin from large volumes of renal secretion.

The Cobalt-carbonate Test for Free Acid in Gastric Juice.—The cobalt carbonate for this test was freshly prepared by Kuratkowski.[1] The reaction shows a change from rose-color to blue, due to the production of cobalt chlorid by the action of the free hydrochloric acid in gastric juice. Neither lactic acid, butyric, nor acetic peptones, nor acid sodium phosphate, yields this reaction. It is hindered by the presence of mercury or sodium chlorids, ferric chlorid, or ammonium chlorid. This reaction appears if 1 part in 10,000,000 of free hydrochloric acid be present. It is 500 times more delicate than the phloroglucol-vanillin test.

Ehrlich's "Diazo-reaction."—This reaction, Ettles[2] says, occurs occasionally in the urine of healthy persons; invariably in typhoid fever and pneumonia; generally in pleurisy; frequently in measles, peritonitis, suppurative inflammation, erysipelas, phthisis. Occasionally it is present in rachitis and diabetes mellitus, but seems to be absent in malignant and chronic non-tuberculous lesions. Rötheln may be distinguished from measles by its absence. Suspicions of typhoid are confirmed by its presence, and tuberculous phthisis is differentiated from chronic pulmonary diseases.

Accumulation, fecal, 302.
Acephalic omphalosite, 467.
Acetanilid, amblyopia from, 931; boric, 657; as a dressing for wounds, 657; -gauze, 657; -glycerol, 657; -oil, 657; poisoning by, 1101; in puerperal hyperpyrexia, 540; in purulent otitis media, 974; -vaselin, 657.
Acetone in the urine, 187.
Acetonuria, 187; after anesthesia, 252; in fetal death, 466.
Achenbach on horny growths of the lid, 907.
Achillo-bursitis anterior, 888.
Achillodynia, 888.
Achylia gastrica, 161.
Acid, free, in the gastric juice, 1196; hydrochloric, in bone-diseases, 879; nucleic, 1128; salicylic, 1137.
Acidity of fluids, 1190; of the gastric juice, 154.
Acker on cardiac anomalies, 786.
Acne, curet in, 1083; etiology, 1081; of the face, massage in, 1082; rosacea, alcohol in, 1082; topical treatment of, 1083.
Aconitin in erysipelas, 50; in tic douloureux, 818.
Acoustic railroad signals, 970.
Acromegaly, 843; and gigantism, 846.
Acrosphacelus, symmetric, 1056.
Actinomycosis, 115, 1054; cutaneous, 1054; of the lacrimal sac, 910; primary, of the lung, 698; therapeutics of, 1055.
Action of alcohol on the cortical nerve-cell, 689; of pepsin, 163; of poisons on the kidney, 700; reflex, 1179.
Active immunization against cholera in man, 730.
Activity of pepsin, 154.
Acute ascending paralysis, 861; bulbar paralysis, 834; endocarditis, 123; endocarditis, gonorrheal origin, 123; exudative erythema, 1058; infectious disease of bone, 884; infectious diseases and leukemia, 677; inflammation of bone, 369; inflammation of the lingual tonsil, 1013; nephritis from shock, 798; osteomyelitis, 370; osteomyelitis of the spine, 394; otitis, mastoiditis after, 964; otitis of measles, 964; otitis media, incision in, 967; meningitis after, 964; in pneumonia, 962; purulent leptomeningitis after, 964; after removal of adenoids, 963; secondary infection, 965; septicemia from, 965; treatment, 965; in typhoid fever, 962; pancreatitis, 183; pemphigus, 1039; phthisis, 33; plastic iritis, 919; rheumatism, 69;

thyroiditis, 149; yellow atrophy of the liver, 179; in children, 783.
Adami (J. G.) on carcinoma, 627; on inflammation and fibrosis, 740; and Kirkpatrick on Madura foot-disease, 1055.
Adamkiewicz on papillitis, 933.
Adams on diphtheria, 760; on foreign bodies in the ear, 959. on pneumonia in children, 790; on pulmonary stenosis, 132.
Addison's disease, 104; experimental, in the sewer-rat, 704; suprarenal extract in, 104; thyroid extract in, 1106.
Adenitis, cervical tuberculous, 1017; suppurative, of the groin, 217.
Adenoid hypertrophy of the nasopharynx, 1010; vegetation in the nasopharynx, 968.
Adenoids, acute otitis media and, 963; in children, 1011; and incontinence, 1011; stammering due to, 1011.
Adenoma destruens, 630; malignant, of the uterus, 630; pigment, of the conjunctiva tarsi, 916; sebaceum, 1084; of the thyroid gland, 351.
Adenomyoma of the round ligament, 664.
Adenopathy, supraclavicular, in intraabdominal carcinoma, 307.
Adenoud on nystagmus, 893.
Adherent retroposed uteri, 608.
Adhesion of the placenta, 460.
Adhesions, pericardial, 122; peritoneal, 169; peritoneal, after abdominal section, 655.
Adhesol as an antiseptic, 212.
Administration of thyroid glands, 89.
Adolescent uterus, 510.
Adonis vernalis in epilepsy, 815.
Advancement, 903.
Afanasieff on infected wounds, 741.
African fever, 57.
After-effects of ether, 247; -treatment of abdominal section, 657; -treatment of gastrostomy, 269.
Age of menstruation, 586.
Aged, pulmonary tuberculosis in, 34.
Agella on fractures of the base of the skull, 934.
Ageusia, 1003.
Agminate folliculitis, 1080.
Agramonte on vulvovaginitis, 797.
Ahlfeld on asepsis in labor, 504; on contracted pelvis, 512; on extrauterine gestation, 497; on induction of abortion, 489; on ischiopagus, 751; on the third stage of labor, 507; and Vahle on asepsis in labor, 504.
Ahlström on atropin conjunctivitis, 916; on light-sense, 925.
Ahrens on fat-embolism of the lungs, 883.
Air, damp, 998; -embolism in abortion, 486; expired, poison in, 1185.
Ajello and Paraveandalo on uremia, 192.
Akinesia algera, 822.
Albanese on caffein, 1114.
Albarran on hypertrophy of the prostate, 406; on lithotrity, 405; on movable kidney, 415.
Albers-Schönberg on rupture of the uterus, 525.
Albert's disease, 265.
Albinism, 918
Albu on intestinal antisepsis, 173.
Albumin, Spiegler's test for, 1192; test for, 1191; in the urine, 188.
Albuminous expectoration after paracentesis, 118.
Albuminuria, 188, 1192; cyclic, 188; in diphtheria, 758; from ether, 245; in pregnancy, 470; pretuberculous, 35; in typhoid fever, 21; after vaccination, 48.
Albuminuric retinitis, 926; of pregnancy, 944.
Albumose in the urine, 189; -milk, 779.
Albumoses, leukocytosis after injection of, 92.
Albumosuria, 699, 1175.
Alcohol in acne rosacea, 1082; action of, on the cortical nerve-cell, 689; in children, 801; convulsions from, 849; and digestion, 162, 1176; in erysipelas, 212; in labor, 504; in laryngeal papillomata, 1024; in poisoning by carbolic acid, 1111; -poisoning in children, 802; in purulent otitis media, 974.
Alcoholic cirrhosis of the liver, 177; neuritis and tuberculosis, 829; myocarditis, 132.
Alcoholism and heredity, 865; treatment, 823.
Aldrich on the urine, 1175.
Alexander on cystotomy, 410.
Alexander's operation, 607.
Alger on tuberculosis, 37.
Algid malarial fever, 54.
Alkalinity of fluids, 1190; and immunity, 727.
Alkaloidal tinctures, strength of, 1101.
Alkaloids, chemic properties of, 1188; of digitalis, 1115; of ipecacuanha, 1123; stearates of, 1140; of the urine, 1195.
Alkaptonuria, 34.
Allen (H.) on cretinism, 998; on foreign bodies in the esophagus, 1019.
Allen on erysipelas, 1047; on the urine, 1193.
Alling on diplopia, 900.
Allingham (H. W.) on carcinoma of the rectum, 325; on intestinal anastomosis, 295.
Allis (O. H.) on appendicitis, 292; on the hip, 375, 880.
Allison on osteomalacia, 87.
Alloxins, 77.
Allport on cataract, 937; on myringitis bullosa, 962.
Allyn (H. B.) on encephalic syphilis, 948; on heart-disease and pregnancy, 127; on summer diarrhea, 784.
Alt on diabetic retinitis, 928; on glaucoma, 922; on hypopyon, 940; on optic neuritis, 950.
Altabus on idiocy, 946.
Alternating treatment of diabetes mellitus, 86.
Altitude, effect of, on cardiac disease, 137.
Aluminum for instrument-cases, 451.
Alveolar processes, tuberculosis of, 716.
Alveoli, pulmonary, 1156.
Alzheimer on juvenile paresis, 868.
Aman on anterior kolpotomy, 647.
Amat on skin-grafting, 419.
Amaurosis in nephritis, 192.
Ambler on tuberculosis, 42.
Amblyopia, 902; from acetanilid, 931; from carbon bisulphid, 932; from chocolate, 931; exanopsia, 926; in lactation, 932; from lead-poisoning, 932; quinin-, 930; without squint, 900; tobacco, 932; toxic, 930; from veal, 931.
Ambulatory treatment of fractures, 356.
Ameba, ciliated, in pertussis, 774; cultivation of, 738.
Amebic abscess of the liver, 315; catarrhs of the intestinal tract, 59.
Ameiss on uterus didelphys, 477.
Amenorrhea, 587; mempanthis trifoliata in, 588.
Ametropia, 893; diagnosis, 895; headache from, 893; reflex symptoms in, 893.
Ammoniuria, 700.
Amnion, 461.
Amniotic fluid, suppuration of, 462.
Amœba coli and dysentery, 58.
Ampullar abortion, 497.
Amputation, 223; Berger's method, 231; Bier's method, 229; Carden's, 230; circular method, 230; of the forearm, 229; Gritti's, 229; hip-joint, 232; intrauterine, 461; at the knee-joint, 230; of the leg, 229; major, 223; method of, 225; osteoplastic, 226; osteoplastic brachio-olecranon, 226; osteoplastic metacarpo-radiocubital, 228; Sabanejeff's, 228; Samfirescou's, 226; Wyeth's method, 233.
Amyl nitrite in cocain-poisoning, 1114; in quinin-amblyopia, 931; in valvular cardiac disease in pregnancy, 469.
Amyl valerianate, 1145.
Amyloid degeneration in tumors, 706.

Amyotrophy, tabic, origin of, 686.
Anæmia infantum pseudoleukæmica, 668; splenica, 103.
Anal fissure, 327; pruritus, 327.
Analgesia in labor, 507.
Analysis of condensed milks, 746; of cow's milk, 746; urinary, in gynecology, 580; of urine, 1190.
Anarcotin, 1102.
Anastomosis, intestinal, 295; of the ureter into the bladder, 411; urethroureteral, 574.
Anatomic nomenclature, 1146.
Anatomy, 1146; of carcinoma uteri, 629; of the digestive system, 1150; of the ear, 1154; of nose in the embryo, 996; of the genito-urinary organs, 1156; of the larynx, 1156; of the lungs, 1156; of the nasal mucosa, 996; of the nervous system, 1151; of the optic nerve, 930; of the retina, 925; of the skin, 1158.
Anchylostomiasis, 197; thymol in, 198.
Anders (J. M.) on influenza, 52.
Anderson on adenoma sebaceum, 1084; on conjunctivitis, 914; on obturator hernia, 279.
Andrews (E. W.) on hernia, 284; on sulfonal, 1142; on Whitehead's operation, 326.
Anemia, blood in, 672; bone-marrow in, 95; corniferrin in, 95; disturbance of speech from, 849; ferratin in, 95; iron in, 1125; mercuric chlorid in, 95, 100; oxygen inhalations in, 95; pernicious, 98; pernicious, pathology of, 674; pernicious, spinal cord in, 850; quinin in, 95; somatose in, 95; symptomatic, 93; systolic aortic murmur in, 94.
Anencephalus, 467.
Anesthesia, acetonuria after, 252; and anesthetics, 233; best time for, 249; collapse during, 248; diabetic coma after, 252; diabetics, 252; digitalis before, 248; by freezing, 239; heart in, 248; infiltration, 235, 908; local, 233–240; local, in dermatology, 1088; in locomotor ataxia, 851; mixed, 246; nature of, 251; in rhinology, 996; Schleich's method, 235; slow, 241; uninterrupted, 247; vomiting during, 250.
Anesthetic leprosy, 860.
Anesthetics in labor, 507; safety of, 244; urine after, 245.
Aneurysm, 147; of the aorta, 148; distal ligature for, 340; double, 341; of the heart, 146; of the hepatic artery, 181; iliofemoral, 340; Macewen's method of treatment, 148; multiple, 147; of the orbit, 910; varicose, 147; of the vertebral artery, 341.
Angeiocholitis, treatment of, 322.
Angelucci on hydrophthalmus, 893.
Angina, nondiphtheric, bacteriology of, 691; nondiphtheric membranous, 789; pectoris, 140.
Angiokeratoma of the scrotum, 1064.
Angioma cavernosum, subconjunctival, 917; cavernous, of the ear, 962; of the orbit, 911.
Anhalonin, 1103.
Anhalonium Lewinii, 1103.
Anilids, 233.
Animal extracts, 1104; heat, 1172; parasites, 196; parasites in the nose, 1006.
Animals, effects of chemic compounds on, 1188.
Aniridia, congenital, 892.
Anise, 1120.
Ankylosis, bony, 883; of the hip, 880; of joints, 377; vicious, osteotomy for, 881.
Ankylostoma in pernicious anemia, 98.
Annular scotoma, 928.
Anomalies, cardiac, 786; of the ocular muscles, 900; of the ovary, 666; of the urethra, 576; of the uterus, 593.
Anorexia, 161; hysteric, 811, 812.
Anosmia, 1003.
Anst-Lawrence on inversion of the uterus, 527.
Antagonism between tuberculosis and syphilis, 1093.
Antal on phosphorus-poisoning, 1133.
Anterior kolpotomy, 609, 644; poliomyelitis in children, 794; poliomyelitis in diabetes, 684.
Anthony on hypertrophy of the breast, 546; on lycetal, 1126.
Anthrax, 60; intestinal, 60, 173; septicemia, 60, 126.
Antianthrax serum, 734.
Antibodies, 726; of cholera and typhoid fever, 729.
Antichievich on glycerin-poisoning, 802.
Antidote for chloral, 1113.
Antinosin, 1127.
Antiphthisin, 42; in tuberculosis, 776.
Antipyonin in conjunctivitis, 943.
Antipyretics in fever, 68.
Antipyrin as an anesthetic, 233; in children, 801; in chorea, 801; in conjunctivitis, 914; in diabetes mellitus, 86; in diphtheria, 764; in laryngitis, 996; in pertussis, 801; in pneumonia, 801; in pruritus, 1059; in rhinology, 996; in typhoid fever, 801.
Antipyrin amygdalate in pertussis, 1102.
Antisepsis, intestinal, 173; intestinal, in chlorosis, 97; Schleich's method, 200.
Antiseptic surgery, 200; tampon, 431.
Antiseptics, intestinal, in summer diarrhea, 784; nasal, 996; new, 210; in tuberculosis, 38.
Antispasmin in pertussis, 1108.
Antistreptococcic serum, 50, 219, 734; in puerperal sepsis, 542.
Antitoxic serum of diphtheria, 732; in typhoid fever, 733.
Antitoxin, accidents after, 763; in diphtheria, 723, 733, 755, 758; of diphtheria in private practice, 760; eruptions after, 763; in erysipelas, 50; in syphilis, 1095; in tetanus, 840.
Antitoxins, 726; and toxins, 735.
Antitubercle-serum, 40.
Antivenene, 69, 736.
Anton on the organ of Jacobson, 1154.
Antonelli on dacryoadenitis, 909; on myopia, 897.
Antrum, caries of, 979; disease, 980; empyema of, 1008; hemorrhage from, 1009; opening the, 1009; transillumination of, 1008.
Anus, artificial, for dysentery, 311; diseases of, 325; lymphatics of, 1148; vulvovaginalis, 566.
Aorta, aneurysm of, 148; diseases of, 147; stenosis of, 148.
Aortic murmur in anemia, 94; regurgitation, 132; valvular diseases, treatment, 137.
Aortitis, chronic, 147; syphilitic, 682.
Aphakia, congenital, 892.
Aphasia, motor, 1028; optic, 949; uremic, 193.
Aphonia, hysteric, 807, 974, 1027; hysterotraumatic, 1028.
Aphoses, 929.
Apices, pneumopaludism of, 55.
Apolysin, 1108; in epilepsy, 819.
Apoplectiform attacks, blood in, 94.
Apostoli's treatment of tubal pregnancy, 494.
Appelstedt on deciduoma malignum, 463.
Appendicitis, 170, 287; and concretions, 171; gauze-packing in, 291; incision in, 291; operation in, 289; pathology, 170; relapsing, 290; and rheumatism, 170; sodium salicylate in, 170.
Appendicular abscess, 287.
Appendix-bacteriology, 287; vermiformis, obliteration of, 693.
Appenzeller on the eye in diabetes, 945.
Applications, intranasal, 996.
Arangino on suture-material, 209.
Arcein, 943.
Arecetin (arecolin) hydrobromate in eye-diseases, 943.
Arecolin hydrobromate, 1108.

Argentamin, 1109.
Argonin, 1109; as an antiseptic, 211.
Ariol in corneal ulcer, 940.
Aristol in corneal ulcer, 940.
Arm, amputation of, 231; enchondrosarcoma of, 231.
Armaignac on the eye, 942; on foreign bodies in the eye, 953.
Armstrong on rheumatoid arthritis, 76; on urinary suppression, 185.
Arnott (J.) in local anesthesia, 239.
Arnstein (F.) and Atoniak on pruritus, 1059.
Aromatic sulphuric acid in dysentery, 58.
Aronson on phenacetin-poisoning, 1132.
Arrhythmia, cardiac, 134, 139.
Arsenic, bullous eruption after, 1053; in chlorosis, 98; in eczema, 1034; elimination of, 1190; in lupus of the larynx, 1025; in pemphigus, 1040; in surgical tuberculosis, 222.
Arslan on adenoids, 968; on adenoids in children, 1011; on ethyl bromid, 996.
Artaud and Gadot on boxwood, 1110.
Arterial cirrhosis, 679; suture, 343; wall, structure of, 1148.
Arteries, diseases of, 147; and veins, communications between, 1148.
Arteriosclerosis of the central nervous system, 833; and the Röntgen rays, 199.
Artery, central, of the retina, 1155; hyaloid, persistent, 892; middle meningeal, 387; obstructed, 346; third coronary, 1148.
Arthrectomy, 222.
Arthritis in croupous pneumonia, 112; deformans, 780, 885; gonorrheal, in the newborn, 754; osteitis and, 370; scarlatinal, 769; suppurative, after erysipelas, 377.
Arthrodesis, 887.
Arthropathies of croupous pneumonia, 698.
Arthus on coagulation of the blood, 1162.
Articular fractures, 357.
Artificial abortion, 489; anus for dysentery, 311; respiration, 250.
Asafetida in abortion, 488.
Asaprol in children, 801; in hemorrhage, 801; in malarial fever, 801; in pertussis, 802; in vulvovaginitis, 802.
Asbestos as a surgical dressing, 201.
Ascending paralysis, acute, 861.
Ascites, 276; in hepatic cirrhosis, 179.
Ascitic fluid as a culture-medium for the diphtheria-bacillus, 722.
Aschoff on deciduoma malignum, 463; on pleurisy, 117.
Asepsis in labor, 503.
Aseptic surgery, 200; wounds, celloidin for, 202; wounds, treatment of, 202.
Aseptolin in tuberculosis, 39.
Ashhurst (J.) on trephining of the cranium, 389.
Ashmead on leprosy, 1068.
Ashton on fibroid of the uterus, 618.
Askanazy on cardiac disease, 137; on the trichocephalus dispar, 197.
Aspergillar keratitis, 115.
Aspergillosis of the lung, 698.
Aspergillus infection, 115.
Asphyxia, insufflation for, 1030; neonatorum, 547; tracheotomy for, 1030.
Aspiration in empyema, 333; -pneumonia, 698.
Assaky on leukemia, 314
Associated movements, abnormal, of the eye, 901.
Asthenic bulbar paralysis, 847.
Asthenopia, 894; electricity in, 902; and the genitalia, 894; strychnin in, 902.
Asthma, 116; paraldehyd in, 1130.
Astigmatism, 895; after cataract, 937; corneal, 895; latent, 896.
Asymmetry, congenital unilateral, 745.
Atheroma, 147; and syphilis, 147, 683.
Atkinson on typhoid fever, 20.
Atmospheric pressure and the hip-joint, 881.
Atony, intestinal, 169.
Atresia ani, 567; congenital, of the auditory canal, 961; congenital, of the hepatic duct, 782; recti, 567; of the uterus after curettage, 603; of the uterus at the menopause, 593; of the vagina and vulva, 565.
Atrophic endometritis, 601; infants, kidney in, 700; uterus, 510.
Atrophy of the liver, acute yellow, 179; in children, 783; of mucosæ in bronchitis, 109; optic, 934; progressive muscular, 684; progressive muscular, after diabetes mellitus, 84; of the prostate, 1170.
Atropin, 1109; conjunctivitis, 916; exanthem, 943; -group, 1109; in nocturnal enuresis, 796; pseudoerysipelas after, 900; in refraction, 900; stearate, 1141; in tuberculosis, 36.
Atwood on retinitis pigmentosa, 927.
Atypical croupous pneumonia, 697; muscular dystrophy, 823.
Auché and Coyne on acute yellow atrophy of the liver, 783.
Audebert on pernicious vomiting of pregnancy, 468; on puerperal eclampsia, 518.
Auditory canal, congenital atresia of, 961; external, diseases of, 959; occlusion of, 961.
Audvord on tuberculosis, 32.
Aufrecht on acute yellow atrophy of the liver, 180; on alcoholic myocarditis, 132.
Auger on bruises, 416.
Augstein on ectropion, 908.
Auld on hematogenous jaundice, 693.
Aura in puerperal eclampsia, 515.
Auricle, congenital malformation of, 958; erosion of, 958.
Auscher and Lapicque on iron, 1174.
Auscultation in the diagnosis of fracture, 358; of joints, 377; of the mastoid, 981.
Auscultatory percussion, 123.
Ausset on vaccinia, 49.
Autointoxication, epileptoid fits from, 817.
Autopsy, 1183.
Autotransfusion, 433.
Auvard on rectovaginal fistula, 573; on symphysiotomy, 535.
Avoledo on chronic otorrhea, 975.
Axenfeld on accommodation, 898; on corneal ulcer, 940; on Röntgen rays, 1182.
Axillary glands in mammary carcinoma, 259.
Axis-adjustment, delivery of the placenta, 508.
Ayers on abortion, 486; on dermoid cyst of the conjunctiva, 917; on symphysiotomy, 535; on lymphangioma of the orbit, 911; on malarial fever, 54; on ophthalmoplegia externa, 905.

Babcock on cough, 107; on thyroid feeding in insanity, 870.
Baber on papilloma of the nose, 1004; on turbinotomy, 972; and Proca on tuberculosis-serum, 732.
Bach on phlyctenular conjunctivitis, 916; on retinal detachment, 928; on sympathetic ophthalmia, 920.
Bacillus, capsule-, 715; capsulatus in hepatic abscess, 179; capsulatus misothermus, 715; colon, 721; fluorescens capsulatus in cholera nostras, 693; of foot-and-mouth disease, 714; of hemorrhagic purpura, 715; Klebs-Löffler, 755; mucosus ozænæ, 696; pathogenic anaërobic, of the intestine, 714; Pfeiffer's, 51; of the plague, 59; pyocyaneus in otorrhea, 974.
Backhaus on whey-and-cream mixture, 748.
Backward dislocation of the carpus, 374.
Bacon on deciduoma malignum, 463; on the Kraske operation, 635; on otitic cerebellar abscess, 992; on spontaneous rupture of the mastoid cells, 980.
Bacteremia, 742.

Bacteria, action of, on the cholera-vibrio, 724; in the body fluids, 712; in healthy organs, 712; influence of electricity on, 712; intestinal, in the newborn, 750; and the intestinal walls, 712; in the intestines, 172; on money, 712; motility of, 711; in the nares, 998; in pleurisy, 117; in pneumonia, 111; and Röntgen rays, 422, 712; specificity of, 711; of tonsillitis, 1014; in the urine, 190.
Bacteriologic method of Elsner, 18; technic, 736.
Bacteriology, 711; of the cervix uteri, 570; of hernial fluid, 278; of lacrimal diseases, 908; of nondiphtheric angina, 691; of ozena, 1000; in pelvic disease, 639; in typhoid fever, 718; of whooping cough, 697.
Bacteriuria, 190.
Badal on the eye in hysteria, 946; on wounds of the eye, 953; operation, 923.
Baget on syphilis, 1094.
Baginsky on scarlatina, 768; on serum-treatment of diphtheria, 761; on spinal sclerosis, 795; and Sommerfeld on bile in childhood, 745.
Baieradi on cataract, 937.
Bailey (P.) on painless tumor of the cord, 854; and Ewing on Landry's paralysis, 686, 861.
Baker on cataract, 935.
Baldwin on extrauterine pregnancy, 494; on the menopause, 593; on occipitoposterior position, 528; on rupture of the uterus, 525.
Baldy on embolism after abdominal section, 655; on hysterectomy in puerperal sepsis, 642, 643; on hysteropexy, 613, 614; on irritable bladder, 576; on ureterovaginal fistula, 574; on uterine fibroid, 622.
Baldy's operation for uterine prolapse, 605.
Ball on acute otitis media, 962.
Ballantyne on congenital teeth, 781; on fetal monstrosities, 466; and Skirving on double penis, 1157.
Ballet and Dutil on multiple neuritis, 830.
Balls-Headley on puerperal sepsis, 540.
Balsam of Peru in blepharitis, 942; in scabies, 1049.
Bamberg's theory, 109.
Bandage in aseptic wounds, 202; plaster-of-Paris, 203; zinc-jelly, for leg-ulcers, 416.
Bandaging, circular, 204; the thumb, 204.
Bandhapadia on hiccough, 822.
Bandiera on tuberculosis, 41.
Bands, vocal, vibration of, 1029.
Bannatyne on rheumatism, 72.
Banti on anæmia splenica, 103; on jaundice, 175; on valvular heart-disease, 678.
Bar on gonorrheal rheumatism in the puerperium, 540; on the Röntgen rays, 424; and Bienfait on pernicious vomiting of pregnancy, 468; and Renon on the blood of newborn infants, 716; on streptococcism in pregnancy, 474; on tuberculosis, 33.
Barabacheef on formol, 943.
Barber on gall-stones, 321.
Barbour (A. H. F.) on frozen sections in labor, 508; on puerperal insanity, 473.
Barclay on acute otitis media, 967; on the ear, 962.
Barcus on abortion, 485.
Bard on lumboabdominal palpation, 640.
Bardach on infectious diseases, 703.
Bardeleben on early motion in fractures, 356.
Bardelli on conjunctivitis, 913; on retinoscopy, 895.
Bardenheuer on splenopexy, 314.
Bardet on arecolin hydrobromate, 1108.
Bares on glanders, 61.
Bargebuehr on chylous exudates, 119.
Barie on tuberculosis, 34.
Barker on elective sensory paralysis, 831; on subcutaneous wiring of the patella, 363; on trophic nerves, 1180.
Barker (T. R.) on treatment of the puerperant, 509.
Barkwell and Birkett on deformity of the auricle, 958.
Barling (A. S.) on gastric ulcer, 266; on otitic sinus-phlebitis, 990; on syphilis, 1095.
Barlow's disease, 779.
Barnick on tuberculosis of the ear, 977.
Barometric pressure and hemorrhages, 34.
Barr on acute otitis media, 963; on ear-vertigo, 970; on Ménière's disease, 969; on otitic cerebral complications, 986; on purulent otitis media, 975.
Barrett on the epiglottis, 1019; on tobacco-amblyopia, 932.
Barrow on tubal pregnancy, 494.
Barrs on uremic bullous dermatitis, 1050.
Barsky on diphtheria, 764.
Barth on acute otitis media, 966; on loose bodies in joints, 884.
Bartholow on exophthalmic goiter, 143.
Bartlett on intubation, 1024.
Bartochevitch on petroleum disinfectant, 1131.
Barton on the teeth, 782.
Baruch (S.) on the Brand method, 28.
Barwell on club-foot, 886.
Base of the skull, fracture of, 934.
Basedow's disease, 140, 837.
Basenau on cholera-bacilli, 1186.
Basevi on the ocular stethoscope, 954.
Bassalino and Hallauer on subconjunctival angioma cavernosum, 917.
Bassini's operation, 285.
Bateman (W. A. F.) on cancer of the head of the pancreas, 343.
Bates on the eye, 944.
Bathing in cardiac disease, 135.
Batten on empyema in childhood, 335.
Battey's operation, 618.
Battle on acute inflammation of bone, 369; on the *x*-rays, 426.
Batton on Raynaud's disease, 832.
Baum on syphilis, 1099.
Baumann on thyroid extract, 89, 1105, 1169.
Bayer on anesthesia in diabetics, 252; on regeneration of lymphatic vessels, 1149.
Bayliss on placenta prævia, 483; and Hill on vasomotor nerves, 1166.
Bazy on guaiacol, 234.
Beach on otitic meningitis, 994.
Beale on mammary abscess, 216.
Beard on trachoma, 915.
Beaumont on latent hyperopia, 893.
Beausoleil on inflammation of the lingual tonsil, 1013.
Bechterew on gastric crises, 854; on voluntary dilatation of the pupil, 813.
Bechterew's treatment of epilepsy, 813.
Beck on ether anesthesia, 245; on subphrenic abscess, 268, 306.
Becker on anesthetics, 246, 252.
Beckmann on inversion of the uterus, 526; on rectal examination in labor and pregnancy, 505.
Béclère on variola, 47.
Beco on intestinal infection, 172.
Bedos on laryngeal ictus, 1029.
Bed-wetters, 831.
Behring on diphtheria, 758; and Ransom on cholera, 58.
Bekess on conjunctivitis, 916.
Bell on diabetes in children, 780; on endometritis, 601; on poisoning by oysters, 67.
Belladonna in coryza, 1001; in diabetes mellitus, 86; -poisoning, 1109.
Bellencoutre on eucain, 943.
Belt on albuminuric retinitis, 945; on retinitis pigmentosa, 927; on sympathetic ophthalmia, 921.
Benckiser on ichthyosis uteri, 626.
Benedict on the Brand method, 28.

Benign deciduoma, 488; tumors of the kidney, 412; of the larynx, 1024.
Bennett on injuries of the thumb, 374; on nerve-deafness, 973; on oversize of the fetus, 531.
Benson on acromegaly, 949.
Benton-Fanning on nystagmus, 893
Benttner on the diagnosis of pregnancy, 458.
Benzançon on tuberculosis in children, 776.
Benzoinol in phthisis, 1030.
Benzonaphtol, 1110; in summer diarrhea, 784.
Berens on nasal splints, 1007; on orthomonochlorphenol, 1130.
Bergen on erysipelas, 49.
Bergengrün on laryngeal ulcers, 1022; on lepra of the larynx, 1022; on tuberculous laryngitis, 1026.
Bergeois on advancement, 903.
Berger on ectropion, 908; on the eye in hysteria, 946; on fractures, 357; on hysteria, 925; on trional, 1144; method of amputation, 231.
Bergonié on the Röntgen rays, 423.
Berkley on alcohol, 689.
Berlin on sepsis, 218.
Bermann on nasal catarrh, 787.
Bernardy (E. P.) on fibromyoma in pregnancy, 480; on vulvovaginal anus, 567.
Bernhard on diphtheria, 758.
Bernhardt on locomotor ataxia, 854; on ptosis, 908.
Bernstein on the ear in influenza, 969; on hearing, 1181; on paralysis of the superior rectus, 900.
Berry on the vitreous, 929.
Bertelsmann on metritis, 596.
Berti on hypertrophy of the colon, 786.
Bertrand on gonorrhea, 699.
Beta-naphtol in chlorosis, 97; in epilepsy, 815; as an intestinal antiseptic, 173; -bismuth in summer diarrhea, 783.
Bettmann on cataract, 936.
Beutzen and Leber on glaucoma, 922.
Beyea (H. D.) on malignant adenoma of the uterus, 630.
Beyer (T.) on fever, 69.
Beyerinck on the cultivation of amebæ, 738.
Bezold on congenital atresia of the auditory canal, 961; on otitis in measles, 765; on tuberculosis of the ear, 977; and Rudolph on acute otitis, 964; mastoiditis, 980.
Bézy on syphilis of nerve-centers, 793.
Bianchi and Massei on aphonia, 1028.
Bicameral abscess in the temporal lobe, 992.
Biceps, rupture of, 355.
Bicycle-riding in asthma, 116; neuritis after, 831; for women, 584.
Bicycle saddle, 584, 585.
Biddle on sprains, 371.
Bidwell on inguinal colotomy, 310; on lupus, 220.
Biedert on cow's milk, 746.
Bielschowsky on Morvan's disease, 859.
Bier's method of amputation, 229; treatment, 376, 885.
Biernacke on locomotor ataxia, 854.
Bigelow on rhigolene, 239.
Biggs on immunization in diphtheria, 763.
Bignami on aortic aneurysm, 148; on typhoid fever, 30.
Bile in childhood, 745; -forming cancer-nodules in the lung, 704; -pigment in urine, 1191.
Biliary calculus, 181; colic, 182; fistula, 322.
Billings on diphtheria, 672, 756.
Bing on chronic otorrhea, 975.
Binnie on catgut, 209.
Binz on malaria, 1136; on salicylic acid, 1137.
Biondi on hemolysis, 93.
Bipolar electrolysis in hypertrophic rhinitis, 999.
Birkett on mammary abscess, 214.
Birth, fetal, and maternal blood at, 505; -palsies, 822; -rate in civilized countries, 452; -returns, 450, 451; signs of maturity at, 546.
Bischof on the nasal douche, 997.
Bishop on gangrene of the ear, 958; on pulmonary edema, 114.
Bishop (L. F.) on the umbilical cord, 461.
Bismuth salicylate in summer diarrhea, 784.
Bismuth subnitrate as an intestinal antiseptic, 173, 783.
Bissell on asphyxia neonatorum, 547.
Bistis on dislocation of the lacrimal gland, 910.
Bitterless cascara sagrada, 1112.
Bitzos on myopia, 897.
Black bilious fever, 55; water fever, 55.
Black on purulent otitis media, 974.
Blackader on eruptions simulating scarlatina, 765.
Blacker on the fourchet, 1157.
Blackwood on accidental hemorrhage, 483.
Bladder, contraction of, 402, 579; cystoscopic examination of, 577; dilatation of, 578; diseases of, 398, 576; drainage of, 400; edema of, 577; flushing the, 398; -gymnastics, 399; implantation of the ureter into, 412; intraperitoneal rupture of, 400; irritable, 576; lymphatics of, 1149; overdistended, in labor, 521; sarcoma of, in children, 800; siphonage of, 399; stone in, 404; tuberculosis of, 403; tumor of, 403; ulcer of, 402.
Blaise on tuberculosis, 41.
Blaizot on sodium fluorid, 211.
Blake on antrum-disease, 980; on foreign bodies in the ear, 957.
Blan on cholesteatoma of the ear, 978.
Blasius and Beckert on the pollution and cleansing of rivers, 1185.
Blastomycetes, 708; and sarcomata, 708; and tumors, 706.
Blastomycetic dermatitis, 1075.
Blaud's pill in chlorosis, 97.
Blaxall on rheumatism, 72.
Bleeding tumor of the nasal septum, 1005.
Blepharitis, balsam of Peru in, 942; in children, 906; ichthyol in, 944.
Blepharospasm, 905.
Blessig on syphilis of the orbit, 913.
Bleyer on the photofluoroscope, 1147.
Bligh on foot-and-mouth disease, 61.
Blind on sarcoma of the pancreas, 696.
Blindermann on gastric diseases, 671.
Blindness, color-, 1182; night-, congenital, 892; after head-injuries, 934; mind-, 949; word-, 949.
Bliss on pelvic hematocele, 544.
Block on surgery of the lung, 329.
Block's cholecystotomy, 322.
Blocq on exophthalmic goiter, 593; on syphilis of nerve-centers, 793.
Blondian on pharyngitis, 1017.
Blood in anemia, 672; in apoplectiform attacks, 94; in bone-tuberculosis, 878; coagulation of, 1161; in convulsions, 94; in diabetes mellitus, 64, 90: diseases of, 90, 668; examination of, 90; fetal and maternal, at birth, 505; filaria nocturna in, 678; in general paralysis, 93; hemoglobin, percentage of, 673: hysteric vomiting of, 166; of immune animals, 728; in jaundice, 176; in malarial fever, 53; of newborn infants, 727; of newborn, tubercle-bacilli in, 716; and organs, correlation of, 669; physiology of, 1161; placental and tuberculous, 33; red corpuscles of, 675; in scarlatina, 768; specific gravity of, 673; -transfusion, 224; in typhoid fever, 718; after venesection, 672.
Blood-changes in gastric disorders, 671.
Blood-corpuscles, 91; in diphtheria, 756; red, 1184; red, formation of, 1162; volume of, 1163.

Bloodgood on drainage of the bladder, 400.
Bloodless reduction of the hip, 879.
Bloodmaking organs, diseases of, 668.
Blood-motes, 671.
Blood-serum and diphtheria, 757; toxicity of, in puerperal eclampsia, 516.
Blood-stains, detection of, 1184.
Blood-vessels, 1148.
Bloom (H. C.) on double extra-uterine pregnancy, 495; on menorrhagia, 588; on myxedema, 825; on urinary analysis in women, 580.
Blue pill in cardiac disease, 138.
Blume on gastric perforation, 167.
Blumenfeld on oil of sesamum, 1138.
Blumenthal on pentosuria, 190.
Blumer and Young on anthrax septicemia, 60, 126.
Blumreich and Jacoby on the thyroid, 1169.
Boas on gastrosuccorrhea, 161; on the gyromele, 155.
Bobbin for intestinal anastomosis, 295.
Bocchi on sarcoma of the retina, 929.
Bodies, loose, in joints, 884; molluscum, 1061.
Bodo on rachitic pelves, 514.
Body, foreign, in the orbit, 913; pituitary, 1170.
Boeck on syphilis of the tonsils, 1016.
Boeck's lotion, 1086.
Boeckel on fractures, 358.
Boehle on diseases of the aorta, 147.
Böke on foreign bodies in the ear, 959; on otitic sinus-phlebitis, 990.
Börger on typhoid fever, 733.
Bogert on intussusception, 309.
Bohland on lithemia, 78; on sodium salicylate, 1137.
Bohling on diabetes mellitus, 83.
Boinet on Addison's disease, 104; on experimental Addison's disease, 704; on nicoulin, 1128; on the suprarenals, 1168.
Boisdeau on congenital heart-disease, 144.
Boisson on hemoglobinuria, 56; on jaundice, 176; on malarial fever, 56.
Bokai on lithiasis in children, 798.
Bolegnesi on erysipelas, 50.
Bollinger on tuberculosis, 32.
Bollini on hernia, 279.
Bolognini's sign, 765.
Bolton on diphtheria-antitoxin, 759; on loose bodies in joints, 884.
Bonain on sarcoma of the nose, 1004.
Bond on animal parasites in the nose, 1006; on chronic spasm of the pharynx, 1017; on myxoma of the larynx, 1025; on typhoid fever in children, 770.
Bone, acute infectious disease of, 884; acute inflammation of, 369; cavities in, 370; diseases of, 356, 368; -disease, chronic, 878; -diseases, hydrochloric acid in, 879; -extract in leukocythemia, 1107; -lesions after typhoid fever, 24, 371; pathology of, 884; tuberculosis of, 375, 884; tuberculosis of, blood in, 878; tumors of, after typhoid fever, 24.
Bone-marrow in anemia, 95; in leukemia, 102; in osteomalacia, 87, 88; in pernicious anemia, 99.
Bonnefin on intractable vomiting, 163.
Bonnet on the arterial walls, 1148.
Bonnier on deafness of genital origin, 973; on nephritis, 192.
Bono and Marchetti on dacryocystitis, 909.
Bonome and Cervesato on tetany, 839.
Bonsdorf and Sievers on pancreatitis, 183.
Bony ankylosis, 883.
Booker on summer diarrhea, 784.
Booth on mydriasis, 813.
Borax in constipation, 1110.
Borelius on gastrectasis, 165; on uterine carcinoma, 636.
Boric acetanilid, 657.
Boric-acid erythema, 1052; in gonorrheal endometritis, 557; in intestinal atony, 168; in vulvitis, 554.
Borissoff on uterine fibroids, 616.
Bornstein on nutrose, 1130.
Borri on the ureter, 412.
Boss on placenta prævia, 483.
Bossi on atrophic uterus, 510.
Boston City Hospital, typhoid fever in, 22.
Bostroem on thrombosis of the heart, 680.
Bosworth on the cocain-habit, 997; on melancholia, 1003; on sinusitis, 1009.
Bottle-cleansing, 746.
Boucheron on varicella, 772.
Bouilly on the curet, 602.
Boureau on carcinoma, 735.
Bourdon on vaginal hysterectomy, 649.
Bouveret on gall-stones, 164.
Bovée (J. W.) on tubal pregnancy, 493.
Bourneville on obesity, 88.
Bowditch on tuberculosis, 31.
Bowen on Darier's disease, 1078; on eczema, 1034; on pernicious anemia, 98.
Bowerman on anencephalus, 467.
Bowie on Landry's paralysis, 864.
Boxwood in malarial fever, 1110.
Boyd (G. M.) on albuminuria, 1192; on extrauterine pregnancy, 495; on puerperal eclampsia, 516.
Boyer on epilepsy, 814; on synthetic remedies, 1142; on vertigo, 902.
Brabazon on rheumatoid arthritis, 76.
Brace, shoulder-, 875; spinal, 875.
Brackett on subtendinous exostosis, 265.
Bradbury on gastralgia, 163.
Bradford on slipping patella, 883; on tuberculous abscesses, 878.
Bradshaw on acute thyroiditis, 149.
Bradycardia, 139; puerperal, 544.
Brain, 1179; -abscess, rupture of, 993; -disease and purulent otitis media, 974; exploration of, with a needle, 392; medullated fibers of, 1154; operations for epilepsy, 816; -probe, graduated-pressure, 448; sarcoma of, 689; -surgery, 388; -symptoms in the plague, 60; -tumor, 392.
Braislen on larvæ in the ear, 959.
Braithwaite on carcinoma, 629; on dysmenorrhea, 591; on fungi, 711.
Bramwell on tetany, 778.
Brand method in typhoid fever, 26.
Brandenberg on lithemia, 177.
Brannin on diphtheria, 762.
Branthomme on lupus vulgaris, 1072.
Brasseur on conception in the puerperium, 511.
Brault on erythema intertrigo, 1031.
Braun on pregnancy and unruptured hymen, 520.
Braus on the photofluoroscope, 1147.
Brazilian lantana, 1110.
Breakey on granuloma fungoides, 1065.
Breaking-strain of the ribs in the sane and insane, 864.
Breast, carcinoma of, 256, 258; hysteric, 811; hypertrophy of, 546; Paget's disease of, 261; pathology of, 545.
Breath, toxicity of, 742.
Breathing, mouth-, 1012.
Breed (A.) on ovarian cyst in pregnancy, 480.
Breese on extrauterine pregnancy, 494.
Bregeal on syphilis, 1098.
Breisky on atresia of the vulva and vagina, 565; on vaginal fibroma, 562.
Breisky's method, 511.
Bremer on the blood, 90; on diabetes mellitus, 85.

Bremer's method, 90; reagent, 85.
Bremner on twins, 530.
Bresler on general paralysis, 869.
Breton on tuberculosis, 38, 39.
Brewer on Bassini's operation, 285; on the gonococcus in gonorrhea, 558; on pharyngeal hemorrhage, 1016.
Brewer's yeast in diabetes, 86.
Briddon on rupture of the bladder, 400.
Brieger on acute otitis media, 963, 966; on adenoids, 968; on carcinoma of the ear, 960; on fracture of the trachea, 1030; on otitic cerebral complications, 986, 989; on primary mastoiditis, 978; on tuberculous mastoiditis, 981; and Boer on antitoxins and toxins, 735.
Briggs on anhalonium Lewinii, 1103.
Bright's disease, 191; skin-affections in, 1049.
Brindeau on placenta prævia, 483; on vulvar rigidity, 520.
Brinton on nephritis in pregnancy, 471.
Briquet on syphilis, 1097.
Brisement forcé, 883.
Brissaud on acromegaly, 846; on exophthalmic goiter, 140, 837; and Souques on neurotic vomiting, 812.
Broadbent (W.) on acromegaly, 844; on auscultatory percussion, 123; on cardiac disease, 135.
Broadbent's sign, 122.
Broadnax on burns, 416.
Broca on congenital dislocation of the hip, 373.
Brockway on the femur, 1148.
Brocq on eczema, 1033; on local anesthesia, 1088; on psoriasis, 1036; on skin-diseases, 1086; on tuberculosis, 43.
Broers (C. K.) on involution after labor, 509.
Bröse on dermoid cyst of the cornea, 892; on gonorrheal peritonitis, 696.
Bromet and Pardoe on fracture of the skull, 389.
Bromic poisoning, 1110.
Bromin and iodin in tuberculosis, 39.
Bromism, 1110.
Bromoform in pertussis, 773.
Bromosoda, 1111.
Bronchial glands, tuberculosis of, 44; stenosis, 110.
Bronchiectasis, 110.
Bronchitis, 109; acute fibrinous, 109; atrophy of mucosæ in, 109; coal-tar creasote in, 110; creasote in, 110; membranous, 109, 699; microorganisms in, 109; senile, 109; treatment, 110.
Bronchocele, 351, 352.
Bronchus, foreign body in, 332; medication of, 1030.
Bronner on Stacke's operation, 82; on turbinotomy, 972.
Bronson on acne, 1083.
Brosch on poisoning by oysters, 67.
Brosin on emphysema after abdominal section, 656.
Brothers (A.) on fetal traumatism, 465; on funic prolapse, 533; on oversize of the fetus, 531.
Brousses and Berthier on talalgia, 742.
Brown (F. T.) on hip-joint amputation, 232; on strangulated hernia, 282; on stone in the bladder, 404; on thyroid cyst, 1017.
Brown (S.) on acromegaly, 843.
Browne on vesical calculi, 404.
Bruce on the flocculus, 1154; on thyroid-feeding in insanity, 869.
Brücke on syphilitic condylomata of the ear, 960; on voluntary dilatation of the pupil, 813.
Bruhns on nephritis, 191.
Bruises, olive-oil for, 416.
Bruit de soufflet, 454.
Bruner on the eye in locomotor ataxia, 947; on paralysis of the eye-muscles, 901.
Brunner on amblyopia, 932.
Brunner's method, 207.
Bruns on acromegaly, 845; on acute plastic iritis, 919; on asthenic bulbar paralysis, 848; on direct laryngoscopy, 1020; on lip-cancer, 258; on rachitic curves, 889; on serum-therapy of malignant growths, 255; on tuberculosis of hernia, 220.
Brunton (L.) on anhalonium Lewinii, 1104; on chloroform anesthesia, 248; on hydroxylamin hydrochlorate, 1123.
Bryan on caries of the ear, 977.
Bryant (T.) on carcinoma of the breast, 261; on mammary abscess, 214; on mixed anesthesia, 247; on obstructed arteries, 346; on rupture of the liver, 315.
Bryant's apparatus, 367.
Bubonic plague, 59.
Buccal mucosa, papilloma of, 1012.
Buchanan on rupture of the tendon of the quadriceps extensor femoris, 354.
Bucheim on cod-liver oil, 1138.
Buck on mastoiditis in diabetes, 980.
Buckingham on pneumonia in children, 790.
Budin on the iliofemoral pelvis, 514; on ligation of the umbilical cord, 509; on ophthalmia neonatorum, 549.
Buechner on amputation at the knee-joint, 230.
Buedinger on clasp-knife finger, 887.
Buist on vaccinia, 46.
Bujwid on the gonococcus, 725; on pyemia, 62.
Bulbar paralysis, 834; asthenic, 847.
Bulkley on skin-diseases, 1087.
Bull on ametropia, 895; on appendicitis, 289; on convergent squint, 904; on relapsing appendicitis, 290; on retinoscopy, 895; on rupture of the quadriceps extensor femoris. 354; on sarcoma of the orbit, 911.
Buller on choroidal sarcoma, 924.
Bullet-probing, 435; wound of the pregnant uterus, 478; of the skull, 446.
Bullock on the streptococcus pyogenes, 714.
Bullous dermatitis, uremic, 1050; eruption after arsenic, 1053.
Bumm on endometritis, 598; on puerperal sepsis, 540; on ureterovaginal fistula, 575.
Bundy on otitic facial paralysis, 967.
Bunge on iron, 1125.
Burckhart on infantile myxedema, 781.
Burckhart's operation, 1017.
Burclay on maggots in the ear, 960.
Bureau on placental transmission, 457.
Burgeois on sympathetic ophthalmia, 920.
Burger on salivary digestion, 156; on tetanus, 840.
Burgess on pharyngitis, 1017.
Buried sutures, 203, 209, 651.
Burlureaux on tuberculosis, 37.
Burnett (C.) on acute otitis media, 966; on intratympanic surgery, 972; on mastoiditis, 979; on optic neuritis, 992; on otitic cerebellar abscess, 993; on the prostate, 407; on trachoma, 915.
Burnham on the eye, 942; on opticociliary neurotomy, 921.
Burns, 416; calcium citrate in, 417; in children, 417; diarrhea from, 418; ichthyol in, 416; normal salt-solution for, 416; phenol in, 416; picric acid for, 417; potassium nitrate in, 417; powder-, 418; zinc ointment in, 417.
Burrage on anterior kolpotomy, 647.
Burrell (H. L.) on ligature of the innominate artery, 341.
Burry on the Röntgen rays, 425.
Busch and Kerr on the blood, 673.
Buschan's theory, 140.
Bushbeck and Ettinger on pelvic disease, 639.
Bussachi on hypertrophy of the prostate, 407.
Busse on pathogenic yeast, 711, 725.
Bussenius on diabetes mellitus, 84.

Butler on anesthetics, 246; on excision of the ossicles, 976.
Butlin on accessory thyroids, 351.
Button, Murphy's, 295.
Buttons, mescal, 1103, 1104.
Buxton on anesthesia, 251.
Buzzard on pneumonia, 113.
Byford (H. T.) on Alexander's operation, 607; on vaginofixation, 611.
Byrne on igniextirpation of the uterus, 637.

Cabot on hernia, 286; on ichthyosis congenita, 549, 1060; on myelocytes, 669; on relapsing appendicitis, 290.
Cacodylic acid, 1088.
Caffein, 1114; in edema of the lungs, 114; in summer diarrhea, 783.
Caiger on diphtheria, 761.
Caillé on empyema in children, 790; on tuberculous meningitis, 793.
Cajal on nerve-cells, 1152.
Calabrese on immunity, 727.
Calcification of an ovary, 650.
Calcium carbonate in the uric-acid diathesis, 186.
Calcium chlorid in hemophilia, 106; in metrorrhagia, 589; in pruritus, 1059; in urticaria, 1032.
Calcium citrate in burns, 417.
Calcium glycerophosphate in diabetes mellitus, 86.
Calcium permanganate as an antiseptic, 211.
Calcium sulphid in influenza, 1111.
Calculous pyelitis, 194.
Calculus, biliary, 181; intestinal, 171; renal, 185; renal, in women, 410, 582; salivary, 1012; urinary, 1190; vesical, 404; vesical, in pregnancy, 480.
Cale on traumatic insanity, 387.
Calgor on arsenic eruption, 1053.
Callan on the eye in myxedema, 947.
Callender on opium-poisoning, 1134.
Calomel in cardiac hypertrophy, 134; in summer diarrhea, 783; in typhoid fever, 770.
Calot on congenital dislocation of the hip, 374.
Calves' thymus in typhoid fever, 29.
Camerer on cow's milk, 746; on uric acid, 1173.
Cameron on food-poisoning, 1185; on poisoning by eggs, 67.
Cameron (J. C.) on fibromyoma in pregnancy, 480; on Laborde's method, 547; on septicemia, 63; on symphysiotomy, 534.
Cameron's theory, 454.
Campanini on malignant tumors, 253.
Campbell on the breaking-strain of the ribs, 864; on prism-exercise, 903; -Clark on puerperal insanity, 472.
Campe on uterine fibroid, 616.
Camphor in herpes zoster, 1037; in valvular cardiac disease in pregnancy, 470; carbolated, in vulvitis, 554.
Camphorated oil in edema of the lung, 114.
Canal of Cloquet, persistence of, 892; external auditory, diseases of, 959.
Cancer of the nose, 1008.
Cantani on mitral regurgitation, 131.
Cantani's diet in oxaluria, 186; powder, 1145.
Cantharidal vesication, nephritis after, 194.
Cantrell (J. A.) on circinate ringworm, 1047; on eruption from potassium acetate, 1053.
Capp on nasal pain, 1003.
Capps on the blood, 93.
Capsule-bacillus, 715; suprarenal, 1168.
Carbohydrates in the urine, 1195.
Carbolated camphor in vulvitis, 554.
Carbolic-acid-poisoning, 1111.
Carbon bisulphid, amblyopia from, 932.
Carbon dioxid and the sexual organs, 1112.
Carbonic-oxid-poisoning, 1178.
Carbuncle, 217, 219.
Carcinoma, development of, in gastric ulcer, 692; etiology of, 263; histogenesis of, 263; local eosinophilia in, 671; metastasis in, 264; multiple primary, 704; operations for, 257; origin of, 707; parasitism of, 629, 707; pathogenesis of, 626; recurrence after, 257; Rommelaere's sign, 185; serum-therapy in, 735; transmissibility of, 264.
Carcinoma of the heart, 256, 258; axillary involvement in, 259; diagnosis, 260; heredity in, 261; retraction in, 261; skin-involvement in, 261.
Carcinoma of the clitoris, 559.
Carcinoma of the ear, 958, 960.
Carcinoma of the gall-bladder, and gall-stones, 182.
Carcinoma, gastric, 167, 269.
Carcinoma of the head of the pancreas, 343.
Carcinoma, intraabdominal, supraclavicular carcinoma in, 307.
Carcinoma of the iris, 920.
Carcinoma of the kidney, 185, 414.
Carcinoma of the lacrimal gland, 909.
Carcinoma of the larynx, 1025.
Carcinoma of the limbus, 917.
Carcinoma of the lip, 258.
Carcinoma of the liver with cirrhosis, 695.
Carcinoma of the lung, 120.
Carcinoma of the mastoid, 981.
Carcinoma of the middle ear, 976.
Carcinoma of the optic nerve, 935.
Carcinoma of the ovary, 664.
Carcinoma of the pancreas, 184, 696.
Carcinoma, primary, of vagina, 563.
Carcinoma of the rectum, 325, 563.
Carcinoma of the stomach, 167, 269; spinal-cord changes in, 684; surgical treatment, 269.
Carcinoma of the thyroid gland, 351.
Carcinoma of the trachea, 697.
Carcinoma of the ureter, 700.
Carcinoma of the uterus, 626; anatomy of, 629; diagnosis of, 631; treatment, 632; varieties, 630.
Cardarelli on hydatids of the liver, 181.
Cardarelli's sign, 148.
Carden's amputation, 230.
Cardiac aneurysm, 146; anomalies, 786; arrhythmia, 134, 139.
Cardiac disease and altitude, 137; bathing in, 135; blue pill in, 138; digitalis in, 137; digitoxin in, 137; diuretin in, 137; medicinal treatment, 137; mercury in, 138; strophanthus in, 137; theobromin in, 138; treatment, 135; and uterine fibroids, 621; valvular, in pregnancy, 468.
Cardiac hypertrophy, 133, 134; of growth, 787; murmurs, 129; neuroses, 139; paralysis in chloroform-anesthesia, 249; paralysis, transfusion in, 249; rupture, 145; syphilis, 146; tuberculosis, 678; ulcer, 146.
Cardiocentesis, 131.
Cardiovascular changes of renal disease, 147.
Caries of the antrum, 979; of the ear, 977; of the mastoid, 979; of the teeth, lacrimation due to, 909; of the teeth and tuberculous cervical gland, 716; of the vertebræ, 396.
Carless on the Röntgen rays, 423.
Carleton on carbolic-acid-poisoning, 1112.
Carlucci on tuberculosis, 42.
Carmalt-Jones on turbinotomy, 972.
Carmichael on chloroform, 244.
Carnogen, 95.
Carotids, ligation of, for nasal sarcoma, 1005.
Carpenter on the brain, 1180; on hemeralopia, 924; on intussusception, 310.
Carpus, backward dislocation of, 374.
Carr on congenital opacity of the cornea, 941; on malignant tumors, 262; on tetanus neonatorum, 753.

Carstens on herpes pudendalis, 555.
Cartaz on laryngeal ictus, 1029.
Cartledge on hysterectomy in puerperal sepsis, 643.
Caruncula lacrimalis, congenital duplication of, 893.
Cary on vocal fremitus, 107.
Cascara in chlorosis, 97.
Casein in human milk, 510.
Casper on pyelitis, 414; on renal tuberculosis, 195.
Cassalt on diabetes mellitus, 86; and Chambrellent on puerperal eclampsia, 516.
Casselberry on nasal spurs, 1007.
Castellino on the brain, 1180.
Castex on ear-surgery, 982.
Castor-oil treatment of cholera, 57.
Castration in exophthalmic goiter, 593; for hypertrophy of the prostate, 406, 410; influence of, on the uterus, 640; in osteomalacia, 544.
Cataract, 935–938.
Catarrh, amebic, of the intestinal tract, 59; nasal, in children, 787; of the nasopharynx and stomach, 1010; postnasal, etiology, 1019; spring, 915; vernal, 915.
Catarrhal conjunctivitis, 914; jaundice, 175.
Catelain on mammary abscess, 215.
Catgut, chromicized, 209; sterilization of, 207; palladium, 207.
Catharsis in typhoid fever, 30.
Cathcart on cysts of the pancreas, 311.
Cathcart's exhaustion-pump, 399.
Catheter, sterilization of, 206.
Catheterization of the ureter, 582; of the kidney, 582.
Caton on acute endocarditis, 125; on rheumatic endocarditis, 126.
Catrin on malarial fever, 55.
Cautery-irons, 997.
Cautley (E.) on empyema, 333; on empyema in children, 790.
Cautley's mixture, 748.
Cavalié on the diaphragm, 1153.
Cavazani on aneurysm, 148.
Cavernous angioma of the ear, 962.
Cavities in bone, 370.
Cazin on carcinoma, 185.
Ceccherelli (A.) on chloroform-narcosis, 243.
Ceci on leukemia, 314.
Cecil on rupture of the uterus, 525.
Celiotomy, vaginal, 609; for extrauterine pregnancy, 494.
Celli on amebæ, 738; on malaria, 1136.
Celloidin for aseptic wounds, 202.
Cells, eosinophile, 670; in molluscum contagiosum, 1061; plasma-, 1160.
Cellulitis, Marmorek's serum in, 219; orbital, 910.
Centers, incoordination of, 904.
Central artery of the retina, 1155; nervous system, arteriosclerosis of, 833.
Cephaëlin, 1123.
Cerebellar abscess, otitic, 992.
Cerebral abscess, otitic, 991; arteries, syphilis of, 682; cavity, gold plug in, 390; complications, otitic, 982; concussion, 388; sclerosis, trional in, 802.
Cerebrospinal meningitis, 836.
Cerium oxalate in gastric crises, 854.
Cerna on apolysin, 1108.
Cervical dystocia, 519; fistula, median, 353; glands, tuberculous, and carious teeth, 716; ligament, 359; rib, 338; tuberculous adenitis, 1017; vertebræ, fracture of, 396.
Cervillo on stramonium-poisoning, 931.
Cervix uteri, bacteriology of, 570; congenital erosion of, 571; congenital fissure of, 571; diseases of, 570; mycosis of, 600; obstruction of, after curettage, 603; tuberculosis of, 571, 659.
Cesar on lupus, 220.
Cesarean section, 536; postmortem, 528; technic of, 537.
Cestan on fistula after abdominal section, 656.
Chabaneix on structure of the nasal duct, 943.
Chabot on hypertrophy of the prostate, 407.
Chadwick on the gonococcus, 725.
Chagres fever, 53.
Chalicosis, 115.
Chalmers on relapses in scarlatina, 767.
Chambers, nasal, and cretinism, 998.
Chambrelent on dystocia, 521.
Championnière (L.) on ether, 243; on guaiacol, 233, 1121; on hemothorax, 328.
Champneys on cystic degeneration of the chorion, 462; on deciduoma malignum, 463.
Chancre, 1097; extragenital, 1091; of the eyelid, 906; recurring, 381; of the urethra, 1099.
Chancriform tonsillitis, 1014.
Chancroid, 1097; germ of, 1097; microorganism in, 715; phenol in, 1099.
Change of color of the hair, 1084; in the form and position of the stomach, 167.
Channing on tuberculosis, 45.
Chantemesse on fever, 69; on serum-therapy, 219; on typhoid fever, 26, 28, 734.
Chapin and Morton on *x*-rays, 1147.
Chaplin on bronchitis, 110.
Chappell on tuberculosis, 38; on xerostoma, 1012.
Chaput on intestinal anastomosis, 296.
Charcot on hysteria, 945; on laryngeal ictus, 1029.
Charles on cervical dystocia, 519.
Charlot on hip-joint amputation, 232.
Charpentier on pernicious vomiting of pregnancy, 468.
Charrin on chlorosis, 96; on endocarditis, 125; on empyema, 699; on submaxillary abscess, 690; and Nobécourt on infantile growth, 457; and Nobécourt on pleurisy, 118.
Chase on tuboabdominal pregnancy, 499.
Chatin on poisoning by oysters, 67.
Chauffard and Ramond on septicemia, 63, 714.
Chauval on blepharospasm, 906; on dermoid cyst of the eyelid, 907.
Cheadle on rheumatism, 70.
Chelmonski on fever, 68.
Chemic compounds, effect of, on animals, 1188; constitution and medicinal action, 1142; properties of alkaloids, 1188; rays and variola, 47.
Chemistry of bile in children, 745; clinical, 1183.
Chenay on orbital cellulitis, 910; on scurvy, 779.
Chéron on spontaneous rupture of the uterus, 478.
Chest, wounds of, 328.
Cheyne (W. W.) on carcinoma, 257; on mammary abscess, 213; on radical operation for malignant disease, 258; on tuberculosis of bone and joints, 884.
Chiari on the capsule-bacillus, 715.
Chibret on corneal ulcer, 940; on exophthalmic goiter, 837; on keratitis, 939; on oxycyanid of mercury, 210.
Childhood, bile in, 745; cystic lymphangioma in, 348; empyema in, 334; glycosuria in, 780; sarcoma in, 781; tuberculosis in, 717.
Children, acute yellow atrophy of the liver in, 783; adenoids in, 1011; alcohol in, 801; alcohol-poisoning in, 802; anterior poliomyelitis in, 794; antipyrin in, 801; asaprol in, 801; blepharitis in, 906; burns in, 417; coryza in, 1001; croupous pneumonia in, 789; diabetes in, 780; diseases of the blood in, 786; diseases of the circulatory system in, 786; diseases of the digestive organs in, 781; diseases of the gastrointestinal tract, 783; diseases of the genitourinary system in, 796; diseases of the liver in, 782; diseases of the nervous system in, 791; diseases of the respiratory system in,

787; empyema in, 790; enlarged bronchial glands in, 789; enuresis in, 796; erysipelas in, 777; genital tuberculosis in, 659; glycerin-poisoning in, 802; heart-disease in, 127; hepatic cirrhosis in, 177, 782; hernia in, 280; hysteria in, 796, 810; intestinal parasites in, 786; intestinal tuberculosis in, 775; intussusception in, 309; lithiasis in, 798; lithotrity in, 406; meningitis in, 792; multiple neuritis in, 795; nasal catarrh in, 787; nondiphtheric membranous angina in, 789; noninfectious diseases in, 777; opium-poisoning in, 803; perityphlitis in, 785; pseudomembranous enteritis in, 786; rachitic, sense of taste in, 778; Raynaud's disease in, 795, 832; retention of urine in, 796; sarcoma of the bladder in, 800; sarcoma of the kidney in, 799; sarcoma of the vagina in, 800; scurvy in, 779; spinal sclerosis in, 794; spine in, 876; strangulated hernia in, 282; summer diarrhea in, 783; surgical diseases of, 875; syphilis in, 776; syphilis of nerve-centers in, 793; syphilitic joint-disease in, 381; tannigen in, 802; tetany in, 778; toxicology in, 802; tracheotomy in, 337; trichocephaliasis in, 196; trional in, 802; tuberculosis in, 775; tuberculosis of the kidney in, 798; typhoid fever in, 22, 769; urogenital tuberculosis in, 798; use of tuberculin in, 776; vulvovaginalis of, 379, 554, 797.
Chills in typhoid fever, 20.
Chincini on opening of the lateral sinus, 981.
Chinosol, 1113; in labor, 504.
Chipman on transverse vaginal septum, 566.
Chittenden on iron, 1125; on the nucleins, 1128; and Mendel on alcohol, 1177; and Mendel on digestion, 162.
Chittick on diabetes mellitus, 86.
Chlapowski (F.) on pelvic disease, 638.
Chloral hydrate in alcoholism, 823; chemic antidote for, 1113; in labor, 507; in puerperal eclampsia, 518; in puerperal insanity, 472; in tetanus, 843; in tetanus neonatorum, 753.
Chloralamid in tetanus, 843.
Chlorin-water in typhoid fever, 30.
Chloroform anesthesia, 248; as an anesthetic, 242; cardiac paralysis in, 249; in coryza, 1001; in labor, 507; -narcosis, temperature in, 243; in puerperal eclampsia, 518; in the urine, 1191.
Chloroformization during sleep, 243.
Chlorosis, 96, 587; anemic in, 98; beta-naphtol in, 97; Blaud's pill in, 97; cascara in, 97; forced feeding in, 97; infectious origin of, 587; intestinal antisepsis in, 97; iron in, 96, 97; manganese in, 98; spleen-extract in, 1107; treatment, 97.
Chocolate-amblyopia, 931
Choked disk in locomotor ataxia, 854.
Cholecystenterostomy, 320.
Cholecystitis, infectious, 322.
Cholecystotomy, 320; extra-abdominal, 322.
Choledochotomy, 316.
Cholera, 57, 724; bacilli and uncooked milk, 1186; castor-oil-treatment of, 57; immunization against, 730; nostras, 693; opium in, 57; organism in, 57; and typhoid fever, antibodies of, 729; -vibrios and other vibrios, 724.
Cholesteatoma of the ear, 978; of the temporal bone, 977.
Cholmogoroff on rupture of the uterus, 525.
Chorea, 793; antipyrin in, 801; congenital, 794; and rheumatism, 71.
Chorion-cell sarcoma, 488; cystic degeneration of, 462.
Choroid, detachment of, 924; diseases of, 923; myoma of, 924; rupture of, 925; sarcoma of, 924; tumors of, 924.
Choroiditis, 924.
Christie on alkaloidal tinctures, 1102.
Chromic acid in erythema intertrigo, 1031; in lupus of the larynx, 1025; poisoning from the vagina, 1113.
Chromicized catgut, 209.
Chronic anterior poliomyelitis in diabetes, 684; aortitis, 147; bone-disease, 878; catarrhal otitis media, 968; disease of the tonsils, 1015; gastric diseases, 162; joint-disease, 878; myocarditis, 138; otitis media, intratympanic surgery in, 972; pancreatitis, 184; perihepatitis, 694; pharyngitis, 151; purulent otitis media, 974; saturnism, 80; spasm of the pharynx, 1017; valvular disease, 127; valvular disease and tuberculosis, 128.
Churchman on pulsating exophthalmos, 912.
Chvostek on rheumatism, 70.
Chylopericardium, 119.
Chylous exudates, 119.
Chyluria, 198; ergot in, 198; due to filaria nocturna, 198; methylene-blue in, 198; parasitic, 678; quinin in, 198; thymol in, 198.
Cicatrices, syphilitic, 1091.
Cicatricial keloid, thyroid extract in, 264.
Cigaret-habit and laryngitis, 1021.
Ciliæ, traumatic transplantation of, 916.
Ciliary body, diseases of, 918; gumma of, 919.
Ciliated ameba in pertussis, 774.
Circinate ringworm, 1047.
Circular bandaging, 204; method of amputation, 230.
Circulation, disturbances of, in infectious fever, 138; placental, 456.
Circulatory disturbances, 91; system, diseases of, 121, 678.
Circumcision and lithiasis, 798.
Cirrhosis, arterial, 679.
Cirrhosis of the liver, 177; alcoholic, 177; ascites in, 179; in children, 177, 782; eruption in, 178; etiology, 177; eye in, 951; gastric functions in, 178; gastrointestinal hemorrhage in, 178; in Hodgkin's disease, 103; hypertrophic, 178; splenic enlargement in, 178; symptoms, 178; treatment, 178; urea in, 178.
Cirrhosis, venous, 679.
Clado on enlargement of the prostate, 399.
Claiborne on hysteria, 925.
Claisse on chronic membranous bronchitis, 109.
Clapham on absence of the uterus, 595.
Clark on benzonaphtol, 1110; on the nose in phthisis, 1006.
Clark's hysterectomy, 634.
Clarke (J. J.) on cocain-anesthesia, 238; on intestinal anastomosis, 298; on sterilization of catgut, 207; on tumor of the cord, 855; on varicose aneurysm, 147.
Clasp-knife finger, 887.
Classen on R. iodocarbazol, 211; and Löb on nosophen, 1127.
Classification of puerperal sepsis, 538.
Claude on croupous pneumonia, 789; on hysteric eye-symptoms, 807.
Claus on trional in children, 802.
Cleansing of rivers, 1185.
Cleft-hand, 887; palate, 1013; palate, operative treatment, 350.
Clement on chlorosis, 587.
Clemow on typhoid fever, 29.
Climatic influence on fever, 68.
Cline on variola, 46.
Clinical chemistry, 1183.
Clitoris, carcinoma of, 559.
Cloaca congenita, 567.
Cloquet, canal of, persistent, 892.
Clover inhaler, 241.
Clubbe on intussusception, 309.
Club-foot, 885; inward rotation in, 885; *x*-rays in, 886.
Clutton on cleft palate, 350.
Coagulation of the blood, 1161.
Coakley on Cesarean section, 537; on diphtheria, 758.

Coal-tar creasote in bronchitis, 110.
Cobalt-carbonate test for free acid in the gastric juice, 1196.
Cobb on empyema of the antrum, 1008.
Coblentz on chemic constitution and medicinal action, 1142.
Cocain-anesthesia, 235; in cervical rigidity, 520; in dysmenorrhea, 592; -habit, 997; in neuralgia, 818; -poisoning, 235, 1113; stearate, 1141.
Coccidioidal infection of the skin, 1076.
Cochez on pancreatic carcinoma, 184.
Codein in diabetes mellitus, 86; in epilepsy, 1111.
Cod-liver oil, 1138; in diabetes mellitus, 86; in surgical tuberculosis, 222.
Coe on pterygium, 917.
Coe (H. C.) on Cesarean section, 536; on malignant adenoma of the uterus, 630.
Coen on stammering, 1028; and Levi on the absorptive power of the vagina, 555.
Coexistence of infectious diseases, 754.
Coffee-dyspepsia, 1115; -poisoning, 1115.
Coghill on guaiacol, 1122; on tuberculosis, 38, 43.
Cohen (J. S.) on coryza, 1001.
Cohn on glaucoma, 923; and Newman on pertussis, 697.
Cohnstein on absorption from serous spaces, 1166; on chlorosis, 1107; on lymph-formation, 1164.
Coiling of the umbilical cord, 461.
Cold abscess, 876; douche in nocturnal incontinence, 831; in fever, 68.
Cole on anesthetics, 246.
Coleman on ophthalmia neonatorum, 914.
Coley on malignant tumors, 254; on radical cure of hernia, 284.
Colic, biliary, 182; hepatic, 182.
Collapse during anesthesia, 248.
Collateral (uncrossed) hemiplegia, 833.
Colles's law, 215.
Collier on stenosis of the nares, 1006; on trigeminal neuralgia, 1002.
Collins (T.) on asthenic bulbar paralysis, 848; on the eye, 901; on glioma of the retina, 929; on sympathetic ophthalmia, 920; apparatus for transfusion, 224.
Collyer on vaginal cyst, 560.
Colombini on chancroid, 1098; on the local action of salol, 210.
Colon, congenital hypertrophy of, 786; -bacillus, 721; -bacillus in the urine in typhoid fever, 719; dilatation of, 169.
Color-blindness, 1182.
Colostomy, 310.
Colotomy, inguinal, skin-bridging in, 310.
Colpe on mycosis of the cervix uteri, 600; on pathogenic yeasts, 725.
Coma in acute yellow atrophy of the liver, 180.
Comby on antipyrin in children, 801; on glandular fever, 777; on hysteric pseudomeningitis, 806; on nondiphtheric membranous angina, 789.
Common duct, stones in, 316; iliac artery, transperitoneal ligature of, 341.
Communication between large arteries and veins, 1148.
Compensation in valvular heart-disease, 678.
Complete division of the musculospiral nerve, 383.
Complications during abdominal section, 655.
Compression in sciatica, 819; -myelitis, 876.
Compte on the phonendoscope, 107.
Comte on gastric ulcer, 266; on subphrenic abscess, 268.
Conception, 452; during the puerperium, 511.
Concretions and appendicitis, 171; gastric, 164; intestinal, 171.
Concussion, cerebral, 388.
Condamin on extrauterine pregnancy, 494; on uterine prolapse, 605.
Condensed milks, analysis of, 746.
Condyloma of the trachea, 1030; syphilitic, of the ear, 960.
Confession, hypnotic, 1184.
Congenital absence of the uterus, 595; aniridia, 892; aphakia, 892; atresia of the auditory canal, 961; atresia of the hepatic duct, 782; chorea, 794; deformities of the extremities, 1159; dislocation of the hip, 373, 879; dislocation of the humerus, 373; dislocation of the lens, 938; duplication of the caruncula lacrimalis, 893; erosion of the cervix uteri, 571; fissure of the cervix uteri, 571; glioma of the orbit, 892; heart-disease, 144; hydrophthalmus, 893; hypertrophy of the colon, 786; ichthyosis, 549; malformations, 466; malformation of the auricle, 958; malformation of the eye, 892; morphinism, 803; night-blindness, 892; opacity of the cornea, 941; predisposition to myopia, 897; ptosis, 908; syphilis, 1090; syphilis, Krisowski's sign of, 380; teeth, 781; unilateral symmetry, 745.
Conical cornea, 941.
Conium in tetanus neonatorum, 753.
Conjunctiva, cysts of, 916; dermoid cyst of, 917; diseases of, 913; excision of, in ectropion, 908; hemorrhage into, 917; pigment, adenoma of, 916; sclerema of, 917; syphilis of, 917; tumors of, 916.
Conjunctival glands, 1155.
Conjunctivitis, antipyonin in, 943; antipyrin in, 914; atropin, 916; catarrhal, 914; diphtheric, 914; formol in, 913; gonorrheal, 913; granular, 915; of the newborn, 913; petrificans, 916; phlyctenular, 916; pneumococcus in, 914; pseudomembranous, 915; after tenotomy, 916.
Conklin on pseudencephalus, 467.
Connective tissue, fibrinoid degeneration of, in inflammation, 741.
Connor on amblyopia, 902.
Consalvi on cerebrospinal meningitis, 836.
Conservation of tissue with formalin, 738.
Conservative pelvic surgery, 654; surgery on the battlefield, 429.
Constipation, 168; borax in, 1110; opium in, 169; sphincteric dilatation for, 168.
Contagion in scarlatina, 766.
Contagiousness of leprosy, 59; of inherited syphilis, 1089; of tuberculosis, 31.
Contejean on coagulation of the blood, 1162.
Contents of the healthy stomach, 1186.
Continued fever, 18; of Louisiana, 18.
Contracted bladder, 579; pelvis, 511.
Contracted tumor of the pylorus, 166.
Contraction of the bladder, 402; hour-glass, of the stomach, 167, 272.
Contracture, hysteric, 807.
Contraindications to Alexander's operation, 607.
Contusions in labor, 509.
Conus, 924.
Convergence, insufficiency of, 903.
Convergent squint, 904.
Convulsions from alcohol, 849; blood in, 94; from lead, 849.
Cook on keratitis, 939.
Coolidge on lacunar tonsillitis, 1014.
Coombs on powder-burns, 418.
Coover on eye-strain, 894.
Copemann on variola, 45.
Coppez on sarcoma of the orbit, 912; and Funk on diphtheric conjunctivitis, 914.
Cord, spinal, in pernicious anemia, 850.
Cord, umbilical, coiling of, 461: spontaneous rupture of, 461; tangling of, 461.
Corectopia, 892.
Corin on digitoxin, 1116; on pneumonia, 114.

Cormalt on acetanilid-poisoning, 1101.
Cormier on inanition-fever, 752.
Cornea, 892; congenital opacity of, 941; conical, 941; dermoid cyst of, 892; diseases of, 938; gumma of, 892; melanosarcoma of, 941; tumor of, 941; ulcer of, 939; wound of, 941.
Corneal astigmatism, 895; curvature, 895; lesions in vaccinia, 48; massage, 941.
Cornet on tuberculosis, 31.
Corniferrin in anemia, 95.
Cornil and Durante on meningitis, 689.
Cornual pregnancy, 497, 508.
Coromilas on atresia of the vulva and vagina, 565; on quinin in pregnancy, 485.
Coronary artery, embolism of, 148; third, 1148.
Corpus callosum, neuroglioma of, 689.
Corpuscles of the blood, 91.
Corr on foreign bodies in the eye, 953.
Corradi on acute otitis media, 965; on otitis interna, 971; on perforation of the membrana tympani, 961.
Correlation of the blood and organs, 669.
Cortical epilepsy, 392; nerve-cell, action of alcohol on, 689.
Corus on abdominal pregnancy, 499.
Cory on twins, 530.
Coryza, 999, 1001; in children, 1001; nosophen in, 1127.
Cotarnin hydrochlorid in metrorrhagia, 590.
Cotterill (E.) on cyst of the pancreas, 312; on syphilis, 1095.
Cough, causes of, 107; and lingual tonsils, 107.
Councilman on diphtheria, 755.
Course of pregnancy in young primiparæ, 455.
Courtade on eburnation, 979; on occlusion of the auditory canal, 961.
Courty on vaginal cyst, 560.
Cousins on hernia in children, 281; on hernia of the ovary, 664.
Coutts on infantile syphilis, 1088; on the transmission of syphilis, 777.
Cow's milk, analysis of, 746.
Cowl on fluid-corpuscles, 1163.
Cownly on ipecacuanha alkaloids, 1123.
Cox on fracture of the patella, 364.
Craig on fetal monstrosities, 467; on palsy in pertussis, 773.
Craik on puerperal eclampsia, 514.
Crainiceau on trachoma, 915.
Cramer on the knee-jerk in psychiatry, 865; on progressive muscular atrophy, 684; and Schultze on sarcoma of the retina, 929.
Cramps in nephritis, 192.
Cranial cavity, dermoid tumor of, 252.
Craniectomy for idiocy, 391.
Cranio-rachischisis, 466.
Craniotomy for idiocy, 867.
Cranium, trephining of, 389.
Creagh on typhoid fever, 22.
Creases, Houston's, 305.
Creasote in bronchitis, 110; in lupus vulgaris, 1073; in puerperal sepsis, 543; in tuberculosis, 37.
Creasote carbonate in bronchitis, 110; in tuberculosis, 45; in tuberculous adenitis, 1017.
Credé on silver, 1138.
Credé's manipulation, 507; procedure, 507; prophylaxis, 913.
Cree on placenta prævia, 483.
Creolin in laryngeal tuberculosis, 1026.
Crescents of Gianuzzi, 1151.
Cresochin, 1115.
Cresswell-Baker on labyrinthitis, 971.
Cretinism, 89; with goiter, 826; and the nasal chambers, 998; sporadic, 825; thyroid treatment, 781, 824.
Cripps (H.) on excision of the rectum, 326; on extrauterine pregnancy, 492; on gastrostomy, 270; on ovarian cyst, 660; on tubal pregnancy, 494.
Crises, gastric, in locomotor ataxia, 854.
Critchett on conical cornea, 941.
Crocker on leprosy, 1069; on psoriasis, 1036.
Crocq on diphtheria, 755.
Croly on hernia and taxis, 279.
Croom on dysmenorrhea, 591; on ovarian cyst, 660.
Cross-birth, placental, 508.
Crossed hemiplegia, 836; paralysis, 836.
Crouch on diphtheria-bacilli, 737.
Croupous esophagitis, 151; pneumonia, arthropathies of, 698; atypical, 697; in children, 789.
Crouse on inversion of the uterus, 526.
Crowell (H. C.) on fibromyoma in pregnancy, 481.
Crushes of the limbs, 418.
Cryptoscope, 420.
Crystalline lens, wound of, 952.
Culbertson on mind-blindness, 949; on optic atrophy, 934.
Cullen (J. S.) on adenomyoma of the round ligament, 664; on cyst of the vagina, 560; on hydrosalpinx, 658; on tuberculous endometritis, 600.
Cullen's formalin method, 632, 739.
Cullingworth on abdominal section, 649; on ovarian cyst, 660.
Cultivation of amebæ, 738.
Culture-media, 736; for the diphtheria-bacillus, 722, 737; urine, 737.
Cumin, 1120.
Cumol for sterilizing catgut, 207, 208.
Cumston on carcinoma of the clitoris, 559; on gonorrhea in women, 557; on metritis in pregnancy, 475; on neuralgia in women, 552; on vulvitis, 554.
Cunningham on the kidney, 1156; on the spleen, 1151.
Curability of hernia, 277.
Curatulo and Tarulli on the ovaries in osteomalacia, 666.
Curet in abortion, 487; in acne, 1083; in empyema, 336; in endometritis, 602.
Curettage, accidents of, 603; atresia of the uterus after, 603; obstruction of the cervix uteri after, 603; perforation during, 603; in trachoma, 915.
Curgenven on cocain-poisoning. 1113.
Currier on occipitoposterior position, 528; on Walcher's position, 534.
Curtis (B. F.) on gastric ulcer, 268; on malignant tumors, 254; on mixed anesthesia, 247.
Curvature, corneal, 895.
Curves, rachitic, spontaneous cure of, 889.
Cushing on vaginal hysterectomy, 620.
Cutaneous actinomycosis, 1054; manifestations of diabetes, 1050; tuberculosis, pemphigoid, europhen in, 1040.
Cutin, 209.
Cutler on congenital night-blindness, 892.
Cutthroat, 342.
Cyanid-poisoning, 1115.
Cybulski and Syzmonowicz on the suprarenal capsules, 1168.
Cyclic albuminuria, 188.
Cyclitis, plastic, 919.
Cycloplegia, 900; postdiphtheric, 918.
Cylinder, quarter-diopter, 897.
Cysts, 252; of the conjunctiva, 916; of the larynx, 1025; of the liver, 180; mesenteric, 174; of the ovary, 660; of the pancreas, 311; papillary, of the ovary, 662; thyroid, 351, 1017; traumatic dermoid, 253; tuboovarian, 659; of the vagina, 560; dermoid, 705; of the conjunctiva, 917; of the cornea, 892; of the eyelid, 907; of the orbit, 892, 912; in pregnancy, 479.
Cystic degeneration of the chorion, 462; duct, stone in, 319; incontinence in locomotor ataxia, 851; lymphangioma in childhood, 348.
Cystitis, 576; gonorrheal, 556; nosophen in, 1128; perineal

drainage in, 402; silver nitrate in, 577.
Cystoma, ovarian, 660.
Cystoscopy, 403, 577, 581.
Cystotomy in enlargement of the prostate, 399; suprapubic, for vesical hemorrhage, 399.
Cytophagy, 707.
Cytoryctes Guarnieri, 48.
Czempin on drainage, 653.
Czerny on erysipelas-toxins, 735; on gastric ulcer, 267; on malignant tumors, 253.

Dabney on blepharitis, 906.
Dacheux on irritable bladder, 576.
DaCosta (J. C.) on mammary abscess, 215; on hemorrhage after extraction of a tooth, 344.
DaCosta (J. M.) on continued fever, 65; on iron, 95, 1125.
Dacryoadenitis, 909.
Dacryocystitis, fluorol in, 909, 944.
Daggett on flushing the bladder, 398.
Dagonet on puerperal insanity, 471.
Dalby on intratympanic surgery, 972; on nerve-deafness, 973.
Dallemange on acromegaly, 843.
Dalton on stab-wound of the pericardium, 339.
Damages for malpractice, 1183.
Damm on retropharyngeal abscess, 789.
Damp air and diseases of the air-passages, 998.
Dana on bromism, 1111; on craniotomy for idiocy, 391, 867; on neuralgia, 817; on palsies after diphtheria, 762.
Dane on the blood in bone-tuberculosis, 878; on cold abscesses, 877.
Danforth on marrow-extract, 1107; on pernicious anemia, 99.
Dangers in pneumonia, 112.
Danilewski on red blood-corpuscles, 1162.
Danlos on arsenic, 1087.
Danziger on carcinoma of the middle ear, 976.
Darbonet on guaiacol, 1121.
Darde and Vigor on amblyopia, 931.
Darien on *x*-rays and the eye, 953.
Darier on amblyopia, 932; on corneal ulcer, 940.
Darier's disease, 1078.
Darlos on chancre of the eyelid, 906.
D'Arsonval and Charrin on toxins, 736.
Dastre on the liver, 1171; and Floresco on coagulation of the blood, 1162.
D'Astros on hydrocephalus, 791.
Daturin, 1109.
Dauban on scarlatinal arthritis, 769.
Dauber and Borst on acute endocarditis, 125, 681.
Davenport on pelvic disease and mental disorders, 552.
David on tuberculosis, 35.
Davidson on cardiac murmurs, 129; on the fetus in utero, 454; on formol, 944.
Davies on gangrene after scarlatina, 766.
Davis (A. A.) and Packard (C. W.) on inversion of the uterus, 527.
Davis (E. P.) on postmortem Cesarean section, 528; on postpartum hemorrhage, 544; on puerperal eclampsia, 514; on the *x*-rays in obstetrics, 458.
Davis (G. G.) on rupture of the biceps, 355; on tumor of the eyelid, 907.
Davis (J. S.) on puerperal eclampsia, 514.
Davis (N. S.) on diabetes mellitus, 82.
Davison-Schwarzchild on astigmatism, 896.
Dawbarn on siphonage of the bladder, 399; on symphysiotomy, 534.
Day on typhoid fever, 20, 26.
Deafness of genital origin, 973; hysteric, 974; from intranasal disease, 1003; nerve-, 973; of old age, 969; senile, 969; syphilitic, 973.
Deansley on colostomy, 310.
Death of the fetus, 465; after forcible straightening of the knee, 883; maternal, during labor, 528; -rate of tuberculosis, 31.
Deaver on appendicitis, 287.
De Bono on toxic amblyopia, 930.
De Bourgon on subconjunctival injections, 942.
Debove on anorexia, 161.
De Brun on malarial fever, 55.
Decidua in extrauterine pregnancy, 490.
Decidual formation, 455.
Deciduoma, benign, 488; malignum, 463, 488.
Decker on the nursing-bottle, 745.
De Cresantiques on uremia, 194.
Decussation of the optic nerve, 930, 1155.
De Dominicis on oxaluria, 186; on the thyroid, 1169.
Deformities, 874; congenital, of the extremities, 1159; in hip-disease, 881; paralytic, 886; thoracic, 108.
De Francesco on anemia, 95.
Degan on guaiacol, 234.
De Garmo on hernia, 286.
Degeneration, amyloid, in tumors, 706; cystic, of the chorion, 462; cystic, of the mammary gland, 265; sarcomatous, of a uterine fibroid, 617.
De Goubarew on puerperal eclampsia, 518.
Déjérine on neurotabes, 828; and Sottas on multiple neuritis, 830; and Thomas on homolateral pyramidal fibers, 1179; and Thomas on the medulla, 1152.
De Jolinière on peritoneal adhesions, 169.
De Kesmarky on puerperal sepsis, 542.
Delagénière on dermoid cyst in pregnancy, 479.
Delange on conservative pelvic surgery, 654.
Delavan on epithelioma of the larynx, 1025; on influenza, 1002; on papilloma of the larynx, 1024; on stammering, 1011.
Delaup on tracheotomy, 250.
Delayed puerperal sepsis, 540.
Delbet on lymphadenoma, 677.
De Lee on fetal hiccough, 464; on twin pregnancy, 529.
Delépine on izal, 1126.
Delie on syphilis of the ear, 971; on tuberculous otorrhea, 976.
Delivery of the placenta, 508.
Delorme on surgery of the lung, 329; and Mignon on the pericardium, 338.
Delstanche on otitis media, 971.
Delvic on typhoid fever, 21.
Demelin on placenta prævia, 484.
Dementia, early paretic, 868.
Demichera on quinin-amblyopia, 931.
De Mochowski on tuberculosis of the nasopharynx, 1010.
Demons on pelvic disease, 639.
Demours and Villar on fractures, 358.
Dench on acute otitis media, 967; on mastoiditis, 979; on otitic meningitis, 994; on sarcoma of the ear, 958.
Denig on cirrhosis of the liver, 951; on the eye in diphtheria, 951; on the eye in scorbutus, 951; on keratitis, 939.
Denker on epithelioma of the ear, 958.
Dennert on purulent otitis media, 974.
Dennig on septicemia, 62, 63.
Dennis on fracture of the patella, 366; on malignant disease, 255.
Dennison on tuberculosis, 42.
Denny on dermoid cyst in pregnancy, 479.
Depasse on menstruation, 586; on scarlatina, 769.
Depaul on obliteration of the os, 520.
Deposits, uric acid, 1189.
De Quervain (T.) on cervical ribs, 338.
Derby on cataract, 936.
De Renzi on influenza, 51.
Dermatitis, 1043; blastomycetic, 1075; exfoliativa neonatorum, 549, 1043; herpetiformis, 1040; medicamentosa, 1051; repens, 1045;

uremic bullous, 1050; xanthomatoides diabeticorum, 1065.
Dermatology, 1031; local anesthesia in, 1088.
Dermatomyositis, 74; acuta, 74; and rheumatism, 74; and trichinosis, 75.
Dermoid cysts, 705; of the conjunctiva, 917; of the cornea, 892; of the cranial cavity, 252; of the eyelid, 907; of the orbit, 892, 912; ovarian, 663; in pregnancy, 479; traumatic, 252.
De Roaldes on nasal polypi, 1004.
Derville on actinomycosis, 1054.
De Santi on papilloma of the nose, 1004.
Deschamps on pterygium, 917.
DeSchweinitz on encephalic syphilis, 948; on enophthalmos, 911; on entropion, 907; on injury of the eyeball, 953; on recurrent oculomotor paralysis, 905; on retinal hemorrhage, 926; on sympathetic ophthalmia, 920; on toxic amblyopia, 931.
Desiccated thyroid, thyroid extract in, 1018.
Dessy on nephritis, 191.
Destot on neuritis, 831.
Detachment of the choroid, 924; premature, of the placenta, 483; of the retina, 928.
Detection of blood-stains, 1184.
Determination of hydrochloric acid, 153.
Deutschman's migration theory, 920.
Devé on retention of fetal urine, 533.
Development of carcinoma in gastric ulcer, 692; of the pancreas, 1151.
Devine on alcohol-poisoning, 802.
Devries on merycism, 161.
De Wecker on cataract, 936; on subconjunctival injections, 942; on wounds of the eye, 952.
Dextrocardia, 144.
Deyl on the retina, 1155.
Diabète bronzé, 84.
Diabetes mellitus, 81, 1171; blood in, 84, 90; in children, 780; chronic anterior poliomyelitis in, 684; complications, 84; cutaneous manifestations of, 1050; diagnosis, 85; etiology, 81; experimental phloridzin, 82; eye in, 945; gangrene in, 84; lobar pneumonia in, 84; in married couples, 82; mastoid in, 980; pancreatic lesions in, 83; pigmentary, 84; in pregnancy, 471; progressive muscular atrophy after, 84; renal, 82; statistics of, 82, 83; symptoms, 84; urine in, 84.
Diabetic coma after anesthesia, 252; retinitis, 928.
Diabetics, anesthesia in, 252.
Diacetic acid in the urine, 187.
Diagnosis of pelvic disease, 638; of pregnancy, 458.
Diagnostic value of syphilitic cicatrices, 1091.
Diaphragm, iris as, 896; nerves of, 1153; phenomenon, 107.
Diarrhea, 169; from burns, 418; in measles, 764; saline solution in, 169; summer, in children, 783; tannalbin in, 1143.
Diathesis, uric-acid, 186.
Diathetic diseases, 69.
Diazo-reaction, Ehrlich's, 1196.
Dickinson on bicycling for women, 585; on pneumonia, 113; on renal disease, 147.
Dickinson's perineal needle, 521.
Diehl on peliosis, 1057.
Diet and diseases of the skin, 1086; in epilepsy, 815; during pregnancy, 459; Cantani's, in oxaluria, 187.
Dietetics, 1168, 1174.
Dieulafoy on appendicitis, 171; on tuberculosis of the tonsils, 1016.
Differential stethoscope, 123.
Diffuse phlegmonous gastritis, 160; scleroderma, 1063.
Digestion, 1175; alcohol and, 162, 1176; gastric, 1175; intestinal, 1176; salivary, 156; and sleep, 162.
Digestive alkalinity of the urine, 185; system, anatomy of, 1150; tract, diseases of, 690.
Digitalin in alcoholism, 823.
Digitalis and its alkaloids, 1115; before anesthesia, 248; in cardiac disease, 137; in epilepsy, 815; in pneumonia, 114; in puerperal eclampsia, 519; in tachycardia, 593.
Digitoxin, 1116; in cardiac disease, 137; in pneumonia, 114.
Digits, supernumerary, 1159.
Dilatation of the bladder, 578; of the colon, 169; of the stomach, 164; voluntary, of the pupil, 813.
Diller and Meyer on Landry's paralysis, 687, 864.
Dimitroff on syringomyelia, 859.
Dinkler on pyoktanin-mercury, 1134; on syphilis, 1097.
Dionesi on esophagitis, 151.
Diphtheria, 672, 722, 755; albuminuria in, 750; antipyrin in, 764; antitoxin in, 723, 732, 733, 755, 758; bacillus, culture-medium for, 722; staining of, 737; tenacity of, 722; blood-corpuscles in, 756; and blood-serum, 757; diagnosis, 757; eye in, 951; immunization in, 763; kidneys in, 755; nervous lesions in, 755; neurotabes after, 828; palsies after, 762; pathology, 755; pilocarpin in, 764; primary nasal, 1000; prognosis, 758; serum-treatment of, 758; of the skin, 1047; statistics, 758; tonsils in, 757; -toxin, 732.
Diphtheric conjunctivitis, 914.
Diplococcus-strumitis, 703.
Diplopia, 900.
Diplopsic points, 903.
Direct laryngoscopy, 1020.
Dirmoser on cystic degeneration of the chorion, 462.
Discharge, fluid, from the ear, 390.
Disease, antrum-, 980; chronic valvular, 127; echinococcus, 197; experimental Addison's, in the sewer-rat, 704; foot-and-mouth, 61, 714; hepatic, 174, 175; lardaceous, and syphilis, 1093; mastoid, 391, 978; pelvic, 638.
Diseases of the abdomen, 266; acute infectious, of bone, 884; of the anus, 325; of the aorta, 147; of the arteries, 147; of the bladder, 398, 576; of the blood, 90, 668; of the blood in children, 786; of the blood-making organs, 668; of bone, 356, 368; of the breast, 122; of the cervix uteri, 570; of the choroid, 923; of the ciliary body, 918; of the circulatory system, 121, 678; of the circulatory system in children, 786; of the conjunctiva, 913; of the cornea, 938; diathetic, 69; of the digestive tract, 690; of the digestive organs in children, 781; of the ductless glands, 702; of the esophagus, 151; of the external ear, 958; of the fingers, 887; of the gall-bladder, 315; of the gastrointestinal tract, 151; of the gastrointestinal tract in children, 783; genitourinary, 397; of the genitourinary system in children, 796; of the hair, 1084; of the hand, 887; of the hip, 879; infectious, 18, 754; infectious, and glycosuria, 83; infectious, and pregnancy, 473; infectious, spleen in, 703; of the intestines, 168, 292; of the iris, 918; of joints, 371; of the kidneys, 185, 410, 581; of the knee, 882; of the lacrimal apparatus, 908; of the lacrimal gland, 909; of the larynx, 995; of the lens and its capsule, 935; of the lids, 905; of the lips, 350; of the liver, 175, 315; of the liver in children, 782; of the lungs, 107; of the lymphatic system, 348; malignant, of the uterus, 623; mental, 804, 864; of the middle ear, 962; of the muscles, 354, 888; of the myocardium, 138; of the nails, 1084; of the nervous system, 382, 684, 804; of the nervous system in children, 791; of the newborn,

750; noninfectious, in children, 777; of the nose, 995; of the optic nerve, 930; of the orbit, 910; of the ovaries, 660; of the palate, 350; of the pancreas, 183, 311; of the pelvic viscera, 638; of the penis, 397; of the peritoneum, 173, 274; of the pericardium, 121; of the pharynx, 151; of the pleuræ, 107; of the prostate, 406; of the rectum, 325; of the respiratory tract, 327, 696; of the respiratory system in children, 787; of the retina, 925; of the salivary glands, 350; of the sclera, 917; of the seminal vesicles, 406; of the spinal column, 394, 875; of the spinal cord, 394; of the spleen, 311; of the stomach, 152, 266; surgical, of children, 875; surgical infectious, 742; of the tendons, 354, 888; of the testicles, 406; of the thyroid gland, 149, 351; of the trachea, 1030; of the tunica vaginalis, 406; of the ureter, 410; of the urethra, 397, 575; of the urinary organs, 575, 699; of the vas deferens, 406; of the vascular system, 338; of the vitreous body, 929; of the vulva, 553.
Disinfectant, petroleum, 1131.
Disinfecting power of soap-solution, 1186.
Disinfection of wounds, 201.
Dislocation, 371; backward, of the carpus, 374; congenital, of the hip, 373, 879; congenital, of the humerus, 373; congenital, of the lens, 938; of the femur, 375; of the lacrimal gland, 909; spontaneous, of the hip-joint, 372; of tendons, 356; of the ulnar nerve, 383.
Disorders of menstruation, 583; of the urine, 185.
Displaced kidney, 302.
Displacements of muscles and tendons, 888; uterine, in pregnancy, 475; of the uterus, 604.
Disseminated sclerosis, 685; eye in, 947.
Distal ligature for aneurysm, 340.
Distention of the fetal abdomen, 533.
Disturbances of circulation in infectious fevers, 138; of speech from anemia, 849.
Diuretin in cardiac diseases, 137; in septicemia, 63.
Diverticula, false, of the intestines, 692.
Diving, effect of, on the ear, 962.
Division of the pneumogastric and phrenic nerves, 383.
Dixey on diphtheria, 758.
Dobie on iodin-liniment, 1053.
Dobson (N. C.) on gastric ulcer, 267.
Dock (G.) on goiter, 149; on malignant endocarditis, 126; on trichomonas in the urine, 196, 743.
Döderlein on endometritis, 599; on puerperal sepsis, 540.
Doege on ovarian cyst, 660.
Döhle on syphilitic aortitis, 682.
Doering on blackwater fever, 56.
Dohrn on puerperal eclampsia, 515; on respiration in the newborn, 547.
Dolbeau on chloroformization during sleep, 243; on lithotrity, 405.
Doléris on puerperal sepsis, 540; on spontaneous rupture of the uterus, 478; and Bonnus on rupture of the uterus, 525.
Dollinger on retropharyngeal abscess, 789.
Dombrowski on optic atrophy, 934.
Domergue on serum-therapy in malignant growths, 254.
Donald on tubal pregnancy, 494; on vaginal fibroma, 562; on vaginal hysterectomy, 620.
Donellan on exophthalmic goiter, 142.
Donnief on conservative pelvic surgery, 654.
Doolittle on bicycling for women, 585.
Doran on tubal pregnancy, 494.
Dorland on Battey's operation, 618; on cystic degeneration of the chorion, 462; on tetanus neonatorum, 548; on repeated extrauterine pregnancy, 497; on uterine anomalies, 593; on valvular cardiac disease in pregnancy, 470; on vulvovaginal anus, 567.
Dorland's classification of puerperal sepsis, 538.
Dormeyer on fat, 1173.
Dorsett on the curet, 602.
Double aneurysm, 341; extrauterine pregnancy, 495; monsters, 751; penis, 1157; uterus, 594; uterus, pregnancy in, 476.
Douche, nasal, 997.
Douching in abortion, 487.
Dougall on chloral, 1113.
Douglas on scurvy, 779; on splenectomy, 314.
Dowd on cleft-hand, 887.
Downie on malformations of the auricle, 958; on syphilitic deafness, 973.
Doyen on gastric ulcer, 268.
Doyen's morcellation, 621; operation, 386, 649.
Doyne on dermoid cyst of the orbit, 892.
Drainage in abdominal section, 652; of the bladder, 400; perineal, in cystitis, 402; vaginal, 652.
Drappier on puerperal tetanus, 541.
Dresden mixture, 749.
Drews on somatose, 1140; on tannigen in children, 802.
Drinkwater on herpes zoster, 1037.
Dropsy, 129.
Drug eruptions, 1051.
Drum-cavity, hemorrhage into, 962.
Drusen in the optic nerve, 930.
Dry heat of high temperature in joint-disease, 879: treatment of rhinitis, 999.
Dsirne on ovarian tumors in pregnancy, 479.
Duane on diplopia, 900.
Dubois on hysteric anorexia, 812; on the suprarenal capsules, 1168.
Duboisin, 1109; in exophthalmic goiter, 143.
Duboys on aniridia, 892.
Dubreuilh on onychomycosis, 1085; on postserotherapic eruptions, 764; on serum-therapy, 219.
Duclos on dacryocystitis, 909, 944; on ophthalmoplegia, 905.
Duckworth (D.) on pneumonia, 113; on rheumatism, 71.
Ducrey on chancroid, 715, 1098.
Duct, Gärtner's, patency of, 563; omphalomesenteric, 169; pancreatic, obstruction of, 184; thoracic, injury of, 348.
Ductless glands, diseases of, 702.
Dührssen on extrauterine pregnancy, 494; on vaginal fixation, 522, 612; on vaginal hysterectomy, 648.
Dührssen's treatment of puerperal eclampsia, 515.
Dürck on lightning-stroke, 741.
Dufau on adhesol, 212.
Duffield on typhoid fever, 30.
Dufour on cataract, 935; on encephalic syphilis, 949; on ophthalmoplegia, 905.
Duhousset on tribadism, 453.
Duhring's disease in concentric circles, 1041; pathology of, 1040, 1042; in pregnancy, 1041; and Hartzell on papuloulcerative skin-disease, 1081.
Duke on diabetes mellitus, 83; on dysmenorrhea, 591.
Du Magny on metritis, 596.
Dumontpallier on curettage, 602; on tuberculosis, 33.
Dunbar on cholera-vibrios, 724.
Duncan on corneal ulcer, 940; on endometritis, 599; on malignant adenoma of the uterus, 630; on metritis, 596.
Dungern (V.) on the diphtheria-bacillus, 722.
Dunham on alcoholism, 823.
Dunlop on oxaluria, 1190.
Dunn on congenital aphakia, 892; on keratitis, 939; on refraction, 897.
Dunning on interstitial pregnancy, 497.
Duodenal perforation, 167; ulcer, 170, 294.
Duplication, congenital, of the caruncula lacrimalis, 893.
Dupray on carcinoma, 185.
Dupuy (V.) on congenital chorea, 794.

Durand on the infundibulo-pelvic ligament, 1157.
Duret on bronchiectasis, 110; on drainage, 652.
Durr on chronic aortitis, 147.
Dust and tuberculosis, 32.
Dutto and Lo Monaco on the thyroid, 1169.
Dwight on anus vulvovaginalis, 566.
Dysbasia hysterica, 974.
Dysentery, 58; artificial anus for, 311; benzonaphtol in, 1110.
Dysmenorrhea, 590; cocain in, 592; intermenstrual, 591; membranous, 590; morphin in, 592; and sterility, 451; treatment, 591.
Dyspepsia, coffee-, 1115.
Dysphagia due to mycosis 151.
Dystocia, cervical, 519; fetal, 528; after hysteropexy, 522, 614; maternal, 511; following vaginofixation, 524; after ventrofixation, 522, 614; in young primiparæ, 455.
Dystrophy, atypical muscular, 823.

Eagleson on abdominal pregnancy, 499.
Ear, 958; anatomy of, 1154; carcinoma of, 958, 960; caries of, 977; cavernous angioma of, 962; -disease, epilepsy from, 970; effect of diving on, 962; epithelioma of, 958, 961; exostoses of, 960; external, diseases of, 958; larvæ in, 959; and the eye, 969; fibroma of, 960; fluid discharges from, 390; foreign bodies in, 959; gangrene of, 958; in influenza, 969; local infection of, 960; lucilia macellaria in, 959; maggots in, 959; middle, diseases of, 962; hairy granulation-tumor of, 960; massage of, 972; surgery of, 981; sarcoma of, 958, 976; sclerosis of, 971; screw-worm in, 959; syphilis of, 971; syphilitic condylomata of, 960; and the teeth, 962; -vertigo, 970.
Earle on analgesia in labor, 507.
Early motion in fractures, 356; paretic dementia, 868.
Eastern Shore, endemic fever of, 18.
Eaton on pertussis, 773.
Ebstein on hematemesis, 167; on herpes zoster, 1038.
Eburnation, 979.
Eccles on the great omentum, 1150.
Echinococcus of the spleen, 314; cysts of the liver, 180; disease, 197.
Eclampsia, infantile, 515; puerperal, 514.
Ectopia lentis, 892.
Ectopic gestation, 490.
Ectropion, 908; excision of the conjunctiva in, 908; of eyelids, 892.
Eczema, 1033; due to malaria, 1033; after nephritis, 191; of the nipple, 255; perioral, 1033; treatment, 1034.
Edebohls on abdominal section, 651; on buried sutures, 651; on hysteropexy, 614; on pelvic disease, 638.
Edema of the bladder, 577; of the larynx, 1022; of the lungs, 114; vasomotor, 149.
Edematous optic neuritis, 933.
Eden on the placenta, 456.
Edes, on exophthalmic goiter, 143, 837; on neurotic vomiting, 812.
Edgar on puerperal eclampsia, 518; on symphysiotomy, 535.
Edge on abdominal section, 649; on uterine prolapse, 605.
Edinburgh method, 244.
Edmunds on the thyroid, 1169.
Edson on tuberculosis, 39.
Education, obstetric, 450.
Edwards (W. A.) on aortic regurgitation, 132; on chronic fibrous myocarditis, 134; on hepatic cirrhosis in children, 782; on hydrocele of the labium majus, 564; on urethral anomaly, 576; on vulvitis, 554.
Edwards (W. F.) on vaccination, 49.
Eeman on nasal diphtheria, 1000.
Effects of nutrition upon the teeth, 782.
Effusion, pericardial, 121.
Eggs, poisoning by, 67.
Ehlers on leprosy, 1070.
Ehrlich's myelocyte, 669.
Eichberg on hepatic cirrhosis, 178.
Eichengrün on iodoformin, 1123.
Eichhoff on europhen, 1087.
Eichholz on diet during pregnancy, 459.
Eichhorst on empyema in children, 790; on pyelitis, 194; on uric-acid calculi, 185.
Einhorn on achylia gastrica, 161; on gastritis, 160; on Töpfer's method, 153.
Einthoven on sight, 1182.
Eiselberg on hour-glass stomach, 273.
Eisendrath on ether, 246; on exophthalmic goiter, 352.
Eisenhart on hydrocele in the woman, 564.
Eisenschnitz on nephritis, 194.
Elder on Cesarean section, 536; on fibromyoma in pregnancy, 480; and Hutchison on the fetal and maternal blood at birth, 505.
Elective sensory paralysis, 831.
Electric current, action of, on bacteria, 712; treatment of, exophthalmic goiter, 143.
Electricity in asthenopia, 902; in sciatica, 819; in sterility, 451.
Electrolysis, bipolar, in hypertrophic rhinitis, 999; of nasal spurs, 1007; for nevi, 265; in stricture of the nasal duct, 943; in stricture of the urethra, 397.
Eleneff on encephalic syphilis, 948.
Elephantiasis of the vulva, 558.
Elimination of arsenic, 1190; of iron, 94; of lime-salts, 778.
Eliot on variola, 46.
Elischer on tubal pregnancy, 494.
Ellett on plastic cyclitis, 919.
Ellinger on dietetics, 1174.
Elliott on immediate suture of the gall-ducts, 319; on vesical hemorrhage, 399; test, 1193.
Ellis on cataract, 937.
Ellis (E. E.) on symphysiotomy, 535.
Elmer on eyestrain, 894.
Elsberg on cataract, 937.
Elschnig on papillitis, 934.
Elsner on malt extracts, 1127; on typhoid fever, 25, 718; bacteriologic method, 18; method of diagnosis in typhoid fever, 25.
Emanuel on carcinoma uteri, 630; on malt extracts, 1126; on tuberculosis of the cervix, 599; and Wittkowski on endometritis in pregnancy, 475.
Embley on aneurysm of the heart, 145.
Embolism, 148; after abdominal section, 655; of the coronary arteries, 148; fat, of the lungs, 883.
Embolus of the optic nerve, 934.
Embryo, nose in, 996.
Emetin, 1123; in dysentery, 58.
Emmerich on alcohol in children, 801; and Scholl on serum-therapy in malignant growths, 255.
Emmet (B.) on urethroureteral anastomosis, 574.
Emphysema of the abdominal wall after abdominal section, 656; subcutaneous, during labor, 527.
Empyema of the antrum, 1008; aspiration in, 333; in children, 334, 790; curet in, 336; due to Friedländer's capsule-bacillus, 698; of the frontal sinus, 910; after lobar pneumonia, 119; mastoid, 965; due to proteus vulgaris, 699; resection for, 333; treatment, 333.
Encephalic syphilis, 948.
Enchondrosarcoma of the arm, 231.
Endemic fever of the Mediterranean, 18, 154.
Endocarditis, acute, 123; and gonorrhea, 681; malignant, 123; in rheumatism, 70, 125, 126; after tonsillitis, 125; tuberculosis, 126.

Endocervicitis, gonorrheal, 557.
Endometritis, 597; atrophic, 601; curet in, 602; diphtheritica dermatomyositis, 541; exfoliativa, 598; frequency of, 598; gonorrheal, 557, 600; and influenza, 599; irrigation in, 601; pathology of, 599; postabortum, 598; postclimacteric, 601; in pregnancy, 475; simple, 597; and sterility, 601; toxic, 598; treatment, 601; tuberculosis, 599; venesection in, 601.
Endometrium, 602; tuberculosis of, 599.
Endothelial tumors of the orbit, 912.
Endothelioma, 704.
Enema, saline, in hemorrhage, 344.
Energy of muscular work, 1171.
Engel on bacteriuria, 190; on diphtheria, 762; on tannalbin, 1143.
Engelmann on hysteroneuroses, 819; summer diarrhea, 783.
English on cardiac arrhythmia, 139.
Engström (O.) on supernumerary ovaries, 666.
Enlarged bronchial glands in children, 789; prostate, 406.
Enlargement of the prostate, cystotomy in, 399.
Ennesbuske on cardiac disease, 136.
Enophthalmos, 911.
Enterectomy, 298.
Enteritis, pseudomembranous, in children, 786.
Enteroptosis, 158; intraabdominal pressure in, 159.
Entomology in medical jurisprudence, 1183.
Entropion, 907.
Enuresis in children, 796; nocturnal, 796; treatment of, 1116.
Eosinophile cells, 670; nature of, 671; vanillin-reaction of, 668.
Eosinophilia, local, in carcinoma, 671.
Eperon on myopia, 898.
Ephedrin hydrochlorate, 920.
Ephraim on appendicitis, 171.
Epidemics of sore throat, 64.
Epidermidalization, 625.
Epididymitis, 380.
Epiglottis, 1019.
Epilepsy, 813; adonis vernalis in, 815; apolysin in, 819; Bechterew's treatment, 813; betanaphtol in, 815; brain-operations for, 816; cortical, 392; diet in, 815; digitalis in, 815; from ear-disease, 970; eye in, 946; Flechsig treatment, 813; horse-nettle in, 814; Jacksonian, 388; peppermint in, 815; reflex, 815; salol in, 815; simulo in, 814; sodium salicylate in, 815; solanum carolinense in, 814; thyroid extract in, 815; trephining for, 816; trional in, 814.
Epileptoid fits from autointoxication, 817.
Epiphyseal separation of the lower end of the femur, 358.
Episcleritis, 917.
Epispadias, 1156.
Epistaxis, treatment, 1002.
Epithelial nodosities of Ferreol, 73.
Epithelioma of the ear, 958, 961; of the eyelid, 907; of the larynx, 1025; of the mastoid, 981; of the nose, 1008.
Equilibration, 1181.
Erb on akinesia algera, 822.
Ercole's method, 371.
Erdmann on amputation, 224; on chemic constitution and medicinal action, 1142.
Ergot in abortion, 488.
Ergotin in chyluria, 198.
Erhlich's diazo-reaction, 1196.
Erosion of the auricle, 958; congenital, of the cervix uteri, 571.
Erskine on Laborde's method, 547; on purulent otitis media, 974.
Eruptions after antitoxin, 763; bullous, after arsenic, 1053; drug, 1051; in hepatic cirrhosis, 178; iodic, 1051; mercurial, 1052; from potassium acetate, 1053; from quinin, 1052; simulating scarlatina, 765; in typhoid fever, 20.
Erysipelas, 49, 212; aconitin in, 50; alcohol in, 212; antitoxin in, 50; in children, 777; etiology, 49; ichthyol in, 212; toxins in malignant tumors, 253; Marmorek's serum in, 219; in the puerperium, 49; Renoy's treatment, 51; and skin-lesions, 1047; suppurative arthritis after, 377; synovitis after, 377; in syphilis, 1096; -toxins in malignant disease, 735; treatment, 50.
Erythema, acute exudative, 1058; from boric acid, 1052; centrifugum, 1071; exudativum multiforme, 1031, 1057; intertrigo, chromic acid in, 1031; multiform, 1031; nodosum and rheumatism, 71, 72; papulo-vesico-bullosum et necroticans, 1047; recurrent scarlatinoid, 1032; scarlatinoides following mercurial ointment, 1052; superficial, 1031.
Erythroblasts, 675.
Erythrocytes, 191, 675.
Erythrophleum, 1117.
Escat on acute otitis media, 967.
Escherich on diphtheria, 757.
Eserin sulphates in glaucoma, 923.
Eskridge on otitic sinus-phlebitis, 990.
Esmarch bandage in hemorrhage and shock, 344.
Esophageal stenosis, 151.
Esophagitis, croupous, 151.
Esophagoscope, 152.
Esophagus, carcinoma of, 152; diseases of, 151; foreign bodies in, 1019; jack-stone in, 426; tuberculosis of, 151.
Esquirol on puerperal insanity, 472.
Essen on trichorrhexis nodosa barbæ, 1085.
Estes on cerebral cavity, 390.
Estimation of hemoglobin, 90.
Estländer's operation, 343.
Ether, after-effects of, 247; albuminuria from, 245; as an anesthetic, 242; and the kidneys, 245; -narcosis, oxygen after, 247.
Etheridge on abscess of the ovary, 666; on urinary analysis in women, 580.
Etherization, pneumonia after, 250.
Ethyl bromid in rhinology, 996; -chlorid as an anesthetic, 240; in hysteric aphonia, 807, 1027.
Étienne on pyosepticemia, 63; on typhoid fever, 19.
Ettles on the diazo-reaction, 1196.
Eucain, 234, 1117; in the eye, 943.
Eucalyptus oil in scarlatina, 769.
Eudoxin, 1127.
Eulenburg on obesity, 88.
Eulenstein on otitic sinus-phlebitis, 991.
Europhen in bronchorrhea, 1030; in skin-diseases, 1087; in syphilis of the pharynx, 1016.
Eurythrol, 1107.
Eustache on cervical dystocia, 519; on pregnancy in a double uterus, 477; on vaginal cyst, 560.
Evans on ptosis, 908.
Everbusch on trachoma, 915.
Everitt on pelvic disease and mental disorders, 552.
Evetsky on actinomycosis of the lacrimal sac, 910.
Evolution, spontaneous, 532.
Ewald on equilibration, 1181; on exophthalmic goiter, 142; on lumbar puncture, 858; on pernicious anemia, 100; on thyroiodin, 1105; on ulcer of the stomach, 266.
Ewart on guaiacum, 1123; on pericardial effusion, 121.
Ewetzky on encephalic syphilis, 948; on sclerema of the conjunctiva palpebra, 917.
Ewing on diphtheria, 672, 757.
Exalgin, 1119.
Examination of blood, 90; external, in labor, 505; external of the larynx, 1020; of the heart, 122; rectal, in labor and pregnancy, 505.
Exanthem, atropin, 943; peritoneal, measles, 765; sulfonal, 1054.
Excessive hemorrhage, treatment, 345; size of the fetus, 531.

Excision of the conjunctiva in ectropion, 908; of the knee-joint, 375; of lupus, 220; of nevi, 265; in orthopedic surgery, 882; of the ossicles, 976; of the rectum, 326; of the sac for hydrocele, 408; of tuberculous glands, 222.
Exophthalmic goiter, 140, 352, 702, 837, 1018; abortive, 142; castration in, 593; diagnosis, 141; duboisin in, 143; electric treatment, 143; etiology, 140; without exophthalmos, 142; eye in, 951; galvanism in, 143; iron in, 143; manganese in, 143; medulla oblongata in, 140; and the menopause, 592; mental changes in, 864; nuclein in, 143; operation in, 143; picrotoxin in, 143; potassium bromid in, 143; and pregnancy, 470; prognosis, 142; Schott method in, 143; sodium glycerophosphate in, 143, 837; splenic extract in, 143; symptoms, 141; tachycardia in, 837, 838; thymus gland in, 143; thyroidin in, 143; treatment, 142.
Exophthalmos, pulsating, 912.
Exorbitism, 911.
Exostosis of the ear, 960; subtendinous, 265.
Expectoration, albuminous, after paracentesis, 118.
Experimental Addison's disease in the sewer-rat, 704; phloridzin-diabetes, 82; therapeutics, 1100.
Expired air, poison in, 1185.
Exploration of the brain with a needle, 392.
Expressio placentæ, 507.
Expression in trachoma, 915.
Expulsion of the amniotic sac alone, 485; of the placenta, 507.
External auditory canal, diseases of, 959; ear, diseases of, 958; ear, larvæ in, 959; examination in labor, 505; examination of the larynx, 1020; tuberculosis, 45; urethrotomy, 397.
Extirpation of lupus vulgaris, 1072.
Extraabdominal cholecystotomy, 322.
Extract, animal, 1104; of malt, 1126; of spleen in exophthalmic goiter, 143; suprarenal, in Addison's disease, 104; of thymus gland in exophthalmic goiter, 143.
Extraction of the malleus, 976; of teeth, hemorrhage after, 344.
Extractor, Wetherla's, 1024.
Extradural abscess, 992.
Extragenital chancres, 1091.
Extraperitoneal rupture in tubal pregnancy, 494.
Extrauterine pregnancy, 490; Apostoli's treatment, 494; decidua in, 490; diagnosis, 492; double, 495; with entopic gestation, 496; extraperitoneal rupture in, 494; and hematocele, 492; hemorrhage in, 491; interstitial, 497; morphin-injections in, 501; repeated, 497; rupture in, 491; treatment, 501; twins in, 495; vaginal celiotomy for, 494, 502.
Extremities, congenital deformities of, 1159.
Exudates, chylous, 119; pleural, 117.
Exudative erythema, acute, 1058.
Eye, 890; abnormal associated movements of, 901; congenital malformations of, 892; in diabetes, 945; in diphtheria, 951; and the ear, 969; effect of lightning on, 934; in epilepsy, 946; eucain in, 943; in exophthalmic goiter, 951; foreign bodies in, 951; formol in, 943; functional anomalies of, 901; in gout, 950; in hepatic cirrhosis, 951; in hereditary ataxia, 947; "hot," 950; in hysteria, 945; in intracranial tumors, 948; in locomotor ataxia, 947; in measles, 951; in myxedema, 947; in nasal disease, 950; normal growth of, 892; oil of guaiac in, 943; rupture of, 953; in scorbutus, 951; in syphilis, 947; in syringomyelia, 947; in systemic diseases, 944; and teeth, 949; in tuberculosis, 951; in typhus fever, 951; and vertigo, 902; wound of, 952; *x*-rays in, 953.
Eyeball, injuries of, 951; muscles of, 1152.
Eye-glasses, 899.
Eyelids, 892; chancre of, 906; dermoid cyst of, 907; diseases of, 905; ectropion of, 892; epithelioma of, 907; furuncles of, 907; gumma of, 907; horny growths of, 907; molluscum contagiosum in, 907; tumors of, 907; vaccine-pustule on, 907.
Eye-muscles, insufficiency of, 900; paralysis of, 900.
Eye-strain, 893.
Eye-symptoms, hysteric, 807.
Eykman on blood-corpuscles, 1163.

Faayer on the Javanese pelvis, 453.
Fabricius on hydrophobia, 61.
Face, acne of, massage in, 1082; presentation of, 532.
Facial paralysis, otitic, 967.
Fage on iritis, 919; on lacrimal diseases, 909; on ozena, 1000; on rupture of the eye, 953.
Faisans on tuberculosis, 37.
Faisset on fracture of the cervical vertebræ, 396.
Faitout on pleurisy, 118.
Fallopian tubes, tuberculosis of, 45, 659.
False diverticula of the intestine, 692.
Family form of idiocy, 867.
Faradization for pernicious vomiting of pregnancy, 468; of the pneumogastric for vomiting, 163.
Farlow on lipoma of the larynx, 1022.
Farner on exophthalmic goiter, 702.
Farrar on cervical rigidity, 520.
Farron and Vignard on sarcoma of the uterus, 624.
"Fasting stomach," 162.
Fat, 1173; -embolism of the lungs, 883; -milk, 747; -necrosis, 183, 693; subcutaneous injections of, 1119.
Fawcett on gout, 81; on peritoneal fossæ, 1150.
Fayrer on purpura hæmorrhagica, 1058.
Febrile uremia, 193.
Fecal accumulation, 302.
Fecundity, 452.
Feeding, forced, in chlorosis, 97; infant, 745.
Fehling on fibromyoma in pregnancy, 480; on gonorrhea in pregnancy, 474; on puerperal sepsis, 540.
Fehling's operation for uterine prolapse, 605.
Feilchenfeld on cycloplegia, 918.
Fell on forced artificial respiration, 250.
Felsenthal on membranous rhinitis, 1000.
Female pelvis in primitive races, 453; urethra, stricture of, 575.
Femoral hernia, 286.
Femur, dislocation of, 375; epiphyseal separation of the lower end of, 358; fractures of, 358; impacted fracture of the neck of, 362; linea quadrati of, 1148; sarcoma of, 265.
Fenger on gall-stones, 181; on sacculated kidney, 414; on stones in the common duct, 316.
Fenn on chronic diseases of the tonsils, 1015.
Fennel, 1120.
Fenner on rupture of the uterus, 525.
Fenoglio and Drogoul on the heart, 1168.
Fenter (H.) on anesthetics, 246.
Fenwick on endometritis, 601; on stricture of the urethra, 397; on summer diarrhea, 784; on tumor of the bladder, 403; on ulcer of the bladder, 402; and Barnard on burns in children, 417.
Fereal on paralysis of the eye-muscles, 901.
Ferguson (A.) on biliary fistula, 322; on gall-stone operation, 322; on varices of the leg, 339.
Fermentation, gaseous, 165.

Fermi and Bretschneider on rhinitis, 999.
Fernandez on sarcoma of the orbit, 911.
Fernet on tuberculosis, 37.
Ferrand on tuberculosis, 37.
Ferranini on bacteria, 712.
Ferrari on abortion, 490; in polyneurotic psychoses, 864; and Garbini on middle-ear disease, 1014; on epithelioma of the mastoid, 981; on the middle ear, 969.
Ferratin, 1120; in anemia, 95.
Ferraud on guaiacol, 234.
Ferreol, epithelial nodosities of, 73.
Ferripyrin in metrorrhagia, 590.
Ferrous manganese citrate, 95.
Ferry on influenza, 51.
Fetal abdomen, distention of, 533; appendages, pathology of, 459; blood at birth, 505; death, 465; dystocia, 528; hiccough, 464; hydrocephalus, 792; kidneys and spleens in puerperal eclampsia, 516; monstrosities, 466; peritonitis, 479; shoulders, impaction of, 532; traumatism, 465; uterus, 510.
Fetterolf on perforation of the membrana tympani, 961.
Fetus, excessive size of, 531; pathology of, 459; retention of urine in, 533; in utero, position of, 453.
Feulard on syphilis, 1094.
Fever, absorption, 540; African, 57; antipyretics in, 68; black bilious, 55; black water, 55; Chagres, 53; climatic influence in, 68; cold in, 68; endemic, of the Mediterranean, 18, 64; glandular, 777; hay, 999, 1001; hemoglobinuric, 56; inanition, in the newborn, 547, 751; intermittent, in the puerperium, 540; malarial, 52; Malta, 18; Mediterranean, 18; mountain, 18; nature of, 67; in nephritis, 193; putrid meat in, 68; remittent, 54; rheumatic, 71; scarlet, 755; serum-therapy in, 69; simple continued, 18, 65; thermal, 18; treatment, 68; trional in, 69; tropical, 18; typhoid, 18, 718; typhus, 57; water in, 68; yellow, 58, 714.
Fevers of the South, 30.
Fibrinoid degeneration of connective tissue, 741.
Fibrinous bronchitis, 109.
Fibroid tumor of the uterus, 616; in labor, 521.
Fibroma of the ear, 960; of the vagina, 562.
Fibromyoma and pregnancy, 480.
Fibromyxoma of the nose, 1004.
Fibrosarcoma of the ovary, 664.
Fibrosis and inflammation, 740.
Fibrous myocarditis, 134.
Ficano on chronic otorrhea, 975.
Fick on metabolism, 1177.
Fiedler on ulcer of the stomach, 266.
Field-hospital, 435.
Field on myopia, 898.
Filamentous keratitis, 939.
Filaria loa, 918; nocturna, 198; nocturna in the blood, 678; sanguinis hominis, 198.
Filehne and Kionka on respiration, 1178.
Filix mas for tapeworm, 197.
Finger, clasp-knife, 887; diseases of, 887; injuries to the tendons of, 355; papillary ridges of, 1158; supernumerary, 468.
Fingland on anesthesia, 249.
Finkelstein on hemorrhagic purpura, 715; on melæna neonatorum, 754.
Finkler on pneumonia, 111.
Finley on yellow fever, 58, 714.
Finny on embolism, 149.
Finsen on variola, 47.
First rib sign, 121.
Firth on tetanus neonatorum, 753.
Fischel on congenital erosion of the cervix uteri, 571.
Fischer on lymphatics, 149; on summer diarrhea, 783.
Fischl and von Wunschheim on the blood of newborn infants, 727.
Fischler on stricture of the female urethra, 575.
Fish on vaginal hysterectomy, 632.
Fisher on cardiac hypertrophy, 134; on cretinism, 826; on tuberculosis, 45.
Fisk on sarcoma in childhood, 781.
Fissure, anal, 327; congenital, of the cervix uteri, 571.
Fistula after abdominal section, 656; biliary, 322; genital, 572; median cervical, 353; rectovaginal, 572; ureteroabdominal, 575; ureterovaginal, 411, 573; after vaginal hysterectomy, 573; vesicovaginal, 572.
Flagella, staining of, 737.
Flagellate protozoa in the intestines, 743.
Flaischlen on carcinoma uteri, 630.
Flatau on vagitus uterinus, 465.
Flechsig treatment of epilepsy, 813.
Fleiner on the stomach, 158.
Fleischl's hemoglobinometer, 90.
Flesch on perineal laceration, 521.
Flint (A.) on chyluria, 198; on contracted pelvis, 512; on stenosis of the aorta, 148.
Flocculus, 1154.
Flower on dislocation of the femur, 375.
Fluctuation, 218.
Flührer on bullet-wounds of the skull, 447.
Fluid, amniotic, suppuration of, 462; discharges from the ear, 390; hernial, bacteriology of, 278.
Fluids, acidity or alkalinity of, 1190.
Fluorol in dacryocystitis, 909, 944.
Fluoroscope, 420.
Flushing the bladder and urethra, 398.
Foerster on abortion, 485; on tubal pregnancy, 494.
Fœtus amorphus (anideus), 467.
Folds of Houston, 305.
Folet on extrauterine pregnancy, 495.
Follicular skin-disease, 1078.
Folliculitis, agminate, 1080.
Fontan on suppurative adenitis, 217.
Food-infections and intoxications, 66; -poisoning cases, 1185.
Foot, club-, 885; -disease, Madura, in America, 1055; Morton's painful affection of, 425; -and-mouth disease, 61; bacillus of, 714; mycetoma of, in America, 1055.
Forbes and Reid on ovarian dermoid, 663; on retroversio uteri in pregnancy, 475.
Forced artificial respiration, 250; feeding in chlorosis, 97; immunization, 729.
Forceps, obstetric, 533.
Forcible straightening of the knee, death after, 883.
Forcipressure, 432.
Fordyce on angiokeratoma of the scrotum, 1064; on iodic eruption, 1051; on lupus erythematosus disseminatus, 1072.
Forearm, amputation of, 229; obliquity of, 1147.
Foreign body in the bronchus, 332.
Foreign bodies in the ear, 959; in the esophagus, 1019; in the eye, 951; in the nose, 1006; in the orbit, 913.
Form of the kidney, 1156; of lenses, 899; of the spleen, 1151; of the stomach, 157.
Formalin, 1120–1158; conservation of tissue with, 738; -gelatin, 200; for sterilizing catgut, 207; for sterilizing catheters, 206.
Formanilid as an anesthetic, 233.
Formation of the decidua, 455; of red blood-corpuscles, 1162.
Formol in conjunctivitis, 913, 943.
Fort on urethral stricture, 397.
Fossæ, peritoneal, 1150.
Foster on retinal hemorrhage, 926.
Fothergill on carcinoma of the pancreas, 184; on forceps-ope-

rations, 534; on the fundus uteri in labor, 505.
Fouchet on the teeth, 949.
Fougeray and Vacher on acute otitis media, 967.
Fourchet, 1157.
Fournel on ureterovaginal fistula, 573.
Fournier on syphilis of the tonsils, 1016.
Foville on paralysis of the eye-muscles, 901.
Fowl-cholera, 65.
Fowler on bullet-wounds of the skull, 446; on the Röntgen rays, 421.
Fowler's operation (hysterorrhaphy), 615; solution in herpes pudendalis, 555.
Fox on circular bandaging, 204; on myxedema, 825; on rheumatoid arthritis, 76; on vaccination, 49.
Foxwell (A.) on alcoholic cirrhosis, 177.
Fractures, 356; ambulatory treatment of, 356; articular, 357; of the base of the skull, 934; of the cervical vertebræ, 396; diagnosis of, 358; -dislocation of the spine, 397; early motion in, 356; of the femur, 358; of the hyoid, 1019; intrauterine, 466; laryngeal, 1022; of the malleus, 962; of the neck of the femur, impacted, 362; operative treatment, 357; of the patella, 363; of the skull, 390; sutures of, 358; of the trachea, 1030.
Fränkel (A.) on deciduoma malignum, 463; on diabetes mellitus, 82; on diphtheria, 755; on obesity, 88; on phenacetin-poisoning, 1132; on Quincke's puncture, 792; on renal tuberculosis, 195; on the thyroid, 1169; on tuberculosis of the esophagus, 151; -Hochwart on Ménière's disease, 969.
Fragilitas ossium, 780.
Francis on Addison's disease, 105; on neuroglioma of the corpus callosum, 689.
François-Franck on pulmonary vasomotors, 1166.
Franck on digitalis, 1115.
Frank (L.) on fibromyoma in pregnancy, 480; on hyperidrosis, 1084; on maturity at birth, 546; on puerperal sepsis, 543; on septic peritonitis, 277.
Frank (R. W.) on sterilization of catheters, 206.
Frank's method, 278.
Franke on muscular paralysis, 355.
Franks on movable kidney, 414.
Franzolin on leukemia, 314.
Fraser on antivenene, 736; on carbolic-acid-poisoning, 1111; on fever, 69.
Frazer on appendicitis, 171.
Frederick on embolism after abdominal section, 655; on neurasthenia in women, 552.
Freeman (G. L.) on anesthesia, 241; on anus vulvovaginalis, 566; on milk, 1187; on puerperal eclampsia, 514; on spontaneous dislocation of the hip-joint, 372; on subcutaneous emphysema during labor, 527.
Freezing for anesthesia, 239; pathology of, 1044.
Freiberg on intrauterine fracture, 366.
Fremitus, vocal, 107.
Freudenberg on scurvy, 779.
Freudenthal on angioma of the nasal septum, 1005; on postnasal catarrh, 1010; on rhinoscleroma, 1078.
Freund on albuminuria, 188; on deciduoma malignum, 464; and Levy on intrauterine typhoid fever, 18, 771; on placental transmission, 457.
Freund's operation for uterine prolapse, 605.
Freyhan on lumbar puncture, 856.
Frickenhaus on the skin, 1043.
Friedenberg on atropin exanthem, 943; on exophthalmic goiter, 141; on the eye in Graves' disease, 951.
Friedenthal on bacteria, 712.
Friedenwald on the eye in hysteria, 945; on iritis, 919; on retinal hemorrhage, 926.
Friedländer's capsule-bacillus, 698.
Friedrich on malignant tumors, 253; on nephritis, 194.
Fritsch on curettage, 603; on postoperative intestinal obstruction, 303; on rupture of the uterus, 526.
Fritts on fracture of the malleus, 962.
Frohse on the nerves of the head, 1153.
Frolich on dacryocystitis, 909.
Frollington and Pratt on acetanilid-poisoning, 1101.
Fromaget and Cabannas on tetanus from eye-injury, 953.
Frontal sinus, empyema of, 910.
Fronz on tetanus neonatorum, 753.
Froriep and Beck on the hypoglossal nerve, 1153.
Frothington on ophthalmia neonatorum, 914.
Frozen sections in labor, 508.
Fruitnight on sarcoma of the kidney, 799.
Fryer on aneurysm of the orbit, 910; on foreign bodies in the ear, 959.
Fuchs on episcleritis, 917; on keratitis, 938; on keratoplasty, 941; on myopia, 898.
Fuchter on rheumatism, 73.
Fürbringer on meningitis, 792; on phenacetin-poisoning, 1132; on Quincke's puncture, 989.
Fürstner on hysteria in children, 810.
Fütherer on chlorosis, 97; on tuberculosis, 39.
Fuller and Gibbs on cardiac disease, 128.
Fullerton (A. M.) on inversion of the uterus, 527.
Fulton (A.) on empyema, 336; on fetal hydrocephalus, 792.
Function of the laryngeal ventricles, 1021.
Functional anomalies of the eye, 901; diseases of the ciliary body, 918; of the iris, 918; of the stomach, 158, 161.
Functional heart-disease in women, 552.
Fundus uteri, height of, in labor, 505.
Funic prolapse, 533.
Funke on osteomyelitis, 370; on spontaneous rupture of the umbilical cord, 461.
Furth on diphtheria, 762.
Furuncle, 217; of the eyelid, 907.
Fussell and Kelley on hepatic carcinoma, 695.

Gaarnault on topography of the skull, 979.
Gad and Flataw on reflex action, 1179.
Gaertig on uterine prolapse, 605.
Gärtner's duct, patency of, 563; fat-milk, 747.
Gaeser on influenza, 52.
Gaffié on tuberculosis in children, 776.
Gage on cold abscesses, 876.
Gaillard on hysteric pseudomeningitis, 806.
Galactagogues, 1120.
Galactorrhea, 546.
Galeazzi on shock, 218.
Galetti on acute otitis media, 963, 965.
Galezowski on glaucoma, 922; on lacrimation, 909; on ocular syphilis, 947; on retinal detachment, 928.
Gall-bladder, carcinoma of, 182; diseases of, 315.
Gall-ducts, immediate suture of, 319.
Gallega officinalis, 1120.
Gallemaertz on corneal ulcer, 940.
Gallenga on gumma of the ciliary body, 919; on the orbit, 892.
Galliard on pyloric obstruction, 271.
Gallinet on sanoform, 1137.
Galloway on skin-lesions of syringomyelia, 1056.
Gall-stones, 164, 181, 319; and carcinoma of the gall-bladder, 182; pyloric obstruction from, 271.
Galovine on dislocation of the lacrimal gland, 910.
Galtier on suppuration of the amniotic fluid, 462.

Galvanism in exophthalmic goiter, 143; in lupus vulgaris, 1073; in tachycardia, 593; in vaginitis, 556; in xerostoma, 1012.
Gamgee on synovitis after erysipelas, 377; on tracheotomy, 337.
Gangrene in diabetes mellitus, 84; of the ear, 958; of the lung, 330; after scarlatina, 766; after typhoid fever, 24.
Gans on diabetes mellitus, 87.
Ganz on dietetics, 1174.
Garber on scurvy, 779.
Garceau (E.) on hysteropexy, 613; on transvaginal surgery, 644; on trichinosis, 197.
Garland on cocain-poisoning, 1114.
Garner and Leeson on tuberculosis, 39.
Garrigues on Cesarean section, 537; on induction of abortion, 489; on kolpoperineorrhaphy, 568.
Garrod (A.) on gout, 81; on guaiacum, 1122; on rheumatism, 71; on urinary pigments, 1191; and Fletcher on rachitis, 777.
Gaseous fermentation, 165.
Gases in human milk, 511.
Gasparrini on the eye in typhus fever, 951.
Gasquet on laryngeal ictus, 1029.
Gasserian ganglion, removal of, for neuralgia, 384.
Gastralgia, 163.
Gastrectasis, 164.
Gastric carcinoma, 167; concretion, 164; crises in locomotor ataxia, 854; digestion, 1175; diseases, blood-changes in, 671; illumination in, 155; pepsin in, 691; treatment, 162; function in hepatic cirrhosis, 178; juice, 1175; acidity of, 154, 185; free acid in, 1196; hydrochloric acid in, 153; hypersecretion of, 161; indican in, 154; lactic acid in, 154; specific gravity of, 155; in typhoid fever, 19; massage, 163; perforation, 167; secretion, sodium bicarbonate and, 1139; tetany, 839; ulcer, 165, 266; development of carcinoma in, 692; microorganisms in, 165; and parotitis, 166; perforation in, 266; sugar in, 166.
Gastritis, 160; diffuse phlegmonous, 160; glandularis chronica, 160.
Gastrodiaphane, 155.
Gastroenterostomy, 300.
Gastrointestinal hemorrhage, 178; tract, diseases of, 151; tuberculosis of, 43.
Gastroptosis, 158.
Gastroscope, 156.
Gastrostomy, after-treatment, 269; leakage after, 270.
Gastrosuccorrhea, 161.
Gaudier on the heart, 546; and Péraire on mammary abscess, 215; on tuberculosis of the mammary gland, 717.
Gaulard on pernicious vomiting of pregnancy, 468; on puerperal sepsis, 542.
Gaupillat on iritis, 919.
Gauthier on hepatic cirrhosis, 178.
Gautier on ichthyosis uteri, 624.
Gauze, acetanilid, 657; iodoform, 206; -packing in appendicitis, 291.
Gay on ether, 244.
Gayton on diphtheria, 761.
Gebhard on ichthyosis uteri, 624.
Gebhardt on interstitial extrauterine pregnancy, 497.
Geigel on cardiac murmurs, 130.
Geiger on trachoma, 915.
Gellé on chronic otorrhea, 975; on ear-vertigo, 970; on otitic facial paralysis, 967; on syphilis of the ear, 971; and Luc on mastoid abscess, 978.
Gelsemium in tetanus, 843.
General medicine, 17; paralysis, blood in, 93; etiology, 867; and idiocy, 946; vertebral puncture in, 869; surgery, 200.
Genesis of red corpuscles, 675.
Genet on anesthetics, 245.
Genital fistula, 572; tuberculosis in children, 659.
Genitalia and asthenopia, 894; and carbon dioxid, 1112; and deafness, 973.
Genitourinary diseases, 397; organs, anatomy of, 1156.
Gepner on formol, 944.
Gerhardt (C.) on bronchitis, 109; on cardiac disease, 128; on diabetes mellitus, 82; on examination of the larynx, 1020; on phenacetin-poisoning, 1132; on renal tuberculosis, 195; on rheumatism, 72.
Germ of chancroid, 1097.
Germann on glaucoma, 922.
Gerota on formalin, 1158; on lymphatics of the anus and rectum, 1148; on lymphatics of the umbilical region and bladder, 1149.
Gerrard on arteries and veins, 1148; on dextrocardia, 144.
Gerster (A. G.) on carcinoma of the rectum, 325; on malignant tumors, 254; on Rosenberg's method, 245.
Gersuny on abdominal section, 649; on conservative pelvic surgery, 654; on gall-stone operation, 321.
Gestation, ectopic, 490.
Geuer on symphysiotomy, 536.
Geyl on cervical dystocia, 519; on vaginal cyst, 561.
Gianuzzi, crescents of, 1151.
Gibney on irritable spine, 812.
Gifford on the iris, 918; on the optic nerve, 930.
Gigantism and acromegaly, 846.
Gigli on plaster-of-Paris bandages, 203.
Giglio on keratitis, 939.
Gilbert on guaiacol, 234; on vaginofixation, 611; and Fournier on hepatic cirrhosis, 782; on syphilis, 1094.
Gilchrist on blastomycetic dermatitis, 1075; on Duhring's disease, 1042; on molluscum contagiosum, 1060; on the protozoa of herpes zoster, 1038; on varicella, 1047; and Stokes on pseudolupus vulgaris, 1073.
Gilliam on transvaginal surgery, 644.
Gillespie on the stomach, 1186.
Gillette on epistaxis, 1002.
Gilpin on bitterless cascara sagrada, 1112.
Giovanni on pyrantin, 1135.
Girard on the Krag-Jorgensen rifle-wounds, 444; on parachlorophenol, 211, 1130.
Glabrificins, 726
Glaister on infanticide, 1183.
Gland, bronchial, tuberculosis of, 44; conjunctival, 1155; lacrimal, 909; in the optic nerve, 930; parotid, swelling of, 350; salivary, diseases of, 350; thyroid, 149, 968; thyroid, diseases of, 351; tuberculous, 221.
Glanders, 61, 716; -reaction, Straus's, 716.
Glandulæ parathyroideæ, 1160.
Glandular fever, 777; skin-disease, 1078.
Glass on pneumonia, 113.
Glaucoma, 921.
Gleaves on precocious motherhood, 453.
Gleet, 379.
Gleitsmann on laryngeal tuberculosis, 1027; on orthomonochlorphenol, 1130; on sinusitis, 1009.
Glenard on emetin, 1123.
Glenard's disease, 323.
Glenn (J. H.) on hemorrhage, 345; on intraarterial injection, 346.
Gley and Pachon on coagulation of the blood, 1162.
Glioma, congenital, of the orbit, 892; of the retina, 929.
Gliosarcoma of the quadrigeminal body, 993.
Glossolabiolaryngeal paralysis, 834.
Glück on wounds of veins, 342.
Glutol, 200.
Glycerol-poisoning in children, 802; acetanilid, 657; for inducing abortion, 490.
Glycogenic function of the liver, 1170.
Glycosuria, 187; in childhood, 780; and infectious diseases, 83; and ovarian cyst, 661; and the renal function, 82; from sugar, 1120; due to thread-worms, 780.
Goat's rue, 1120.

Godart-Danhieux on tetany, 839.
Goenner on the size of the fetus, 531.
Goffe on abdominal hysterectomy, 622.
Goiter, 149, 1018; and cretinism, 826; exophthalmic, 140, 352, 702, 837, 1018; among the Indians, 149; iodin in, 150; in Michigan, 149; sporadic, 150; thyroid treatment, 150, 1104.
Gold and sodium chlorid in tuberculosis, 36.
Goldberg on hematoma of the vulva, 544.
Goldberger on supernumerary mammæ, 546.
Goldener on senega-root, 1138.
Gold-foil to plug a cavity in the cerebrum, 390.
Golding-Bird (C. H.) on the curability of hernia, 277; on gastrostomy, 269; on inguinal colotomy, 310.
Goldmann on tuberculosis of the tunica vaginalis testis, 717; on tuberculous peritonitis, 275.
Goldscheider on lumbar puncture, 856, 858.
Goldschmidt on gastric digestion, 1175.
Goldthwait on tendon-transplantation, 886.
Goltz and Ewald on the spinal cord, 1178.
Gomberg on spontaneous evolution, 532.
Gomperz on cholesteatoma of the ear, 978.
Gonion on erysipelas, 50.
Gonococcus Neisser, 378, 725; in gonorrhea, 558; in pyemic abscesses, 725.
Gonorrhea, 378; eosinophile cells and, 670; and endocarditis, 681; gonococcus in, 558; Janet's treatment, 557; and metritis, 596; and pleurisy, 699; potassium permanganate in, 557; and pregnancy, 474; and sterility, 451; and stricture, 576; of the uterus, 600; in women, 556.
Gonorrheal arthritis in the newborn, 754; conjunctivitis, 914; cystitis, 556; endocervicitis, 557; endometritis, 557, 600; optic neuritis, 932; origin of acute endocarditis, 123; origin of pleurisy, 118; peritonitis, 696; rheumatism, 74; salpingitis, 474, 557; septicemia, 62; ureteritis, 556; urethritis, 556; vaginitis, 556, 557; vulvitis, 556; vulvovaginitis in children, 797.
Goodell on malignant adenoma of the uterus, 630.
Goodhart on influenza, 52.
Goris on otitic cerebral complications, 986.
Gorochow and Chlebnikow on symphysiotomy, 535.
Gossmann on albuminuria in pregnancy, 470.
Gottheil on pseudochancre, 1098.
Gottlieb on tannalbin, 1143; on thyroid, 1169.
Gottschalk on hysteropexy, 614; on metrorrhagia, 590; on stypticin, 343, 1141; and Martin's operation (uterine fibroid), 618.
Goubaroff on dystocia after ventrofixation, 522; on hysteropexy, 614.
Gouget on mitral stenosis, 130.
Goukovski (A.) on crossed hemiplegia, 836.
Gouladse on syphilis, 1095.
Gould (G. M.) on the diplopsic zone, 903: on subjective visual perceptions, 929.
Gould (J.) on bullet-wounds, 443; on cyst of the pancreas, 312.
Gouley on malignant tumors, 262.
Goullioud, case of twin pregnancy, with abortion at third month, in a double uterus, 477, 529.
Gourfinkel on retinal detachment, 928.
Gourtade on dysphagia, 151.
Gout, 79; etiology, 79; eye in, 950; guaiacum in, 81, 1122; and lead-poisoning, 80; piperazin in, 81; saturnine, 80; symptoms, 81; treatment, 81.
Gouty affections of the heart, 139.
Grabower on the vagal nucleus, 1154.
Gradenigo on adenoids, 968; on carcinoma of the mastoid, 981; on chronic otorrhea, 975; on ear-diseases, 970, 971; on otitic cerebral complication, 984.
Gradle on ametropia, 894; on functional anomalies of the eye, 901; on vernal catarrh, 915.
Graduated pressure brain-probe, 448.
Graefe on dystocia after ventrofixation, 522; on sterility, 451; on uterine prolapse, 605.
Graham on hydroa æstivale, 1044; on sprains, 372.
Grandclement on hernia of the iris, 920.
Grandin (E.) on drainage, 652; on extrauterine pregnancy, 495.
Grant (D.) on ear-diseases, 971; on nerve-deafness, 973; on otitic cerebellar abscess, 992; on purulent otitis media, 974.
Granular conjunctivitis, 915.
Granulation-tissue and infection with pathogenic microorganisms, 741.
Granuloma fungoides, 1065.
Grasemann on spontaneous evolution, 532.
Grasset on tuberculosis, 36.
Graux on paralysis of the eye-muscles, 901.
Gravel, uric-acid, 1189.
Graves' disease, 140, 352, 702, 837, 864, 1018.
Grawitz on the blood, 91.
Grayson on tetanus, 841.
Great omentum, 1150.
Greef on accommodation, 898; on myopia, 897; on the optic nerve, 930.
Green (J. O.) on astigmatism, 896; on exostoses of the ear, 960; on influenza, 1111; on otitic sinus-phlebitis, 990; on periphlebitis of the jugular, 964; on vomiting, 163.
Grethe on quinin-derivatives, 1135.
Griffin on condylomata of the trachea, 1030.
Griffith (A.) on carcinoma uteri, 632; on mitral stenosis, 131; on secondary rashes in scarlatina, 767.
Griffith (J. P. C.) on eruptions simulating scarlatina, 765; on pneumonia in children, 790; on summer diarrhea, 784.
Griffith on chancre of the eyelids, 906; osteopsathyrosis, 780; on sarcoma of the choroid, 924.
Griffiths on the hair, 1084.
Griffon on gonorrheal arthritis in the newborn, 754.
Grimberg on the colon-bacillus, 722.
Grimsdale on albuminuria in pregnancy, 470.
Grinberg on puerperal eclampsia, 518.
Griniewitch on galactagogues, 1120.
Grinnell on tetanus, 843.
Grippe, pneumonia after, 114.
Gritti's amputation, 229.
Gritzmann on malarial cachexia, 1107.
Groin, suppurative adenitis of, 217.
Gronbeck on adenoids and incontinence, 1011.
Gross (S. D.) on subhyoid pharyngotomy, 332.
Gross (S. W.) on carcinoma, 257; on pyloralgia, 164.
Grosz on alcohol in children, 801.
Groth (C. M.) on asepsis in labor, 503.
Grothan on obstetric education, 450.
Group, atropin-, 1109.
Grouven on bronchitis, 670.
Grove on test-letters, 893.
Growing pains, 876.
Growth, cardiac hypertrophy of, 787; "-fever," 33; infantile, 458; normal, of the eye, 892; of ovarian cysts, 662.
Gruber on conception in the puerperium, 511; on Ménière's disease, 969; and Durham on immunity, 726.

Grunert on cholesteatoma of the ear, 977; on surgery of the middle ear, 981.
Gryns on blood-corpuscles, 1163.
Guaiac, oil of, in the eye, 943.
Guaiacetin in tuberculosis, 38.
Guaiacol, 1121; as an anesthetic, 1122; and iodoform in tuberculosis, 38; in laryngeal tuberculosis, 1026; as a local anesthetic, 233, 1088; in malarial fever, 1121; in orchitis, 380; in pharyngitis, 996; in tuberculosis, 38, 39, 1122; in tuberculous adenitis, 1017; in typhoid fever, 771.
Guaiacum, 1122; in gout, 81, 1122; in rheumatism, 1122; in tonsillitis, 1123.
Guaita on myoma of the choroid, 924.
Gubernaculum of Hunter, 564.
Guenod on conjunctivitis, 914.
Guerard on unruptured hymen, 520.
Guérin on vaginal cyst, 560.
Guicciardi on epilepsy, 813.
Guinard on guaiacol, 1122; on neuralgia, 384.
Guinea-pigs and tuberculosis, 36.
Guinon and Bereau on pneumonia, 113.
Guiter on tuberculosis, 37.
Guitéras on the red corpuscles, 675.
Gulland on vasomotor nerves, 1166.
Gumma of the ciliary body, 919; of the cornea, 892; of the eyelid, 907; of the hypophysis, 689.
Gumprecht on the heart, 122; on leukocytes, 92.
Gunning on vaginismus, 558.
Gunshot wounds, 435; in the Transvaal, 443.
Gurlt on the statistics of anesthesia, 248.
Gurrière on chloroformization during sleep, 243.
Gusserow on malignant adenoma of the uterus, 630; and Manasse on maternal death during labor, 528.
Guttman on diphtheric conjunctivitis, 914.
Gutzwiller on extrauterine pregnancy, 496.
Guye on mouth-breathing, 1012; on nasal polypi, 1004.
Guyon on hypertrophy of the prostate, 407; on sterilization of catheters, 206.
Gymnastics in cardiac disease, 135.
Gynecology, 550.
Gynecomastia, 1159.
Gyromele, 155.

Haas on burns, 417.
Habit, cigaret, and laryngitis, 1021; cocain, 997; invalid, 551.
Habitual abortion, 488.
Haenel on the disinfection of wounds, 201; on tuberculosis of the ear, 976.
Haffkine on cholera, 57, 731.
Hahn on bullet wounds of the skull, 448; on splenectomy, 314.
Haig on guaiacum, 1123; on lithemia, 1137.
Haig's chemic theory, 79.
Haines on dextrocardia, 144.
Haines's method, 580.
Hair, change of color of, 1084; diseases of, 1084.
Hairy granulation-tumor of the middle ear, 960.
Halberstadt on eye-strain, 894.
Haldane on carbonic-oxid-poisoning, 1178.
Hall (G. C.) on amputation of the arm, 231; on extrauterine pregnancy, 494; on iron, 1174.
Hallevoorden on speech-anomaly, 849.
Halliburton on coagulation of the blood, 1161.
Hallion on vasomotors, 1167.
Hallopeau on cutaneous tuberculosis, 1040; on Duhring's disease, 1041; and Jeanselme on ichthyosis, 1060.
Halsted on appendicitis, 289; on carcinoma of the breast, 256; on catgut, 208.
Hamburg on albumose-milk, 779.
Hamburger on salivary digestion, 157.
Hamburger's method, 739.
Hamill (R.) on vaginal atresia, 566.
Hamill (S. M.) on renal tuberculosis, 195, 798.
Hamilton on anerobic bacteria, 738; and Embryos-Jones on diphtheric conjunctivitis, 914.
Hammer on the gonococcus, 725.
Hammond on multiple neuritis, 795.
Hance on creasote, 37; on tuberculosis, 32.
Hand, cleft-, 887; diseases of, 887.
Hand (A.) on coexistence of infectious diseases, 754; on retropharyngeal abscess, 788, 1017.
Handfield-Jones on the heart in labor, 507; on the heart in pregnancy, 454; on tuboabdominal pregnancy, 499; on valvular cardiac disease in pregnancy, 469.
Handmann on kosotoxin, 1126.
Hanot on diabetes mellitus, 85; on pulmonary stenosis, 132; on tuberculosis, 37; and Letienne on gall-stone, 181; and Levi on tuberculosis, 43.
Hansell on advancement, 903; on the eye, 901; on eyeglasses, 899; on foreign bodies in the eye, 953; on hyperopia, 904; on optic atrophy, 950; on retinitis pigmentosa, 927; on tumor of the iris, 920.
Hansemann on Addison's disease, 104; on endothelioma, 704; on false diverticula of the intestine, 692; on gastric tumors, 692; on lumbar puncture, 859; on the pulmonary alveoli, 1156; on the specificity of bacteria, 711.
Harbitz on atypical croupous pneumonia, 697.
Hardon on fibromyoma in pregnancy, 480.
Hare (H. A.) on bromism, 1111; on epileptoid fits, 817; on fever, 68; on hysteric spasm of the trunk-muscles, 810; on pernicious anemia, 99.
Hare-lip, 350.
Harlan (H.) on tumor of the eyelid, 907; and DeSchweinitz on ectropion of the eyelids, 892.
Harley on muscular energy, 1172; on obstruction of the pancreatic duct, 184; on uric-acid gravel, 1189.
Harnack on erythrophleum, 1117.
Harnisch on x-rays in ophthalmology, 954.
Harrell on foreign bodies in the nose, 1006.
Harris (E. A.) on albumosuria, 190, 699; on the diagnosis of pregnancy, 458.
Harrison on hernia in children, 281; on hypertrophy of the prostate, 410; on puerperal eclampsia, 514; on sounding, 406.
Harsant on exophthalmic goiter, 353.
Harte on epiphyseal separation, 358.
Hartley on dermoid tumor, 252; on tetanus, 841.
Hartmann on acute otitis media, 966; on dysbasia hysterica, 974; on ear-surgery, 982; on leukemia, 314; and Toupet on abortion, 488; on syphilitic stricture of the rectum, 327.
Hartzell on agminate folliculitis, 1080; on the protozoa of herpes zoster, 1038; on recurrent scarlatinoid erythema, 1032.
Hasenbalg on vaginal fibroma, 562.
Haskin on Cesarean section, 537.
Hastings on cystic degeneration of the chorion, 462.
Hauck on abdominal section, 649.
Haug on influenza-otitis, 963; on the middle ear, 962; on otitic sinus-phlebitis, 991.
Haultain on abortion, 485.
Haushalter on gonorrheal arthritis in the new-born, 754; on tuberculosis in children, 775.
Haven (G.) on Cesarean section, 536; on kynocephalus, 468.
Hawkins on rheumatism, 74.

Hawthorne on gastric ulcer, 166.
Hay fever, 999, 1001.
Hayden on suppurative adenitis of the groin, 217.
Hayem on the blood, 91; on dilatation of the stomach, 164; serum, 218.
Hayes (P. J.) on aneurysm, 340; on hydrophobia, 61; on intestinal anastomosis, 296.
Haynes (F. L. and J. R.) on acetanilid, 657; on hemiplegia in typhoid fever, 835.
Head of the pancreas, carcinoma of, 343; superficial nerves of, 1153.
Headache from ametropia, 893.
Head-injuries, blindness after, 934.
Hearder on paraldehyd in asthma, 1130.
Hearing, 1181; in congenital atresia of the auditory canal, 961.
Hearn (J.) on fractures, 358; on hernia, 282.
Heart, 1167; and anesthetics, 248; aneurysm of, 146; arrhythmia of, 139; -disease in children, 127; congenital, 144; functional, in women; 552; and pregnancy, 127; diseases of, 122; examination of, 122; gouty affections of, 139; in labor, 507; nonvalvular affections of, 133; in pregnancy, 454; rupture of, 145; syphilis of, 146; third coronary artery of, 1148; thrombosis of, 680; transposition of, 144; tuberculosis of, 678; ulcer of, 146.
Heat, animal, 1172; dry, in joint-disease, 879.
Heath (C.) on hare-lip, 350.
Heaton on rupture of the bladder, 401.
Hebir on cholera, 57.
Heckel on foreign bodies in the eye, 952.
Heddaeus on diplococcus-strumitis, 703.
Hedin on blood-corpuscles, 1163.
Hedlicka on general paresis, 871.
Heffron on tuberculosis, 31.
Heidenhain on absorption from serous spaces, 1166; on arterial suture, 343.
Height of the fundus uteri in labor, 505.
Heiman on the gonococcus Neisser, 378; on otitic cerebellar abscess, 993; on twin pregnancy, 529.
Heineke-Mikulicz operation, 268.
Heinricius on puerperal sepsis, 541.
Heinzel on amblyopia, 932.
Heitler on mitral regurgitation, 132; on pseudodiastolic murmurs, 131.
Hektoen on carcinoma of the ureter, 700; on gumma of the hypophysis, 689; on tuberculous meningitis, 687.
Helix, lymphangioma of, 958.
Heller on bile-forming cancer-nodules in the lung, 704; on pharyngotherapy, 1016; on the skin, 1158; on thrush, 690.
Hellgren on trachoma, 915.
Helme on adenoids, 968, 1011; on the kidney, 1156; on suppurative adenitis, 217.
Hematemesis, 167.
Hematic cyst of the vagina, 562.
Hematocele and extrauterine pregnancy, 492; pelvic, after labor, 544.
Hematogenous jaundice, 693.
Hematologic studies, 668.
Hematoma, pelvic, after abdominal section, 656; of the vulva, 544.
Hematoporphyrin, 1191.
Hematotympanum, 962.
Hematuria, 55.
Hemeralopia, 923.
Hemianopsia in otitic cerebral abscess, 992.
Hemihypertrophy, 745.
Hemiplegia, collateral (uncrossed), 833; crossed, 836; homolateral, 833; in pertussis, 773; in typhoid fever, 834.
Hemoglobin, estimation of, 90; in neurotic disorders, 93; -percentage of the blood, 673; in the urine, 190.
Hemoglobinometer, Fleischl's, 90.
Hemoglobinuria, 55; idiopathic, 190.
Hemoglobinuric fever, 56.
Hemokonia, 671.
Hemolysis, 93.
Hemophilia, 106; calcium chlorid in, 106.
Hemoptysis in typhoid fever, 22.
Hemorrhage, 343; accidental, 483; from the antrum, 1009; asaprol in, 801; into the conjunctiva, 917; into the drum-cavity, 962; Esmarch bandage in, 344; during Estländer's operation, 343; after extraction of a tooth, 344; in extrauterine pregnancy, 491; gastrointestinal, 178; internal, 431; intestinal enemata in, 344; from the lung, 329; pharyngeal, 1016; in placenta prævia, 484; postclimacteric, 631; postpartum, 544; retinal, 926; from the skin, 1057; transfusion in, 345; in tuberculosis, 34; uterine, 588; in uterine fibroids, 616; vesical, 399; vitreous, 929.
Hemorrhagic nephritis, 192; in typhoid fever, 21; purpura, bacillus of, 715.
Hemorrhoids, treatment of, 326.
Hemostasis, permanent, 432; temporary, 430.
Hemostatic, stypticin as a, 343.
Hemothorax, 327.
Henggeler on strangulated hernia, 282.
Hengst on acute otitis media, 962.
Hennebert on epithelioma of the ear, 958.
Hennig on influenza, 51.
Hennig's sphincter, 658, 659.
Henrotin on conservative pelvic surgery, 654; on transvaginal surgery, 644.
Henry (F. P.) on chlorosis, 96; on chyluria, 198, 678; on pernicious anemia, 99; on the photometer, 935; on the pupillometer, 919; on rheumatism, 73; on tubal pregnancy, 494.
Henshaw on typhoid fever, 29.
Hepatic abscess, 179; after dysentery, 59; statistics of, 315; in typhoid fever, 23; artery, aneurysm of, 181; cirrhosis in children, 782; colic, 182; disease, 174, 175; duct, congenital atresia of, 782.
Hepburn on the digits, 1158; on general paralysis and idiocy, 946; on a third coronary artery, 1148.
Hereditary ataxia, eye in, 947; transmission of ovarian cysts, 662.
Heredity of acquired immunity, 727; and alcholism, 865; in carcinoma of the heart, 261; and twins, 530; in tuberculosis, 33.
Héricourt and Richet on carcinoma, 735; on syphilis, 1095.
Herman on inversion of the uterus, 527; on phlegmasia alba dolens, 541; on stricture of the female urethra, 576.
Hermaphroditism, 564.
Hermes on abscess of the liver, 315.
Hernia, 277; after abdominal section, 278; in children, 280; curability of, 277; femoral, 286; imbrication method, 284; inguinal, 286; of the iris, 920; lap-joint, method in, 284; nonabsorbable sutures in, 284; obturator, 279; of the ovary, 664; radical cure of, 284; strangulated, in children, 282; and taxis, 279; tuberculosis of, 220; ventral, after abdominal section, 656.
Hernial fluid, bacteriology of, 278.
Herpes pudendalis, 554; zoster, camphor in, 1037; nerve-lesions in, 1038; protozoa of, 1038.
Herrick on pernicious anemia, 98; on polymyositis, 75.
Herschell on cardiac disease, 136.
Herskin on exophthalmic goiter, 352.
Herter and Smith on intestinal putrefaction, 172.

Hertfeld and Hermann on the capsule-bacillus, 715.
Hertoghe on myxedema, 89.
Heryng on laryngeal tuberculosis, 1027.
Hess on cataract, 935; on corneal astigmatism, 895.
Hessler on acute otitis media, 965; on otogenous pyemia, 990.
Heterophoria, 903.
Heterotropia, 903.
Hetzig on locomotor ataxia, 851.
Heubner on cow's milk, 746; on diphtheria, 759; on meningitis, 793.
Heuse on corneal ulcer, 940.
Heusser on actinomycosis, 115, 698.
Huessner (M. L.) on hyperidrosis, 1084; on suture of the gall-ducts, 319.
Hewetson on tuberculosis, 40.
Hexamethylenetetramin, 1145.
Heydenreich on the operative treatment of fractures, 357.
Heyl on hemeralopia, 924; on rupture of the choroid, 925.
Hiccough, 822; fetal, 464; sulfonal in, 1142.
Highet on optic neuritis, 932.
Hilbert on amblyopia, 931; on diphtheria, 757; on foreign bodies in the eye, 951.
Hill (L.) on anesthesia, 249; on bacteria, 711.
Hills on lithemia, 78.
Himmelsbach on inversion of the uterus, 526; on typhoid fever, 24.
Hind (A. E.) on hemorrhage, 344.
Hindenburg on leukemia, 101.
Hink on fetal hiccough, 464.
Hinsdale (G.) on tuberculosis, 31.
Hinselwood on word-blindness, 949.
Hip, ankylosis of, 880; bloodless reduction of, 879; congenital dislocation of, 373, 879; diseases of, 879; dislocation of, reduction of, 880; spontaneous dislocation of, 372.
Hip-disease, deformity in, 881.
Hip-joint amputation, 232; and atmospheric pressure, 881.
Hip-splint, 882.
Hirsch and Edel on phenylhydroxylamin-poisoning, 1132.
Hirschberg on foreign bodies in the eye, 952; on ocular parasites, 918; on syphilitic retinitis, 928.
Hirschfeld on acetonuria, 188.
Hirschl on general paralysis, 867.
Hirst (B. C.) on Cesarean section, 537; on dermoid cyst in pregnancy, 479; on fœtus amorphus, 467; on hysterectomy in puerperal sepsis, 644; on myoma of the ovarian ligament, 664; on inversion of the uterus, 526; on supernumerary mammæ, 546; on vaginal atresia, 566; on valvular cardiac disease in pregnancy, 470; on symphysiotomy, 535.
His on anatomic nomenclature, 1147; on the ear, 1154.
Hislop on cut-throat, 332.
Hitzig on influenza, 52.
Hoadley on the spinal brace, 875.
Hobbs on pelvic disease and mental disorders, 552.
Hodara on freezing, 1044; on gleet, 379; on plasma-cells, 1160.
Hodenpyl on tuberculosis, 36.
Hodgkin's disease, 103.
Hodgkinson on the laryngeal ventricles, 1021; on the vocal bands, 1029.
Höck on vegetable milk, 749.
Högerstedt on cardiac disease, 136.
Hoene on foreign body in the orbit, 913.
Hoepfl on cornual pregnancy, 497.
Hösslin on exophthalmic goiter, 838.
Hoffa on congenital dislocation of the hip, 879; -Lorenz operation, 879.
Hoffa's operation, 374.
Hoffmann on postmortem Cesarean section, 528; on synovitis of the knee, 882.
Hofmeier on extrauterine pregnancy, 492; on ichthyosis uteri, 626; on malignant adenoma of the uterus, 630; on uterine fibroids, 621.
Hogg on bicycling for women, 584.
Holanhena antidysenterica in dysentery, 58.
Holinger on acute otitis media, 965.
Holladay on tuberculosis, 33.
Holmes (T. K.) on abdominal section, 306; on hysterectomy in puerperal sepsis, 643; on puerperal eclampsia, 514; on sporadic goiter, 150.
Holt on acute otitis, 964; on cardiac anomalies, 786; on foreign bodies in the eye, 952; on inanition fever, 547, 751; on mastoiditis, 979; on pneumonia in children, 790.
Holth on ocular syphilis, 947; on salicylic acid, 944.
Holz on ectropion, 908; on hemorrhagic nephritis, 192; on shock, 798; on typhoid fever, 718; and Lydston on the eye, 902.
Homans on dermoid cyst in pregnancy, 479.
Homem on malarial fever, 54.
Homicide without external marks of violence, 1184.
Homolateral hemiplegia, 833; pyramidal fibers, 1179.
Hoor on nosophen, 944.
Hope on tonsillitis, 1014.
Hoppe on the eye, 953; -Seyler on gastric carcinoma, 168; on the Röntgen rays, 199; on the stomach, 153.
Horbaczewski on uric acid, 1137; on urinary calculi, 1190.
Horny growths of the eyelid, 907.
Horse-nettle in epilepsy, 814.
Horsh on ophthalmia neonatorum, 913; on the retina, 925; on subconjunctival injections, 942.
Horsley on laminectomy, 396; on leontiasis ossium, 388.
Hospital, field-, 435.
Hotchkiss on typhoid fever, 28, 294.
"Hot eye," 950.
Houdart on choroiditis, 924.
Hour-glass contraction of the stomach, 167, 272.
Houston's creases, 305.
Huber on the Röntgen rays, 199; on the sympathetic nerves, 1181.
Hubbell on nuclear ophthalmoplegia, 905.
Huchard on benzonaphtol, 1110; on cardiac disease, 138; on cardiac hypertrophy, 787; on edema of the lungs, 114; on hysteric pseudo-meningitis, 806; on thyroid extract, 89; on uremia, 194.
Hufschmid on aneurysm of the vertebral artery, 341.
Hughes on endemic fever, 64.
Huguier on cyst of the vagina, 560.
Human milk, 510; casein in, 510; gases in, 511.
Humerus, congenital dislocation of, 373; supracondyloid process of, 1148.
Humiston on thirst after abdominal section, 658.
Humphries on rheumatism, 69.
Hundley on tubal pregnancy, 493; on uterine prolapse in pregnancy, 475.
Hunsberger on neuralgia, 818.
Hunt on lithiasis, 798; on pernicious anemia, 99; on vasomotors, 1167.
Hunter on Cesarean section, 536; on chlorosis, 96; gubernaculum of, 564; on jaundice, 694; on pernicious anemia, 674.
Hurley on malarial fever, 52.
Hutchinson (J.) on erosion of the auricle, 958; on the eye in gout, 950; on gigantism, 847; on morphœa herpetiformis, 1062; on symmetric acrosphacelus, 1056; on thyroantitoxin, 1105.
Hyaloid artery, persistent, 892.
Hydatid cysts of the liver, 180; disease of the spleen, 314.
Hydatidiform mole, 462.
Hyde and Senn on Madura foot, 1055.
Hydroa æstivale, 1044.

Hydrobromic acid in quinin-amblyopia, 931.
Hydrocele, excision of the sac, 408; iodin injections for, 407; of the labium majus, 564.
Hydrocephalus, 791; fetal, 792.
Hydrochloric acid in bone-diseases, 879; determination of, 153; in disease of the tonsils, 1015; in gastric juice, 153; of the stomach, 1186.
Hydrogen dioxid in epistaxis, 1002.
Hydrophobia, 61.
Hydrophthalmus, 893.
Hydrops tubæ profluens, 658.
Hydrosalpinx, 658; follicularis, 658; simplex, 658.
Hydrotherapy in gouty heart-disease, 140.
Hydroxylamin hydrochlorate, 1123.
Hygiene, 1183; of the kidney, 1188; of pregnancy, 459.
Hymen, unruptured, and pregnancy, 520.
Hyoid, fracture of, 1019.
Hyoscin hydrobromate in alcoholism, 823.
Hyoscin, 1109.
Hyoscyamin, 1109.
Hyperidrosis, 1084.
Hyperinvolution of the uterus, 510.
Hyperopia, 904; latent, 893.
Hyperpyrexia, puerperal, 540; in tuberculosis, 39.
Hyperpyrexial malarial fever, 54.
Hypersecretion of gastric juice, 161.
Hyperthyroidation, 837.
Hypertrophic cirrhosis of the liver, 178; osteoarthropathy, pulmonary, 845; rhinitis, 999.
Hypertrophy of the heart, 546; cardiac, of growth, 787; congenital, of the colon, 786; idiopathic cardiac, 133; polypoid, of the tonsils, 1015; of the prostate, castration for, 406, 408, 410; ligation of the iliac arteries for, 407; ligation of the vasa deferentia for, 407; of the skin, 1060; of the spleen in malaria, 54.
Hypes on Pelzer's method, 490.
Hyphomycetic skin-disease, 1081.
Hypnotic confessions, 1184.
Hypnotism, mydriasis cured by, 813.
Hypobromite or hypochlorite method of estimating urea, 1194.
Hypodermic injections of mercury in syphilis, 1096; use of iron, 95.
Hypoglossal nerve, 1153.
Hypoleukocytosis in acute tuberculosis, 672.
Hypophysis, gumma of, 689.
Hypopyon, 940.
Hypoxanthin, 1195.
Hysterectomy, abdominal, 621; infection in, 637; in puerperal sepsis, 642; for suppurative diseases of the pelvic viscera, 641; vaginal, 620, 636; fistula after, 573.
Hysteria in children, 796, 810; diagnosis, 805; eye in, 945; and retinal tire, 925; and tetany, 810.
Hysteric anorexia, 811, 812; aphonia, 807, 974, 1027; breast, 811; contractures, 807; deafness, 974; eye-symptoms, 807; mastoiditis, 981; pseudomeningitis, 806; spasm of the trunk-muscles, 809; vomiting, 811; vomiting of blood, 166.
Hysteroneuroses, 819.
Hysteropexy, 613; dystocia after, 614; pulmonary infarction after, 613.
Hysterorrhaphy, 615.
Hystero-traumatic aphonia, 1028.

Iceland, leprosy in, 1070.
Ichthyol in anal fissure, 327; in blepharitis, 944; in burns, 416; in eczema, 1035; in erysipelas, 212, 1047; injections in tuberculosis, 39; in scarlatina, 769; in vulvitis, 554.
Ichthyosis congenita, 549, 1060; simulating scleroderma, 1060; uteri, 624.
Icing-liver, 695.
Icterus neonatorum, 549, 752.
Ictus, laryngeal, 1029.
Idanof on puerperal insanity, 472.
Idiocy, craniectomy for, 391, 867; family form of, 867; and general paralysis, 946.
Idiopathic cardiac hypertrophy, 133; hemoglobinuria, 190; osteopsathyrosis, 780; purpura, 1057.
Igniextirpation of the uterus, 637.
Iliac arteries, ligation of, for prostatic hypertrophy, 407; colostomy, 310; veins, thrombosis of, in typhoid fever, 23.
Ill (E. J.) on lateral displacement of the uterus, 604.
Illumination in gastric disease, 155.
Iliofemoral aneurysm, 340; pelvis, 514.
Imbrication method in hernia, 284.
Imlach on puerperal sepsis, 542.
Immediate suture of gall-ducts, 319.
Immobilization of joints and limbs, 434.
Immune animals, blood of, 728.
Immunity, 726; acquired, heredity of, 727; and alkalinity, 727; to variola, 47.
Immunization against cholera, 730; in diphtheria, 763; forced, 729.
Impacted fracture of the neck of the femur, 362.
Impaction of the fetal shoulders, 532.
Impetigo contagiosa annulata et serpiginosa, 1037.
Implantation dermoid tumor of the cranial cavity, 252; of the ureter into the bladder, 412; of the ureter into the intestines, 412.
Impregnation, 452.
Inanition fever in the newborn, 547, 751.
Incipient phthisis, 34.
Incision in appendicitis, 291; in otitis media, 967; of the pericardium, 338.
Incontinence and adenoids, 1011; cystic, in locomotor ataxia, 851; nocturnal, 831; of urine, 576.
Incoordination of the centers, 904.
Increase of weight of premature infants, 745.
India, Haffkine's cholera immunization in, 731.
Indians, goiter among, 149.
Indican in the gastric juice, 154.
Indicanuria, 172.
Indications for inducing abortion, 489.
Indovini on glaucoma, 923.
Induction of abortion, 489; of labor in puerperal eclampsia, 519.
Indurated pseudochancres, 380.
Infancy, bile in, 745; otitis media in, 963; physiology of, 745; psoriasis vulgaris in, 1036; tuberculosis in, 33.
Infant, atrophic kidneys in, 700; -feeding, 745; premature, weight of, 745.
Infanticide, 1183.
Infantile eclampsia, 515; growth, 458; intussusception, 784; myxedema, 781; paralysis, 794; syphilis, 1088; tetany, 839; uterus, 510.
Infarction, pulmonary, after hysteropexy, 613.
Infection, 67; aspergillus-, 115; in hysterectomy, 637; intestinal, 172; local, of the ear, 960; of the orbit, 910; of ovarian cysts, 662; polymicrobic, 742; protozoan, of the skin, 1076; secondary, after acute otitis media, 965.
Infectious angeiocholitis, 322; cholecystitis, 322; disease, 18, 754; acute, of bone, 884; acute, and leukemia, 677; coexistence of, 754; and glycosuria, 83; and pregnancy, 473; spleen in, 703; surgical, 742; fevers, circulatory disturbances in, 138; origin of chlorosis, 587.
Infective osteitis and arthritis, 370.
Infiltration-anesthesia, 235, 908.
Inflammation, acute, of the lingual tonsil, 1013; of bone, 369; fibrinoid degeneration of connective tissue in, 741; and fibrosis, 740; of the pla-

centa, 459: septic, of the throat, 1013; traumatic, of the semilunar cartilages, 377; uterine, 595.
Inflation in labyrinthine deafness, 971.
Influence of castration on the uterus, 640.
Influenza, 51, 723, 1002; complications and sequels, 51; ear in, 969; and endometritis, 599; orbital cellulitis in, 911; -otitis, 963; Pfeiffer's bacillus in, 51; pneumonia in, 52, 114; prophylaxis of, 52; quinin in, 52; throat-affections of, 51; thrombosis of the veins in, 52; and typhoid fever, 52.
Infundibulopelvic ligament, 1152.
Infusoria in malaria, 1136; and quinin-derivatives, 1135.
Ingals on ametropia, 893; on cervical tuberculous adenitis, 1017; on transillumination of the antrum, 1008; and Ohls on desiccated thyroids, 1018.
Ingraham on cocain-poisoning, 1114; on tubal pregnancy, 494; on tuberculosis, 36.
Ingria on calculous pyelitis, 194.
Inguinal colotomy, skin-bridging for, 310; hernia, 286.
Inhalation of oxygen in anemia, 95; -pneumonia, 250.
Inherited syphilis, contagiousness of, 1089.
Injection of albumoses, leukocytosis after, 92; intraarterial, 346; subconjunctival, 941; subcutaneous, of fat, 1119.
Injuries of the eyeball, 951; of joints, 371; of the lung, 329; to the tendons of fingers, 355; of the thoracic duct, 348; of the thumb, 374.
Innominate artery, ligature of, 341.
Insane, breaking-strain of the ribs in, 864.
Insanity, puerperal, 471; thyroid-feeding in, 869; traumatic, 387.
Insects and *x*-rays, 1182.
Insomnia, 832.
Inspired air, microorganisms in, 713.
Instrument-cases, obstetric, 451.
Insufficiency of convergence, 901, 903.
Insufflation for asphyxia, 1030.
Intercostal muscles, 1178.
Intermenstrual dysmenorrhea, 591.
Intermittent fever in the puerperium, 540; siphonage of the bladder, 399.
Internal hemorrhage, 431; secretion, 1168.
Interstitial extrauterine pregnancy, 497; keratitis, 939.
Intestinal anastomosis, 295; anthrax, 60, 173; antisepsis, 173; in chlorosis, 97; antiseptics in summer diarrhea, 784; atony, 168, 169; bacteria, in the newborn, 750; concretions, 171; digestion, 1176; infection, 172; infection in tuberculosis, 44; invagination, 309; irrigation in summer diarrhea, 783; obstruction, 169, 302; due to occupation, 303; postoperative, 303, 655; parasites in children, 786; perforation, resection for, 301; in typhoid fever, 28; putrefaction, 172; tract, amebic catarrh of, 59; tuberculosis in children, 775; wall and bacteria, 712.
Intestines, bacteria in, 172; diseases of, 168, 292; false diverticula of, 692; flagellate protozoa in, 743; implantation of the ureter into, 412; microorganisms in, 172; multiple gunshot wounds of, 445; pathogenic anaerobic bacillus of, 714; perforation of, by a polyp, 693; perforation of, in typhoid fever, 292.
Intraabdominal carcinoma, supraclavicular adenopathy in, 307; pressure in enteroptosis, 159.
Intraarterial injection, 346.
Intracranial neuritis, 933; tumors, eye in, 948.
Intractable vomiting, 163, 269.
Intragastric pressure, 156.
Intranasal applications, 996; disease and deafness, 1003; melancholia from, 1003.
Intraperitoneal rupture of the bladder, 400; suprapubic lithotomy, 404; vaginofixation, 613.
Intrathoracic tumors, 120, 704.
Intratympanic surgery, 972.
Intrauterine amputation, 461: fractures, 466; transmission of immunity from vaccinia, 49; of typhoid infection, 18; typhoid fever, 771.
Intravenous injections of mercuric chlorid, 1097; in puerperal sepsis, 542.
Intubation, 1023, 1028.
Intussusception, infantile, 784; abdominal section for, 309; statistics of, 310.
Invagination, intestinal, 309.
Invalid habit, 551.
Inversion in asphyxia neonatorum, 547; of the uterus, 526.
Involuntary opening of the lateral sinus, 981.
Involution after labor, 509.
Involvement of the skin in mammary carcinoma, 261.
Inward rotation in club-foot, 885.
Iodic eruption, 1051.
Iodids in syphilis, 1097.
Iodin in goiter, 150; in gonorrheal endocervicitis, 557; -injections for hydrocele, 407; -liniment, skin-disease from, 1053; in trachoma, 915.
Iodoform-gauze, 206; -glycerol in tuberculous osteomyelitis, 878; ointment in suppurative adenitis, 217; in tuberculosis of the ear, 976; in tuberculous abscesses, 877; in tuberculous laryngitis, 1026.
Iodoformin, 1123.
Iodol in diabetes mellitus, 86; in eye-diseases, 944.
Ipecacuanha alkaloids, 1123.
Iridectomy in glaucoma, 923: malignant tendency after, 923.
Iridocyclitis, 919.
Iris, absence of, 892; carcinoma of, 920; as a diaphragm and photostat, 896; diseases of, 918; functional diseases of, 918; hernia of, 920; -reaction, 918; rupture of, 920; tumor of, 920.
Irish on vaginal hysterectomy, 620.
Iritis, acute plastic, 919.
Iron, 1125, 1174; absorption and elimination of, 94; in anemia, 1125; in chlorosis, 96, 97; in exophthalmic goiter, 143; hypodermic use of, 95; in purulent otitis media, 974.
Irrigation in endometritis, 601; intestinal, in summer diarrhea, 783; in purulent ophthalmia, 913.
Irritability, muscular, in pneumonia, 111.
Irritable bladder, 576; spine, 812.
Ischiopagus, 751.
Isnardi on ligation of the vasa deferentia, 407; on tuberculosis, 221.
Israel (I.) on primary multiple carcinoma, 704; on tuberculous peritonitis, 277; on wounds of veins, 343.
Itching, 1059.
Izal, 1126.

Jaccoud on tuberculosis, 32.
Jack on ocular palsy, 905.
Jack-stone in the esophagus, 426.
Jackson (E.) on mydriatics, 943; on retinoscopy, 895; and Schneideman on wound of the crystalline lens, 952.
Jackson (S.) on cardiac disease, 127; on convulsions from lead and alcohol, 849; on the prismometer, 956.
Jacksonian epilepsy, 388.
Jacobi (A.) on absence of the uterus, 595; on ischiopagus, 751; on lumbar puncture, 856; on nephritis in the newborn, 548, 798; on patent ventricular septum, 144; and Tynberg (S.) on pygopagus, 467, 751.
Jacobi (M. P.) on ocular palsy, 905.

Jacobs (C.) on vaginal hysterectomy, 636, 644; on vaginofixation, 611.
Jacobsohn on arteriosclerosis, 833.
Jacobson on Carden's amputation, 230; on excision of the rectum, 326; on laryngotomy, 332; organ of, 1154.
Jacquinet on cardiac syphilis, 146.
Jacquot on puerperal sepsis, 542.
Jacub on threatened abortion, 488.
Jacubowitsch on the bile in childhood, 745.
Jaesche on trachoma, 915.
Jahreiss on ovarian cyst, 660.
Jakob on leukocytes, 92.
James on diabetes mellitus, 84.
Jamieson (W. A.) on skin-diseases, 1087.
Janet on the eye in hysteria, 946; on hysteric spasm of the trunk-muscles, 809.
Janet's treatment of gonorrhea, 557.
Janeway on bromic poisoning, 1111; on marrow-extract, 1107; on neuralgia, 818.
Jankelowitz on the pancreas, 1151.
Jansen on optic aphasia, 949; on otitic cerebral complications, 987; on otitic sinus-phlebitis, 990.
Januszkiewicz on optic neuritis, 932.
Jardine on labor, 502.
Jarman on retrocession of the uterus, 606.
Jastrowitz on the Röntgen rays, 424.
Jaundice, 175; blood in, 176; catarrhal, 175; hematogenous, 693; in the newborn, 549; pathology of, 694; due to pressure, 176; and syphilis, 175; from toluylendiamin, 693; and tuberculosis, 176.
Javanese pelvis, 453.
Jaworski on steam as a hemostatic, 211; and Nencki on anthrax, 60.
Jeannel on fever, 68.
Jeffé on induction of abortion, 489.
Jenches on lupus erythematosus, 1070.
Jenks on extrauterine pregnancy, 495.
Jennings (C.) on albinism, 918; on fever, 68; on hemorrhage, 345.
Jessup on ametropia, 893; on keratitis, 939; on retinal detachment, 928.
Jetter on ovarian tumors in pregnancy, 479.
Jewett on symphysiotomy, 534.
Jéz on apolysin, 1108.
Joachimsthal on deformities, 1159.
Joch on purulent leptomeningitis, 964.
Jocqs on orbital tumors, 911; on pseudomembranous conjunctivitis, 916; and Fourgs on foreign body in the eye, 952.
Joffroy on jaundice, 176.
Joffroy's symptom, 141.
Johannessen on the diphtheria antitoxic serum, 732.
Johns Hopkins Hospital statistics, 27.
Johnson on cholera, 57; on esophageal stenosis, 151; on amblyopia, 900; on amblyopia exanopsia, 926.
Johnson (F. W.) on tubal pregnancy, 494.
Johnson (H. L. E.) on the menopause, 593.
Johnson (J. T.) on abdominal hysterectomy, 622; on Battey's operation, 618.
Johnson (R.) on swelling of the parotid gland, 350.
Johnston on congenital chorea, 794; on xanthoma diabeticorum, 1064; on Walcher's position, 534.
Joint-disease, chronic, 878; dry heat in, 879; syphilitic, 776; -lesions of scarlet fever, 376; -tuberculosis, 375, 884.
Joints, ankylosis of, 377; auscultation of, 377; diseases of, 371; loose bodies in, 884; immobilization of, 434; injuries of, 371.
Jolles (A.) on bile-pigment, 1191; on glycosuria, 1192; on soap-solution, 1186; on test for albumin, 1191.
Jolly on myasthenia gravis pseudoparalytica, 947.
Jonas on extrauterine pregnancy, 495.
Jones on ametropia, 894.
Jones on diabetes mellitus, 87; on prolapse of the laryngeal ventricle, 1021; on the $\bar{x}$-rays, 426.
Jones (M.) on dysmenorrhea, 592.
Jones (S. S.) on puerperal eclampsia, 514, 517; and Platt on carcinoma of the breast, 258.
Jonnesco on tuberculosis of hernia, 220.
Jordan on intestinal obstruction, 169; on tuberculous peritonitis, 277.
Jores on formalin, 738.
Josias on scarlatina, 767.
Joubert on menstruation, 586.
Jouin on the menopause, 592.
Jourdan on choledochotomy, 316.
Judd on luxation erecta of the shoulder-joint, 374.
Judson on deformity in hip-disease, 881.
Jugular, periphlebitis of, 964.
Juice, gastric, 1175.
Jullien on chancroid, 1098; and Descouleurs on scabies, 1049.
Juniper oil for sterilizing catgut, 207.
Jurisprudence, medical, 1183.
Juvenile paresis, 868.
Juxtaarticular tuberculous ostitis, 881.

KAAN on abdominal pregnancy, 499.
Kaes on the brain, 1154.
Kahane on blastomycetes, 708; on carcinoma, 707.
Kahn on abdominal section, 650; on missed labor, 482; on twin pregnancy, 529.
Kalt on purulent ophthalmia, 913.
Kammerer on carcinoma of the rectum, 326.
Kane on asbestos as a surgical dressing, 201.
Kangaroo tendon, 203.
Kanthack on infectious diseases, 703; on laryngeal ulcers, 1022; on papilloma of the larynx, 1024; and Stephens on culture-media, 736.
Karewski on arthrodesis, 887.
Kashmir, leprosy in, 1069.
Kast on fever, 67; on leukemia, 101.
Katatonia, 866.
Katz on cataract, 936; on membranous rhinitis, 1000; on presbyopia, 899.
Katzenstein on pseudoleukemia, 103.
Kaufmann on animal heat, 1172; on the liver, 1171; on muscular energy, 1171.
Kaurin on leprosy, 59.
Kayser on cataract, 938.
Kebbell on hysteric aphonia, 807.
Keber on gumma of the eyelid, 907.
Keefe on anesthetics, 248.
Keegan on rhinoplasty, 1008.
Keen (W. W.) on fracture of the patella, 366; on neuralgia, 385; on the Röntgen rays, 421; on thyroid operations, 351; on transfusion of blood, 225; on traumatism of the kidney, 413.
Keetley on the shoulder-brace, 875.
Kehr on gall-stones, 320.
Kehrer on neglected shoulder-presentation, 532.
Keilmann on fat-milk, 747.
Keith's lithotrity, 405.
Kelley (A. O. J.) on tonsillitis, 1014.
Kelley (J. T.) on fibromyoma in pregnancy, 480.
Kellgren and Colombo on absorption, 1166.
Kelling on periodic vomiting, 161.
Kellock on pleurisy, 118.
Kellock's sign, 118.
Kelly (H. A.) on anastomosis of the ureter into the bladder, 411; on catgut, 207; on cystoscopy, 578; on hysterectomy, 619; on hysteropexy, 614; on Pawlik's method, 581; on renal calculus, 410, 582; on ureterovaginal fistula,

573; on urethroureteral anastomosis, 574.
Keloid, cicatricial, 264; thyroid extract in, 1104.
Kelynack on alcoholic neuritis, 829; on gall-stones, 182; on gastric carcinoma, 168; on gastric ulcer, 692; on phlegmonous gastritis, 160.
Kempe on thoracopagus, 467.
Kempner on tuberculosis, 33.
Kendal on chronic disease of the tonsils, 1015.
Kennan on pneumonia, 111.
Kennedy on puerperal sepsis, 542.
Kennel on hysteric aphonia, 1027.
Keratitis, 938; aspergillar, 115; filamentous, 939; interstitial, 939; from lightning-stroke, 939; oyster-shucker's, 939; parenchymatous, 939.
Keratoplasty, 941.
Keratosis, follicularis, 1078; universalis multiformis, 1080.
Kerchbaumer on pseudoplasm of the orbit, 911.
Kerr (W. S.) on iliofemoral aneurysm, 340.
Kessler on uterine carcinoma, 631.
Kester on jaundice, 176.
Keyes on pseudochancre, 1099.
Kidd on elephantiasis of the vulva, 558; on intestinal obstruction, 169, 302; on rupture of tendons, 355.
Kidney, action of ether upon, 245; action of poisons on, 700; in atrophic infants, 700; benign tumors of, 412; carcinoma of, 185, 414; catheterization of, 582; in diphtheria, 755; diseases of, 185, 410, 581; displaced, 302; fetal, in puerperal eclampsia, 516; form of, 1156; hygiene of, 1188; movable, 414, 415; position of, 1156; sacculated, 414; sarcoma of, in children, 799; traumatism of, 413; tuberculosis of, 194, 415; in children, 798; tumors of, 195; -tumors derived from suprarenal "rests," 701.
Kiesel on eucain, 1117.
Kiesow on temperature sensation, 1182.
Kiesselbach's place, 1005.
Kilburn on astigmatism, 896.
Kiliani on lumbar puncture, 857.
Killian on the embryonic nose, 996.
King on phimosis, 797; on puerperal tetanus, 541; on the Röntgen rays, 425.
Kinnicutt on exophthalmic goiter, 141, 144.
Kipp on vitreous hemorrhage, 929.
Kirchner on mastoid sarcoma, 981.
Kirikow on hepatic cirrhosis, 178.
Kirkendall on eye-strain, 894.
Kirstein's direct laryngoscopy, 1020.
Kisch on cardiac neuroses, 139; on the menopause, 593; on oxaluria, 187; on puberty, 586.
Kitasato on the plague, 59.
Klautsch on hematoma of the vulva, 544.
Klebs on tuberculosis in children, 776; antiphthisin, 42; -Löffler bacillus, 755.
Klein on antitoxin of diphtheria, 759; on bacilli of the intestines, 714; on diphtheria, 758.
Klein on contracted pelvis, 511; on labor in kyphotic pelves, 513; on tubal pregnancy, 493.
Kleinwächter on sterility, 451; on stricture of the female urethra, 576; on uterine fibroids, 617; on vaginal fibroma, 562.
Klemperer on diabetes mellitus, 82; on hepatic cirrhosis, 178; on uric-acid deposits, 1144; and Levy on typhoid fever, 28.
Klug on nephritis, 194.
Knaggs on gunshot injuries, 443.
Knapp on angioma of the orbit, 911; on entropion, 907; on mastoid operations, 979; on reflex neuroses, 819; on tuberculosis, 39.
Kneass on tetanus, 840.
Knee, amputation at, 230; bony ankylosis of, 883; death after forcible straightening, 883; diseases of, 882; excision of, 375; subluxation of, 375; synovitis of, 882.
Knee-jerk in psychiatry, 865.
Knight on jaundice, 176; on laryngeal icterus, 1029.
Knöpfelmacher on retention of urine, 796.
Kobert on solanum paniculatum, 1140.
Koch on diving, 962; guinea-pig treatment, 57; on sterilization of catgut, 207.
Kocher on amputations, 229; on carcinoma of the rectum, 325; on exophthalmic goiter, 352, 1019; on sterilization of catgut, 207; on thyroid operations, 351, 1169; and Tavel on surgical infectious diseases, 742.
Koehler on tonsillar abscess, 1014.
Kölliker on the optic tracts, 930, 1155.
Kœnig on diabetes mellitus, 84; on the eye in diabetes, 945; on missed abortion, 481; on typhoid fever in children, 771.
Kœnig's theory, 884.
Koeppe on the blood after venesection, 672; on blood-corpuscles, 1163; on gastric juice, 1176; on venesection, 95.
Köppen on pachymeningitis cervicales hypertrophica, 854.
Körner on mastoid abscess in diabetes, 980; on otitic brain-complications, 987.
Körte on suture of the gall-ducts, 319.
Köster on pseudoleukemia, 103.
Kojewnikoff on asthenic bulbar paralysis, 849.
Kolisch on gout, 79, 81; on uric acid, 1173.
Kolisch's theory, 81.
Kolischer on cystitis, 577; on edema of the bladder, 577.
Kolle on cholera-immunization in India, 731; on gonorrhea and endocarditis, 681; on immunization against cholera, 730.
Kollman on syphilis, 1094.
Kollock on abdominal pregnancy, 500.
Kolpohysteropexy, anterior, 609.

Laurent on nasal disease, 950.
Lautenbach on corneal curvature, 895.
Lauw on symphysiotomy, 535.
Lavage of the stomach, 163.
Lavagna on arecetin hydrobromate, 943, 1108; on formol, 943.
Laveran on malarial fever, 54.
Law, Colles's, 215; of infanticide, 1183; Teevan's, 447.
Lawrenson on tetanus, 843.
Lawrie on hydrocele, 408; on malarial fever, 52.
Layer, Langhans', 464.
Layet on vaccinia, 48.
Lazard on meningitis, 793.
Lazarus-Barlow on osmosis, 1164; on typhoid fever, 25.
Lead, convulsions from, 849; -gout, 80; -poisoning, 932; from public water supplies, 1185.
Leahy on postpartum hemorrhage, 544.
Leakage after gastrostomy, 270.
Leathes on osmosis, 1165.
Leber on conjunctivitis petrificans, 916; on foreign bodies in the eye, 953; theory of papillitis, 934.
Le Blonde and Lévy on vaginitis, 556.
Le Cato on endemic fever, 18.
Le Damany on chancroid, 1098.
Ledbetter on sympathetic ophthalmia, 921.
Le Dentu on appendicitis, 171; on twin tubal pregnancy, 495; on vicious ankylosis, 881.
Leder on irritable bladder, 577.
Lederhose on hemiplegia, 833.
Lederman on nasal sarcoma, 1005.
Ledoux on coagulation of the blood, 1162.
Lee on pernicious vomiting of pregnancy, 468.
Leeds on the Dresden mixture, 750; on milk, 1186.
Lees on dystocia, 521; on rheumatism, 72.
Lefevre on pleural exudates, 117.
Le Fort on traumatic dermoid cysts, 253.
Lefour on asepsis in labor, 503; on curettage, 603.
Leg, amputation of, 229; -ulcers, zinc-jelly bandage for, 416; varices of, 339; white, 541.
Legars and Levi on placental polypus, 488.
Le Gendre on heredity and alcoholism, 865.
Legnun on cystitis, 402.
Legrain on lupus erythematosus, 1072; on typhus fever, 57.
Legueu on atrophy of the prostate, 1170; on postoperative intestinal obstruction, 303; on renal neuralgia, 415.
Leichsenring on kosotoxin, 1126.
Leimbach on locomotor ataxia, 851.
Leistikow on burns, 416.
Leith on cardiac disease, 135; on rupture of the pancreas, 311; on tuberculosis, 34.
Lejars on sepsis, 218.
Lemaistre on chalicosis, 115.
Lemariey on hypertrophy of the tonsils, 1015; on Ménière's disease, 969.
Lemoine on nondiphtheric angina, 691: on scarlatina, 768; on contagion of scarlatina, 766.
Lenhartz on lumbar puncture, 858.
Lenier on sepsis, 218.
Lens, 892; and its capsule, diseases of, 935; congenital dislocation of, 938.
Lenses, form of, 899.
Leo on the Röntgen rays, 199.
Léon on hysteropexy, 614.
Leontiasis ossium, 388.
Leopold on congenital erosion of the cervix uteri, 571; on contracted pelvis, 512; on emphysema after abdominal section, 656; on fibromyoma in pregnancy, 480; on vaginofixation, 615; and Orb on external examination in labor, 505.
Lépine on diabetes mellitus, 83; and Viaud on hiccough, 822.
Lepra, 59, 1066; -bacilli in syringomyelia, 686; of the larynx, 1022.
Leprosy, 59, 1066; anesthetic, 860; in Iceland, 1070; in Kashmir, 1069; in Nova Scotia, 1068.
Leprous iritis, 919.
Leptomeningitis, purulent, after acute otitis media, 964.
Leptothrix buccalis, 1016.
Leredde and Perrin on Duhring's disease, 1040.
Lermoyez on coryza, 1001.
Lesions produced by lightning-stroke, 741.
Leslie (G.) on nasal pain, 1003.
Lesser on fever, 68.
Leszynsky on cretinism, 826; on neuritis after pneumonia, 828.
Leube on intestinal perforation, 301.
Leube's method, 1119.
Leukemia, 101, 669; and the acute infectious diseases, 677; bone-marrow in, 102; lymphatic, 101; priapism in, 101; protozoa in, 101; splenic, 101; symptoms, 101.
Leukocytes, 92; in pneumonia, 93, 112; in tuberculosis, 93; in typhoid fever, 93; in the urine in nephritis, 193.
Leukocythemia, bone-extract in, 1107.
Leukocytosis of diphtheria under serum-therapy, 672; after injection of albumoses, 92; in pneumonia, 92; and uric-acid elimination, 92, 700.
Leutert on acute otitis media, 966, 977.
Leukomain-headache, 78; poisoning by, 78.
Levi on diseases of the liver, 182; on hepatic disease, 174; and Laurens on edema of the larynx, 1022.
Levrey and Ghika on retropharyngeal abscess, 1017.
Levy on pneumothorax, 118, 119; -Dorn on tetany, 839.
Lewers on double uterus, 594; on vaginal hysterectomy, 635.
Lewi (E.) on infantile myxedema, 781; on sarcoma of the kidney, 800.
Lewin on keratosis universalis multiformis, 1080; on phenylhydroxylamin-poisoning, 1132; on supernumerary digits, 1159.
Lewis (B.) on cocain-anesthesia,

239; on inflammation of the lingual tonsils, 1013; on melæna neonatorum, 753.
Leyden on cardiac tuberculosis, 678; on tuberculosis, 43; on tuberculosis of the kidneys, 195; on tuberculous endocarditis, 126.
Leyden's sign, 306.
Lichen ruber acuminatus, 1080.
Lichtenberg on excision of the ossicles, 976.
Lichtenstein and Bryant on intussusception, 310.
Lichtheim on lumbar puncture, 856, 989.
Lichtwitz on chronic disease of the tonsils, 1015; on sinusitis, 1009.
Lick on tuberculosis of the lacrimal gland, 909.
Lidbretter on cataract, 937.
Liddell on pityriasis rubra pilaris, 1079.
Liebmann on the stomach test, 1185.
Liebrecht on argonin, 1109.
Lieven on syphilis of the pharynx, 1016.
Ligament, cervical, 359; infundibulopelvic, 1157.
Ligation of carotids for nasal sarcoma, 1005; of the common iliac artery, 341; of the iliac arteries for prostatic hypertrophy, 407; of the umbilical cord, 509; of the ureter, 623; of the vasa deferentia for prostatic enlargement, 407.
Ligature in abdominal section, 651; distal, for aneurysm, 340; of the innominate artery, 341; -material, 209.
Lightning, effect of, on the eye, 934; -figures, 741; -stroke, keratitis after, 939; -stroke, lesions produced by, 741.
Light-sense, 925.
Lignosulphit, 211.
Lilienfeld on coagulation of the blood, 1162.
Lilienthal on osteoplastic operation, 368.
Lilienthal's bullet-probe, 445.
Limbs, crushes of, 418.
Limbus, carcinoma of, 917.
Limerick food-poisoning cases, 1185.
Lime salts, absorption and elimination of, 778.
Linderer on Frank's method, 270.
Lindner on dislocation of the lens, 938.
Linea quadrati of the femur, 1148.
Lingual tonsil, acute inflammation, 1013; tonsils and cough, 107.
Linossier on the urine, 185; and Roque on glycosuria, 1120.
Linsey on the leukocytes, 92.
Lip, carcinoma of, 258; diseases of, 350.
Lipinsky on vaginal atresia, 566.
Lipoma of the larynx, 1022; protozoan in, 708.
Lippincott on glaucoma, 922.
Lister on Gritti's amputation, 230.
Liszt on pneumonia, 114.
Lithemia, 77; sodium salicylate in, 78, 1137.
Lithiasis in children, 798; and circumcision, 798.
Lithia-water in gonorrheal ureteritis, 556.
Lithium carbonate in diabetes mellitus, 86; salts in the uric-acid diathesis, 186.
Litholopaxy, 406.
Lithotomy, intraperitoneal suprapubic, 404.
Lithotrity, 405; in children, 406.
Litten on the diaphragm-phenomenon, 107.
Little on retinal detachment, 928.
Littlewood on cyst of the pancreas, 312.
Liver, abscess of, 179, 315; abscess of, in typhoid fever, 23, 216; abscess of, after dysentery, 59; acute yellow atrophy of, 179; in children, 783; amebic abscess of, 315; carcinoma of, with cirrhosis, 695, cirrhosis of, 177; in Hodgkin's disease, 103; diseases, 175, 315; -diseases in children, 782; -disease, somnolence in, 182; echinococcus cysts of, 180; glycogenic function of, 1170; hydatid cysts of, 180; icing-, 695; malformations of, 181; in pernicious anemia, 98; rupture of, 315; in typhoid fever, 719.
Livierato on expired air, 1185; on the toxicity of the breath, 742.
Ljubomudroff on typhoid fever, 719.
Lloyd (J. H.) on spinal cord in pernicious anemia, 850.
Lobar pneumonia in diabetes mellitus, 84; empyema after, 119; after etherization, 250.
Lobular pneumonia, etiology, 698; pathology, 698.
Local action of salol, 210; anesthesia, 233–240; anesthesia in dermatology, 1088; changes produced by intramuscular injections of insoluble mercurials, 1096; eosinophilia in carcinoma, 671; infection of the ear, 960; peritonitis, 173; tuberculosis, 221.
Lockwood on hernia in children, 280; on hernia of the ovary, 664; on hydrocele, 408; on otitic sinus-phlebitis, 990; on strangulated hernia, 283.
Locoarret on acute otitis media, 967; on cholesteatoma of the ear, 978.
Locomotor ataxia, 851; anesthesia, 851; cerium oxalate in, 854; choked disk in, 854; cystic incontinence in, 851; eye in, 947; gastric crises in, 854; optic neuritis in, 854.
Lodato on hydrophthalmos, 893.
Löffler and Abel on the typhoid-bacillus, 729.
Löhlein on ovarian cysts, 662.
Löhr on sarcoma of the bladder, 800.
Löwenthal on tumors of traumatic origin, 263.
Lohnstein on sugar in the urine, 1175.
Lomry on acne, 1081.
Long on placenta prævia, 483; on transvaginal surgery, 644.
Longe on the eye in hereditary ataxia, 947.
Longfellow on impregnation, 453.
Longyear on buried sutures, 651; on kraurosis vulvæ, 553.
Loomis on cardiac syphilis, 146.
Loos on diphtheria-toxin, 732.
Loose bodies in joints, 884.
Lorenz on ankylosis of the hip, 880.
Loreta's operation, 268.
Loretin, 210.
Lotion, Boeck's, 1086.
Louisiana, continued fevers of, 18.
Love on scurvy, 779.
Lowenstein on catgut, 208.
Lowoff on symphysiotomy, 535.
Lowson on the plague, 59.
Lubarsch on amyloid degeneration in tumors, 706; on carcinoma of the stomach, 684; on exophthalmic goiter, 703; on renal tumors, 701.
Lubet-Barbon on eburnation, 979; on mastoid abscess, 978.
Lubinski on laryngeal paralysis, 1028.
Luc on nasal polypi, 1004; on otitic cerebellar abscess, 992.
Lucas on local anesthesia, 1088; on otitic sinus-phlebitis, 990.
Lucciola on the ophthalmometer, 955.
Luciani on blepharitis, 944.
Lucilia macellaria in the ear, 959.
Lucy on hernia in children, 281
Ludwig on Cesarean section, 537; and Savor on puerpera, eclampsia, 516.
Leuthje on gout, 80.
Luffier on sodium fluorid, 211.
Lugo-Vina (N.) on Brazilian lantana, 1110.
Lui on epilepsy, 813.
Lumbar colostomy, 310; puncture, 855.
Lumboabdominal palpation, 640.
Lund on local anesthesia, 237.
Lung, abscess of, 115, 331; anatomy of, 1156; aspergillosis, 698; bile-forming cancer-nodules in, 704; carcinoma of, 120; contusion of, 332; diseases of, 107; edema of, 114; expansion, 336; fat-embolism of, 883; gangrene of, 330; hemorrhage from, 329; injuries of, 329; lymphatics of, 1149; primary actinomycosis

of, 698; protozoa in, 116; surgery of, 328.
Lupus, 220; erythematosus, 1070; erythematosus disseminatus in pregnancy, 1072; erythematosus, sheep's serum in, 1072; excision of, 220; of the larynx, 1025; lymphaticus, 349; of the palate, 1025; vulgaris, 1072.
Lusk on asepsis in labor, 503; on phloridzin-diabetes, 1171; on skin-grafting, 419.
Lusteck on cutin, 209.
Lutaud on amenorrhea, 587.
Luxation, 371; erecta of the shoulder-joint, 374.
Lycetal, 1126.
Lydson on eye-strain, 894.
Lydston on chancroid and chancre, 1097.
Lymphadenoma, 103, 677.
Lymphangioma cutis circumscriptum, 349; cystic, in childhood, 348; of the helix, 958; of the orbit, 911.
Lymphatic leukemia, 101; system, diseases of, 348; vessels, regeneration of, 1149.
Lymphatics, 1148; of the anus, 1148; of the bladder, 1149; of the lung, 1149; of the rectum, 1148; of the umbilicus, 1149.
Lymphemia, 669.
Lymph-formation, osmosis and, 1163.
Lymphoglandulæ vesicales anteriores et laterales, 1149.
Lymphoid nodules of the liver in typhoid fever, 719.
Lymphosarcoma of the spleen, 668.
Lymphotrophy, 707.
Lysol in labor, 503.

Maas on genital tuberculosis in children, 659.
Maberley on carbuncles, 219.
Macalister on nocturnal enuresis, 796.
McArtney on appendicitis, 171; on tetanus, 842.
McBride on chronic otorrhea, 979; on foreign bodies in the ear, 959; on lupus of the larynx, 1025; on nasal polypi, 1004.
McBurney on amputation of the forearm, 229; on appendicitis, 289; on dislocation of the humerus, 374; on malignant tumors, 254.
M'Callum on congenital atresia of the hepatic duct, 782.
McCann on culture-media, 736; on ovarian cysts, 663.
M'Causland on the *x*-rays, 426.
McColl on cardiac disease, 137; on tubal pregnancy, 493.
MacCormac on amputations, 224; on military surgery, 436.
McCormick on guaiacol, 1122; treatment, 383.
McCosh on mixed anesthesia, 247; on subphrenic abscess, 268.
McDonald on cardiac anomalies, 786; on sugar, 1194.
McDougal on leprosy, 1066.
McDowell on tuberculosis, 39.
Macé on psychoses of lactation, 546; on puerperal insanity, 472; on subcutaneous emphysema during labor, 528; on valvular cardiac disease in pregnancy, 470.
Macewen on hernia in children, 281; on otitic cerebral complications, 982; on purulent otitis media, 974.
Macewen's method, 148.
Macfarlane on puerperal sepsis, 542.
McGuire on relapsing appendicitis, 290.
Machell on scurvy, 779.
MacIntyre on the *x*-rays and the larynx, 1021.
McKelway (G. I.) on repeated extrauterine pregnancy, 497.
Mackenrodt on hysterectomy, 637; on hysteropexy, 613, 614; on the position of the uterus, 604; on vaginofixation, 610.
Mackenzie on aseptic wounds, 202; on cyst of the larynx, 1025; on purpura rheumatica, 1057; on rheumatism, 172.
Mackid on epilepsy, 814.
Mackness on puerperal eclampsia, 514.
McMullen (J.) on hemorrhage, 344.
Macnamara on arthritis, 370.
MacNaughton-Jones on chronic catarrhal otitis media, 968; on Ménière's disease, 969; on nerve-deafness, 973; on turbinotomy, 972.
McNeill on intestinal enemata in hemorrhage, 344.
Macphail on twins, 530.
McPhedran on malformation of the liver, 181.
Macready on hernia, 278; on hernia in children, 281.
Macrodactyl, 349.
Macroesthesia, 811.
McTaggert on tuberculosis, 39.
McWeeney on renal tumors, 196, 701
Madden (J.) on dysmenorrhea, 590.
Madelung's method, 339.
Madlener on anterior kolpotomy, 609; on metritis, 596.
Madura foot-disease, 1055.
Maffucci and Di Vestea on tuberculosis, 731.
Maggots in the ear, 959.
Magill on choledochotomy, 316.
Magitot on phosphorism, 1133.
Magnesium sulphate in dysentery, 58; in summer diarrhea, 784.
Magniaux on membranous bronchitis, 697.
Magnus-Levy on gout, 81; on thyroid treatment, 90.
Mahaim on the eyeball, 1152.
Mahe on the plague, 60.
Mainzer on the menopause, 658; on ovariectomy in pregnancy, 480.
Maiweg on carcinoma of the lip, 258.
Major amputations, 223.
Makins and Abbott on osteomyelitis of the spine, 395.
Malaria, eczema from, 1033; in pregnancy, 485; Roman method of treatment, 485.
Malarial cachexia, spleen-extract in, 1107; fever, 52; algid form of, 54; anarcotin in, 1102; asaprol in, 801; blood in, 53; boxwood in, 1110; diagnosis, 56; etiology, 52: guaiacol in, 1121; hyperpyrexial, 54; infusoria in, 1136; mosquito in, 54; parasites in, 52; pernicious, 53; phenol in, 57; splenic hypertrophy in, 54, statistics, 56; symptoms, 54; treatment, 57; trional in, 802; organism, 53.
Malcolm on abdominal section, 649.
Malformation, congenital, of the auricle, 958; of the eye, 892; of the liver, 181; of the penis, 1156; of the urethra, 1156.
Malgot on albinism, 918; on trachoma, 915.
Malherbe on tubal pregnancy, 494.
Malignant adenoma of the uterus, 630; deciduoma, 488; disease, diagnosis, 255; erysipelas-toxins in, 735; etiology, 255; treatment, 255; of the uterus, 623; endocarditis, 123; growths, serumtherapy in, 254; tendency after iridectomy, 923; tumors, erysipelas-toxins in, 253; prognosis, 262.
Mallett on drainage, 652.
Malleus, extraction of, 976; fracture of, 962.
Malpractice, 1183.
Malta fever, 18.
Malt-extracts, 1126.
Mamma, pathology of, 545.
Mammæ, supernumerary, 546.
Mammary abscess, 213; septicemia from, 215; gland, cystic degeneration of, 265; tuberculosis of, 717.
Man, trichomonas in, 743.
Manasse on pyloric obstruction, 164.
Mandelstamm on acute otitis media, 965; on syphilis of the orbit, 912.
Manganese in chlorosis, 98; in exophthalmic goiter, 143.
Mangold on infection of ovarian cysts, 662.
Mangoldt on skin-grafting, 419.
Mangue on Raynaud's disease, 795, 832.

Manicatide on tuberculosis in children, 775.
Manipulation, Credé's, 507; in pregnancy, 458.
Mann (M. D.) on arsenic, 1190; on fibroid tumors in labor, 521; on malignant adenoma of the uterus, 630; on mercuroiodohemol, 1127; on neurasthenia in women, 552; on perforation of the uterus after abortion, 486; on secondary abdominal pregnancy, 498.
Mannaberg on leukemia, 101.
Manner on dysentery, 59.
Manson on malarial fever, 53, 54.
Mantle on rheumatism, 71.
Manton on puerperal eclampsia, 518.
Manz on ocular tuberculosis, 919; on the optic nerve, 930.
Maragliano on tuberculosis, 33; on tuberculosis in pregnancy, 473.
Maragliano's serum, 41; treatment of tuberculosis, 41.
Marcarenhas (A.) on symphysiotomy, 535.
Marcet on asthma, 116.
Marchand on deciduoma malignum, 463.
Marchetti on retinal detachment, 928.
Marchoux on antianthrax serum, 734.
Marcy on buried sutures, 203, 209; on spina bifida, 382; on stone in the gall-bladder, 320; on tetanus neonatorum, 753.
Marduel on pernicious vomiting of pregnancy, 468.
Marfan on pertussis, 773; and Apert on infantile tuberculosis, 775; and Hallé on varicella, 772.
Marfori on ferratin, 1120.
Marie (P.) on acromegaly, 846; on cystic albuminuria, 188; on pigmentary diabetes, 84; on spinal sclerosis, 794; on thoracic deformities, 108.
Marie's theory, 108.
Marina on the iris, 918; on ophthalmoplegia, 905.
Marinesco on acromegaly, 844; on multiple neuritis, 829; on polyneuritis, 687; on tetanus-toxin, 689.
Marks on spontaneous rupture of the uterus, 478.
Markzellen, 92.
Marmorek on erysipelas, 50.
Marmorek's antistreptococcic serum, 17, 50, 219, 542, 734; in cellulitis, 219; in erysipelas, 219; in membranous bronchitis, 109; in scarlatina, 767.
Marple on embolus of the optic nerve, 934; on the eye in hysteria, 945.
Marpurgo on chronic otorrhea, 975; on otitic cerebral complications, 986.
Married couples, diabetes mellitus in, 82.
Marrow-extract, 1107.
Marschner on tetany, 838.
Marsh on bony ankylosis of the knee, 883; on displacements of muscles, 888; on joint-ankylosis, 377; on the *x*-rays, 425.
Marshall on detachment of the choroid, 924; on empyema, 335; on foreign bodies in the eye, 952; on retinal detachment, 928.
Marson on tetanus, 840.
Martin (A.) on anterior kolpotomy, 647; on the curet, 602; on dysmenorrhea, 590; on ligation of the ureter, 623; on malignant adenoma of the uterus, 630; panhysterectomy, 632; on transvaginal surgery, 644; on vaginal fibroma, 563.
Martin (C. F.) on carcinoma, 628; on osteoma of the orbit, 912; and Kiersted on syphilis, 1096.
Martin (E.) on the Laborde method, 250.
Martin (S.) on the diphtheria-bacillus, 762.
Martins on exophthalmic goiter, 140.
Marx (S.) on extrauterine pregnancy, 494; on rupture of the uterus, 625; on vulvovaginitis, 797.
Masini on senile deafness, 969.
Masius on toxic amblyopia, 931.
Masked tuberculosis, 33.
Masoin and Du Bois-Reymond (R.) on the intercostal muscles, 1178.
Mason on trephining for epilepsy, 816.
Massage in acne of the face, 1082; corneal, 941; gastric, 163; of the middle ear, 972; in sprains, 372.
Massei on stenosis of the larynx, 1022.
Massin on puerperal eclampsia, 517.
Mastoid abscess, 978; auscultation of, 981; carcinoma of, 981; caries of, 979; cells, spontaneous rupture of, 980; in diabetes, 980; disease, 391, 978; skin-grafting in, 391; empyema, 965; epithelioma of, 981; operation, 979; sarcoma, 981.
Mastoiditis, 979; after acute otitis, 964; Bezold's, 980; hysteric, 981; periphlebitis of the jugular after, 964; primary, 978; suppurative, treatment, 965; tuberculous, 981.
Matas on continued fever, 18.
Materia medica, 1100.
Maternal blood at birth, 505; death during labor, 528; dystocia, 511.
Mathaei on conservative pelvic surgery, 654.
Matheson on inversion of the uterus, 526.
Mathewson on exostosis of the ear, 960.
Matthes on the urine, 189.
Matthiew on hiccough, 822; and Trêheux on acidity of the gastric juice, 154; on the urine, 185.
Mattison on opium-poisoning in children, 803.
Maturity, signs of, at birth, 546.
Matveiff on pregnancy in a double uterus, 477.
Maud on exophthalmic goiter, 864.
Maugue on Raynaud's disease, 795, 832.
Mauriac on chancres, 1092.
Mauthner on keratitis, 939.
Max on exostoses of the ear, 960; on lymphangioma of the helix, 958.
Maxey on myxedema. 825.
May on trachoma, 915.
Maybaum on exophthalmic goiter, 142.
Maydl on subphrenic abscess, 267, 306.
Mayer on the blood, 90; on calcium permanganate, 211; on hypertrophy of the prostate, 407; on unruptured hymen, 520.
Mayet on dysmenorrhea, 592.
Maynard on opium-poisoning, 1134.
Mayne on postpartem hemorrhage, 544.
Mayo on Cesarean section, 536; on intubation, 1023.
Mays (T. J.) on tuberculosis, 37.
Mazet on lacrimal diseases, 908.
Mazza on syphilis, 1094.
Measles, 764; diarrhea in, 764; eye in, 951; otitis in, 765, 964; peritoneal exanthem in, 765; trional in, 802.
Meat and milk from tuberculous animals, 31.
Mechanism of labor, 508.
Meckel's ganglion, resection of, for neuralgia, 384.
Median cervical fistula, 353.
Medical jurisprudence, 1183.
Medication of the bronchus, 1030.
Medicine, general, 17.
Medin on infantile paralysis, 794.
Mediterranean fever, 18, 64.
Medulla oblongata and exophthalmic goiter, 140; pyramids of, 1152.
Medullated fibers of the brain, 1154; nerves of the skin,
Megastoma entericum, 179.
Mégnin on entomology, 1183.
Mehrer on absence of the uterus, 595.
Mehrtens on puerperal sepsis, 543.
Meirer on caries of the ear, 977; on suppuration of the middle ear, 989; and Webber on carcara sagrada, 1112.

Meinert on emphysema after abdominal section, 656; on the stomach, 155, 157.
Meisels on uricedin, 1145.
Melancholia from intranasal disease, 1003; thyroid extract in, 1104.
Melanosarcoma of the cornea, 941.
Melena neonatorum, 753.
Melkinow-Raswedenkow on infectious diseases, 703.
Mellor on the eye, 954.
Meltzer on gastric digestion, 1175.
Membrana tympani, traumatic perforation of, 961.
Membrane of a hen's egg in grafting, 419; peridental, sarcoma of, 690; premature rupture of, 461.
Membranous angina, nondiphtheric, 789; bronchitis, 109, 697; dysmenorrhea, 590; rhinitis, etiology, 1000.
Mempanthis trifoliata in amenorrhea, 588.
Memphis stone, 239.
Ménard on juxtaarticular tuberculous ostitis, 881.
Mendel on Bezold's mastoiditis, 980; on intestinal juice, 1176; on lymph-formation, 1165; on subcutaneous injections of fat, 1119; on ulcerative tonsillitis, 1014.
Mendelssohn on nocturnal incontinence, 831; on tuberculosis of the kidneys, 194.
Menge on vaginal secretion in the nonpregnant, 555.
Ménière's phenomena, 969.
Meningism, 806.
Meningitis, 836; after acute otitis media, 964; cerebrospinal, 836; in children, 792; otitic, 994; tuberculous, 776, 793; tuberculous, vascular changes in, 687.
Meningocele, 386.
Menopause, 592; atresia of the uterus at, 593; and exophthalmic goiter, 592; tachycardia at, 593; thyroid extract in, 658; treatment, 658.
Menorrhagia, 588.
Menstruation, 583; age of, 586; phenomena of, 586; precocious, 586; vicarious, 587.
Mental changes in exophthalmic goiter, 864; diseases, 804, 864; and pelvic disease, 552; in pregnancy, 471.
Menthol in coryza, 1001; in phthisis, 1030.
Mercurial eruptions, 1052; multiple neuritis, 827; ointment, erythema scarlatinoides from, 1052.
Mercuric acid nitrate in lupus vulgaris, 1072; biniodid in dysentery, 58; chlorid in anemia, 95; in gonorrheal vulvitis, 557; in leprosy, 1069; in pernicious anemia, 100; in puerperal sepsis, 542; cyanid in eye-diseases, 943.
Mercuroiodohemol, 1127.
Mercury in cardiac disease, 138; in cerebrospinal meningitis, 836; hypodermic injections of, in syphilis, 1096; oxycyanid of, 210; red oxid of, in anal pruritus, 327.
Merkel on borax in constipation, 1110; on intestinal atony, 168; on ovariectomy in pregnancy, 480.
Mermann on gall-stone operation, 322.
Merrick on hysteric aphonia, 1027.
Merriman on scurvy, 779.
Méry on scarlatina, 768.
Merycism, 161.
Mescal buttons, 1103, 1104.
Mesenteric cysts, 174.
Meslay and Jolly on measles, 764.
Mester on aneurysm of the hepatic artery, 181.
Metabolism, 1168; potassium and sodium chlorid in, 1112.
Metabolites, nitrogenous, 1173.
Metastasis in carcinoma, 264.
Metastatic choroiditis, 924.
Metatarsalgia, 425.
Methylene-blue in chyluria, 198; in urethritis, 379.
Methyl-violet in corneal ulcer, 940.
Metritis, 595; and gonorrhea, 596; in pregnancy, 475; in uremia, 596.
Metrorrhagia, 588; calcium chlorid in, 589; cotarnin hydrochlorid in, 590; ferripyrin in, 590; salipyrin in, 589; steam in, 588; stypticin in, 590.
Metschnikoff on the cholera-vibrio, 724; on infectious diseases, 703.
Mettler on gastric ulcer, 166.
Meyer (W.) on adenoids in children, 1011; on appendicitis, 289; on Bier's treatment, 885; on chorea, 793; on retropharyngeal abscess, 1017; on scurvy, 779; on tonsillitis, 1014; on tuberculosis of the kidney, 415.
Michael on purulent otitis media, 974.
Michaelis on hysteropexy, 614; on solanum paniculatum, 1140.
Michailowa on abortion, 488.
Michel on the optic tracts, 930.
Michie on pelvic suppuration in pregnancy, 476.
Michigan, goiter in, 149.
Micrococcus Brisow, 758; lanceolatus in the ovary, 666; tetragenus versatilis, 58; in bronchitis, 109; in chancroid, 715; in gastric ulcer, 165; in inspired air, 713; in the intestines, 172; in milk, 1187; in rheumatism, 72; and suppuration, 713.
Middle ear, carcinoma of, 976; disease and the tonsils, 1014; diseases of, 962; hairy granulation-tumor of, 960; massage of, 972; senile changes in, 969; suppuration of, 974; surgery of, 981; tuberculosis of, 976; meningeal artery, 387; turbinated, necrosis of, 1009.
Midwives, 450.
Migneco on tubercle-bacilli, 716.
Mikhalkine on nitroglycerin, 1128.
Mikulicz on exophthalmic goiter, 352; on gastric ulcer, 267; on goiter, 1018; on the hip, 879.
Miländer on dystocia after ventrofixation, 522.
Miles on fluid discharges from the ear, 390; on skin-grafting, 419.
Miliary tuberculosis, leukocytes in, 93.
Military surgery, 429.
Milk, albumose-, 779; condensed, analysis of, 746; cow's, analysis of, 746; fat-, 747; human, 510; microorganisms in, 1187; modified, 1186; staphylococcus albus in, 546; sterile, 1186; sterilized, scorbutus from, 548; from tuberculous animals, 31; uncooked, and cholera-bacilli, 1186; vegetable, 749.
Miller on amputation, 230; on carcinoma of the pancreas, 696; on pulmonary lymphatics, 1149; on scurvy, 779; and Ring on lead-poisoning, 932.
Milligan on foreign bodies in the ear, 959; on purulent otitis media, 974; on teacher's nodes, 1029; on tuberculosis of the ear, 976; and Barr on nerve-deafness, 973.
Milliken (S.) on dermoid cyst of the orbit, 912; on retinal detachment, 928; on tendon-transplantation, 886.
Milton (H.) on lithotrity, 405.
Mind-blindness, 949.
Mingaud on entomology, 1183.
Mink on bacteria, 712.
Mintz on carcinoma of the esophagus, 152.
Missed abortion, 481; labor, 481.
Mitchell (L. J.) on air-embolism after abortion, 486.
Mitchell (S. W.) on hysteric contractures, 807.
Mitchell (T. E.) on extrauterine pregnancy, 496.
Mitchell (W.) on bromic poisoning, 1110.
Mitia on cholera, 57.
Mitra on intestinal parasites in children, 786; on leprosy, 1069.
Mitral regurgitation, 131; stenosis, 130.
Mittelschmerz, 591.
Mittendorf on ametropia, 893;

on astigmatism, 896; on the quarter-diopter cylinder, 897.
Mitvalsky on choroidal tumors, 924; on orbital thrombophlebitis, 911.
Mixed anesthesia, 246.
Models for measuring deformity in hip-disease, 881.
Modified milk, 1186.
Möbius on puerperal polyneuritis, 545.
Möbius's theory, 140.
Mörner on the urine, 1175.
Moffatt on extrauterine pregnancy, 495.
Moikowski on red blood-corpuscles, 1163.
Moizard and Bouchard on antitoxin, 763.
Mokes on carcinoma of the larynx, 1025.
Mole, hydatidiform, 462.
Molinie on laryngitis sicca, 1021.
Moll on persistent hyaloid artery, 892; on postdiphtheric cycloplegia, 918.
Mollusca fibrosa, 1084; bodies, 1061; contagiosum, cells in, 1061; in the eyelid, 907; parasites of, 1060.
Monakow (V.) on the brain, 1179.
Moncorvo on asaprol in children, 801; on spinal sclerosis, 794; on trional in children, 802.
Monell on Röntgen rays, 420; on sciatica, 819.
Monestié on cutaneous actinomycosis, 1054.
Money, bacteria on, 712.
Mongour on intestinal concretions, 171.
Monnier on hepatic cirrhosis, 178.
Monod on diphtheria, 759; and Michaux on sepsis, 218.
Monster, double, 751.
Monstrosities, fetal, 466.
Montgomery on belladonna-poisoning, 1109.
Montgomery (E. E.) on transvaginal surgery, 644.
Montouri on infectious diseases, 703.
Moore on extrauterine pregnancy, 494; on tuberculous osteomyelitis, 878.
Moosbrugger on trichocephaliasis, 196.
Moraczewska (S.) on anemia, 672; on tuberculosis, 34.
Morain on anal pruritus, 327.
Morax and Bach on catarrhal conjunctivitis, 914.
Morcellation, 620.
Morgan on foreign body in the bronchus, 332; on hernia in children, 282; on vaccinia, 48.
Morgan (J. H.) on inversion of the uterus, 526.
Morison on gall-stone operation, 321.
Morits on gastric digestion, 1175; on intragastric pressure, 156.
Morphin in cerebrospinal meningitis, 836; in dysmenorrhea, 592; in edema of the lungs, 114; -injections in extrauterine pregnancy, 501; in labor, 507; in puerperal eclampsia, 518; stearate, 1140; in typhlitis, 171.
Morphinism, congenital, 803.
Morphœa herpetiformis, 1062.
Morpurgo on ear-diseases, 971.
Morra on acute otitis media, 965.
Morrill on diphtheria, 763.
Morris (M.) on appendicitis, 290; on eczema, 1035; on goiter, 149, 1018; on lupus erythematosis, 1071.
Morrison on after-effects of ether, 247; on bradycardia, 139; on cardiac disease, 137; on diabetes mellitus, 87; on refraction, 897.
Morrow (P.) on diabetes, 1050; on syphilis, 1091.
Morse on adenoids, 968; on malarial fever, 53; on scurvy, 779; on typhoid fever, 22; in children, 771.
Mortality of empyema in childhood, 334; in young primiparæ, 455.
Morton on blepharospasm, 906; on corneal massage, 941; on syphilis of the conjunctiva, 917.
Morton (H. M.) on Ritter's disease, 549, 1043.
Morton (T. G.) on backward dislocation of the carpus, 374; on pseudoerysipelas, 900; on sarcoma of the orbit, 917; on the *x*-rays, 425, 426.
Morton's (T. G.) painful affection of the foot, 425.
Morvan's disease and syringomyelia, 859.
Moseley on extrauterine pregnancy, 496; on twin pregnancy, 529.
Moser on malarial fever, 53.
Mosetig on the Röntgen rays, 424.
Mosler on splenectomy, 313; on splenic echinococcus, 314.
Mosquito and malarial fever, 54; and yellow fever, 58.
Moss on biliary colic, 182; on the liver, 1170.
Mosso on cocain-poisoning, 235; on muscular energy, 1172.
Motherhood, precocious, 453.
Motility of bacteria, 711.
Motion in fractures, 356.
Motor aphasia, 1028; nerves of the muscles of the eyeball, 1152.
Mott on multiple neuritis, 829.
Moullin on enlarged prostate, 408; on otitic sinus-phlebitis, 990.
Mountain fever, 18; -sickness, 1177.
Mouquet on arecolin hydrobromate, 1108.
Moure on angioma of the ear, 962; on chronic otorrhea, 976; on ear-diseases, 971; on intratympanic surgery, 972; on topography of the skull, 979.
Mouson on empyema, 335.
Moussous on postserotherapic eruptions, 764.
Mouth, ulceration of, in typhoid fever, 21.
Mouth-breathing and salivary calculus, 1012.
Movable kidney, 414, 415.
Movement, abnormal associated, of the eyes, 901.
Mowat on phlegmasia alba dolens, 541.
Mubille on blepharitis, 906.
Mucosa, nasal, anatomy of, 996.
Mucus, rectal, in tuberculosis, 43.
Müller (E.) on acute osteomyelitis of the spine, 394; on the blood, 671; on diphtheria of the skin, 1047; on endometritis, 599; on sight, 1182; on uterine carcinoma, 629; on wound of the cornea, 941.
Müller's method, 489.
Müller-Quénu's morcellation, 621, 649.
Muggia on presentation of the face, 532.
Muir on medication of the bronchus, 1030.
Mulford on the nose, 1004.
Mulhall on the cigaret-habit, 1021.
Multiform erythemata, 1031.
Multiple aneurysms, 147; gunshot wounds of the intestines, 445; laryngeal papillomata, 1024; neuritis, 829; in children, 795; mercurial, 827; in pregnancy and childbed, 828; osteomyelitis, 370; primary carcinoma, 704; pregnancy, 529; sclerosis, 685.
Mundé (P.) on Alexander's operation, 607.
Munger on argentamin, 1109; on acetanilid, 1101; on formalin, 1120; on rhinitis, 1130; on tannigen, 1143.
Munk (H.) on the brain, 1180; on cow's milk, 746.
Munson on goiter, 149, 1018.
Murder-trials, stomach-test in, 1185.
Murdoch on the ophthalmometer, 956.
Muret on tubal abortion, 497.
Murmur, aortic, in anemia, 94; cardiac, 129; presystolic, 128; pseudodiastolic, 131.
Murphy on fibroma of the vagina, 562; on fibromyoma in pregnancy, 480; on intestinal anastomosis, 300; on relapsing appendicitis, 290.
Murphy's button, 295.
Murray (G. P.) on cardiac disease, 138; on hysteria and tetany, 810; on myxedema, 89; on thyroid treatment, 824.
Murrell on Addison's disease,

105; on cycloplegia, 900; on guaiacum, 1123.
Murri on asthenic bulbar paralysis, 848.
Muscatello on absorption, 1166.
Muscles, abdominal, absence of, 1159; diseases of, 354, 888; displacements of, 888; intercostal, 1178.
Muscular atrophy after diabetes mellitus, 84; progressive, 684; dystrophy, atypical, 823; irritability in pneumonia, 111; work, energy of, 1171.
Musculospiral nerve, complete division of, 383.
Musser (J. H.) on duodenal ulcer, 1170; on pernicious anemia, 98; on typhoid fever, 22.
Mustard as an antiseptic, 211.
Myasthenia gravis pseudo-paralytica, 847.
Mycetoma, 1054; of the foot in America, 1055.
Mycosis of the cervix uteri, 600; of the throat and nose, 1016.
Mycotic dysphagia, 151.
Mycoticopeptic ulcer of the stomach, 692.
Mydriasis cured by hypnotism, 813.
Mydriatics, 943.
Myelitis, compression-, 876.
Myelocyte of Ehrlich, 669.
Myles on sinusitis, 1009.
Myocarditis, alcoholic, 132; chronic, 138; fibrous, 134; tuberculous, 678.
Myocardium, diseases of, 138.
Myoma of the choroid, 924; of the ovarian ligament, 664.
Myomohysterectomy, 620.
Myopia, congenital, predisposition to, 897; operation in, 898; pathogeny of, 897.
Myosarcoma of the ovary, 664.
Myositis, purulent posttyphoid, 76.
Myringitis bullosa, 962.
Myxedema, 89; eye in, 947; infantile, 781; protonuclein, 825; thyroid extract in, 89, 824, 1104.
Myxoma of the larynx, 1025.

Naegeli-Akerblom on pneumonia, 114.
Nævus unius lateris, 1063.
Nails, diseases of, 1084.
Nammack on acephalic omphalosite, 467; on leukemia, 102.
Nanavatty on cataract, 936.
Nanjaba on malarial fever, 57.
Nannotti and Baciocchi on peritonitis, 275.
Narcolepsy in liver-disease, 182.
Nares, bacteria in, 998; stenosis of, 1006.
Nasal antiseptics, 996; catarrh in children, 787; chambers and cretinism, 998; diphtheria, primary, 100; disease, eye in, 950; diseases, trigeminal neuralgia and, 1002; douche, 997; duct, stricture of, 943; mucosa, anatomy, 996; pain, sodium chlorid in, 1003; polypus and sarcoma, 1004; tachycardia from, 1004; sarcoma, 1005; septum, bleeding tumor of, 1005; papilloma of, 1004; perforation of, 1007; ulceration of, 1007; splints, 1007; spurs, electrolysis of, 1007; syphilis, 1006; tuberculosis, 1006.
Nash on otitic sinus-phlebitis, 990.
Nason on enuresis, 1116.
Nasopharynx, adenoid vegetations in, 968, 1010; catarrh of, 1010; tuberculosis of, 1010; vertigo from, 1011.
Nasstinkoff on influenza, 723.
Natanson on retinal hemorrhage, 926.
Nature of eosinophile cells, 671; of fever, 67.
Nauheim treatment, 135.
Nauwerck on gastric ulcer, 165, 692.
Neale on scurvy, 106.
Nearro on epilepsy, 813.
Necrosis, fat-, 183; of the middle turbinated, 1009.
Neebe on leg-ulcers, 416.
Neglected shoulder-presentation, 532.
Negro on sciatica, 819.
Neisser on bacteria, 712; on chancroid, 1099.
Nélaton on curettage, 603.
Nencki and Javorski on apolysin, 1108; on epilepsy, 819.
Nephrectomy, 413; partial, 412.
Nephritis, acute, from shock, 798; amaurosis in, 192; from cantharidal vesication, 194; cramps in, 192; diagnosis, 193; followed by eczema, 191; etiology, 191; fever in, 193; hemorrhagic, 192; hemorrhagic, in typhoid fever, 21; leukocytes in the urine in, 193; in the newborn, 548, 798; phlebotomy in, 194; in pregnancy, 470; salol in, 194; and skin-affections, 192; due to staphylococcus pyogenes albus, 191; suppurative, 191; suppurative, etiology, 701; symptoms, 192; treatment, 194.
Nephrolithotomy, 415.
Nerve-cells and psychic phenomena, 1152; regeneration of, 1180; -centers, syphilis of, in children, 793; -deafness, 973; -exhaustion in women, 551; hypoglossal, 1153; -lesions in herpes zoster, 1038; optic, decussation of, 1155; diseases of, 930; trifacial, 1152.
Nerves of the diaphragm, 1153; superficial, of the head, 1153; sympathetic, 1180; trophic, 1180; vasomotor, 1166.
Nervous biliary colic, 182; diseases, 804; lesions in diphtheria, 755; palpitations, 139; sequelæ after typhoid fever, 24; system, anatomy, 1151; diseases of, 382, 684; physiology of, 1178.
Nettle, stinging, 1120.
Nettleship on blindness, 934; on glaucoma, 923.
Neuber on bone-cavities, 370; on joint-tuberculosis, 375.
Neumann on carcinoma uteri, 631; on degeneration of connective tissue in inflammation, 741; on distention of the fetal abdomen, 533; on glycosuria, 187; on jaundice, 175; on kyphosis lumbalis, 512; on puerperal bradycardia, 544; on puerperal osteomalacia, 544; on rachitis, 778; on red blood-corpuscles, 1162.
Neuralgia, 817; cocain in, 818; removal of the Gasserian ganglion for, 384; renal, 415; resection of Meckel's ganglion for, 384; retrobuccal operation, 384; trigeminal, 818; and nasal diseases, 1002; in women, 552.
Neurasthenia in women, 551.
Neuritis, alcoholic, and tuberculosis, 829; from bicycle-riding, 831; of intracranial origin, 933; mercurial multiple, 827; multiple, 829; in children, 795; in pregnancy and childbed, 828; optic, 932, 992; in locomotor ataxia, 854; following pneumonia, 828; with spinal-cord disease, 830.
Neuroglia, 1151.
Neuroglioma of the corpus callosum, 689.
Neuroses, cardiac, 139; hemoglobin in, 93; pulmonary, 116; reflex, 819; of the skin, 1059.
Neurotabes from diphtheria, 828.
Neurotic disturbances of the stomach, 161; vomiting, 811.
Neurotomy, opticociliary, 921.
Neusser on the Röntgen rays, 424.
Nevus, treatment of, 265.
New antiseptics, 210.
Newborn, bacteria in the intestine of, 750; blood of, 727; conjunctivitis of, 913; diseases of, 750; gonorrheal arthritis in, 754; inanition fever in, 547, 751; jaundice in, 549; nephritis in, 548, 798; ophthalmia in, 549; pathology of, 546; physiology of, 546; respiration in, 547; skin-diseases in, 549; tubercle-bacilli in the blood of, 716; vaginal secretion in, 548.

Newcomb on anesthesia, 996; on guaiacol, 1122.
Newman on laryngeal tuberculosis, 1026.
Newsholme on rheumatism, 71.
Newton on acetanilid-poisoning, 1101; on malarial fever, 52.
Nichols on delivery of the placenta, 508; on extrauterine pregnancy, 494; on fluids, 1190; on variola, 47.
Nicoladoni's operation, 355.
Nicolaier on urotropin, 1145.
Nicolle on chancroid, 1098.
Nicoulin, 1128.
Niebergall on uterine prolapse, 605.
Niemann on tubercle-antitoxin, 731.
Nieznamoff on trachoma, 915.
Night-blindness, congenital, 892.
Nijhoff on placenta prævia, 483.
Nikiforow on infectious diseases, 703.
Nipple, eczema of, 255.
Nitric acid in nevus, 265.
Nitrogen in the sputum in tuberculosis, 34.
Nitrogenous metabolites, 1173.
Nitroglycerin, 1128; in biliary colic, 182; in optic atrophy, 935.
Noble (C.) on the ligature in abdominal section, 65.
Noble (G. H.) on extrauterine pregnancy, 495.
Nochard on mammary abscess, 214; on tuberculosis, 32.
Nocturnal enuresis, 796, 831.
Nodes, teacher's, 1029.
Nodosities, epithelial, of Ferreol, 73.
Noer on placenta prævia, 483.
Nolterius on acute otitis media, 966.
Nomenclature, anatomic, 1146.
Nonabsorbable sutures in hernia, 284.
Nondiphtheric angina, bacteriology of, 691; membranous angina in children, 789.
Noninfectious diseases in children, 777.
Nonne on diabetes mellitus, 84, 684; on pernicious anemia, 850.
Nonpregnant women, vaginal secretion in, 555.
Nonvalvular affections of the heart, 133.
Norbury on lithemia, 78.
Nordmann (F.) on decidual formation, 455.
Normal growth of the eye, 892; position of the uterus, 604; salt-solution for burns, 416; on puerperal eclampsia, 518.
Norris (R. C.) on dystocia after ventrofixation, 522; on hysterectomy, 641; on labor, 502; on submammary abscess, 546; on transvaginal surgery, 644.
Norris (W. E.) on the eye in intracranial tumors, 948; on the retina, 925; on the rods and cones, 1155.
Norsa on blepharitis, 942; on leprous iritis, 919.
Norstrom on gastric massage, 163.
Northbridge on summer diarrhea, 783.
Northrup on pneumonia in children, 790; on typhoid fever in children, 769.
Norway, tuberculosis in, 32.
Nose, 996; animal parasites in, 1006; cancer of, 1008; diseases of, 995; in the embryo, 996; epithelioma of, 1008; fibromyxoma of, 1004; foreign bodies in, 1006; mycosis of, 1016; in phthisical patients, 1006; syphiloma of, 1091.
Nosoparasites, 711.
Nosophen, 1127; in eye-diseases, 944.
Nothnagel on abdominal tumors, 174.
Notkin on the thyroid, 1169.
Notthafft on carcinoma of the liver, 696; on tumors, 706.
Novaro on arterovaginal fistula, 574.
Nova Scotia, leprosy in, 1068.
Nové-Josserand on deciduoma malignum, 463.
Noyes on cataract, 938; on cretinism, 825; on keratitis, 938; on tuberculosis of the skin, 1073; on typhoid fever in children, 771.
Nuclear ophthalmoplegia, 905.
Nucleic acid, 1128.
Nuclein in exophthalmic goiter, 143.
Nucleins, 1128.
Nucleoalbumin, 189, 1129; in the urine, 1192.
Nucleoalbumose, 189.
Nucleoproteids, 1129.
Nucleus, vagal, 1154.
Nuel on albuminuric retinitis, 926.
Null on hypopyon, 940.
Nursing-bottle, 745.
Nutrition, 1168; and the teeth, 782.
Nutrose, 1130.
Nuttall and Thierfelder on intestinal infection, 172, 1176.
Nuyts on transplantation of ciliæ, 916.
Nystagmus, 893.
Nyulasy on placental inflammation, 460.

Obalinski on organopexil, 618.
Obesity, 88; thyroid extract in, 88, 1104.
Obici on diabetes mellitus, 83.
Obliquity of the forearm, 1147.
Obliteration of the appendix vermiformis, 693; of the os, 520.
Obstetric education, 450; forceps, 533; instrument-cases, 451; operations, 533.
Obstetrics, 449.
Obstructed arteries, 346.
Obstruction of the cervix uteri after curettage, 603; intestinal, 169, 302; lacrimal, 909, 910; of the pancreatic duct, 184; pyloric, 164; from gallstones, 271.
Obturator hernia, 279.
Occipitoposterior position, 528.
Occlusion of the auditory canal, 961.
Ochsner on enchondrosarcoma, 231.
Ocular muscles, anomalies of, 900; palsies, 905; parasites, 918; stethoscope, 954; syphilis, 947; tuberculosis, 919.
Oculomotor paralysis, 905; syphilitic, 776.
O'Dwyer (J.) on intubation, 1028.
Oestreich on carcinoma of the trachea, 697; on embolism, 148; on hepatic cirrhosis, 178.
Oettinger and Marinesco on Landry's paralysis, 862.
Ogilvie on tapeworm, 197.
O'Gorman on accidental hemorrhage, 483.
Ohleman on arcein, 943.
Ohls on transillumination of the antrum, 1008.
Oidium in pseudolupus vulgaris, 1073.
Oil, acetanilid, 657; camphorated, in edema of the lung, 114; of cloves in tuberculosis, 39; cod-liver, 1138; of eucalyptus in scarlatina, 769; of guaiac in the eye, 943; of sesamum, 1138; of turpentine in tuberculosis, 212.
Ointment-muslins, 1035.
Okuneff on auscultation of the mastoid, 981.
Old age, deafness of, 969.
Oleocreasote in bronchitis, 110.
Olive oil for bruises, 416; and iodoform in tuberculosis, 39.
Oliver (C.) on foreign bodies in the eye, 952; on tumor of the eyelid, 907; on wound of the eyeball, 953; and Schäfer on the pituitary body, 1170; on the suprarenal capsules, 1168; on thyreoiodin, 1106.
Oliver (J.) on extrauterine pregnancy, 491.
Oliver's tracheal tugging, 148.
Oliver (J. C.) on acute otitis media, 964.
Olshausen (R.) on ovarian cysts, 662; on primary vaginal carcinoma, 563; on puerperal eclampsia, 515.
Omboni on surgery of the lung, 329.
Omentum, great, 1150.
Omphalomesenteric duct, 169.
Onuf on fetal monstrosities, 466.
Onychomycosis, 1085.
Opacity, congenital, of the cornea, 941.
Opening the antrum, 1009; in-

voluntary, of the lateral sinus, 981.
Operation in appendicitis, 289; for carcinoma, 257; in exophthalmic goiter, 143; in myopia, 898; obstetric, 533; osteoplastic, 368; for perforation in typhoid fever, 293; during pregnancy, 479.
Operative treatment of fractures, 357; of heterophoria and heterotropia, 903; of retroflexion of the uterus, 607.
Ophthalmia neonatorum, 549, 913; nodosa, 917; purulent, 913.
Ophthalmology, 890; *x*-rays in, 953, 954.
Ophthalmometer, 955.
Ophthalmoplegia, 905.
Opium in cholera, 57; in constipation, 169; in diabetes mellitus, 86; in perityphlitis in children, 785; -poisoning, 1133; in children, 803; in summer diarrhea, 783; in tachycardia, 593; in threatened abortion, 488.
Oppenheim on aphasia, 992.
Oppenheimer on asthenopia, 902.
Oppler on pepsin, 691; on the stomach, 154; and Külz on diabetes mellitus, 82.
Optic aphasia, 949; atrophy, 934; nerve, anatomy of, 930; carcinoma of, 935; decussation of, 930, 1155; diseases of, 930; drusen in, 930; embolus of, 934; glands in, 930; tumor of, 935; neuritis, 992; edematous, 933; gonorrheal, 932; in locomotor ataxia, 854; rheumatic, 932; syphilitic, 932.
Opticociliary neurotomy, 921.
Orbit, 892; abnormalities of, 895; aneurysm of, 910; angioma of, 911; congenital glioma of, 892; dermoid cyst of, 892, 912; diseases of, 910; endothelial tumors of, 912; foreign body in, 913; infection of, 910; lymphangioma of, 911; osseous tumor of, 912; osteoma of, 912; pseudoplasm of, 911; sarcoma of, 911, 912; syphilis of, 912.
Orbital cellulitis, 910; in influenza, 911; thrombophlebitis, 911; tumors, 911.
Orchitis, guaiacol in, 380.
Orchotomy for enlarged prostate, 408.
O'Reilly on abortion, 485.
Organ of Jacobson, 1154; of the special senses, 1154.
Organism of cholera, 57; malarial, 53; of yellow fever, 58.
Organopexil, 618.
Orientation, 1181.
Origin of the stitch-abscess, 212; of uterine fibroids, 617.
Orlandi on pigment-anomalies of the skin, 1062.
Orloff on missed abortion, 481.
Orlowski on diphtheria, 757.
Ormerod on hepatic cirrhosis in children, 782; and Spicer on ophthalmoplegia, 905.
Orth on gastric ulcer, 266.
Orthmann on metrorrhagia, 589; on tuberculosis of the Fallopian tube, 659.
Orthomonochlorphenol, 1130.
Orthopedic surgery, 872; excision in, 882.
Orton on typhoid fever, 29.
Os, obliteration of, 620.
Osler (W.) on Addison's disease, 105; on arthritis deformans, 885; on erythema exsudativum multiforme, 1031; on hemiplegia in typhoid fever, 834; on malarial fever, 56; on tumor of the pylorus, 166; on typhoid fever, 20, 22, 27, 30.
Osmond and Chotbard on cervical dystocia, 519.
Osmosis and lymph-formation, 1163.
Osseous tumors of the orbit, 912.
Ossicles, excision of, 976.
Osteoarthropathy, 108; pulmonary hypertrophic, 845.
Osteochondrosis desiccans, theory of König, 884.
Osteology, 1147; and the Röntgen rays, 428.
Osteoma of the orbit, 912.
Osteomalacia, 87; bone-marrow in, 87, 88; ovaries in, 666; puerperal, 544.
Osteomyelitis, acute, 370, 394; multiple, 370; recurrent, 370; tuberculous, iodoform-glycerol in, 878.
Osteoplastic amputations, 226; brachioolecranon amputation, 226; metacarporadiocubital amputation, 228; operation, 368.
Osteopsathyrosis, 780.
Osteotomy for vicious ankylosis, 881.
Osterloh on emphysema after abdominal section, 657.
Ostermann on chinosol, 1113.
Ostitis, juxtaarticular tuberculous, 881.
Ostium tubæ, accessory, 537.
Ostowsky on lymph-formation, 1165.
Oswalt on iridocyclitis, 919.
Otis on suppurative adenitis, 217; on tuberculosis, 32.
Otitic cerebral abscess, 991; complications, 982; cerebellar abscess, 992; facial paralysis, 967; meningitis, 994; sinus-phlebitis, 990.
Otitis, acute, mastoiditis after, 964; of measles, 964; influenza, 963; interna, pilocarpin in, 971; in measles, 765; media, acute, and adenoids, 963; meningitis after, 964; in pneumonia, 962; purulent leptomeningitis after, 964; secondary infection after, 965; septicemia from, 965; treatment, 965; in typhoid fever, 962; media, chronic catarrhal, 968; purulent, 974; in infancy, 963.
Otogenous pyemia, 990.
Otology, 957.
Otorrhea, 974; tuberculous, lactic acid in, 976.
Ott on the brain, 1180; on uterine fibroids, 617.
Ovarial parasites, rudimentary, 706.
Ovarian cystoma, 660; and glycosuria, 661; growth of, 662; heredity in, 662; infection of, 662; papillary, 662; strangulation of, 661; torsion of, 661; dermoid, 663; ligaments, myoma of, 664; pregnancy, 500; tumors in pregnancy, 479; solid, 664.
Ovariectomy in pregnancy, 480.
Ovariotomy, 660.
Ovary, abscess of, 666; anomalies of, 666; calcification of, 650; carcinoma, 664; cyst of, 660; diseases of, 660; fibrosarcoma of, 664; hernia of, 664; micrococcus lanceolatus in, 666; myosarcoma of, 664; in osteomalacia, 666; papillary cyst of, 662; prolapse of, 665.
Ovaries, tuberculosis of, 45.
Overdistended bladder in labor, 521.
Ovio on accommodation, 898; on foreign bodies in the eye, 953.
Owen (E.) on cleft palate, 350; on the spine in children, 876.
Owens on abdominal section, 650.
Oxalic acid in the urine, 187.
Oxaluria, 186, 1190; Cantani's diet in, 187.
Oxycyanid of mercury, 210.
Oxygen after ether-narcosis, 247; -gas and ether, 246; inhalations in anemia, 95; in pseudoleukemia, 104.
Oysters, poisoning by, 67.
Oyster-shucker's keratitis, 939.
Ozena, bacteriology, 1000; etiology of, 696, 1000; treatment, 1000.

Paal on dietetics, 1174.
Pachymeningitis cervicalis hypertrophica, 854.
Paci on intractable vomiting, 269.
Packard on cardiac anomalies, 786; on gout, 80.
Pässler and Romberg on infectious fevers, 138.
Page on fibrosarcoma of the ovary, 664; on fracture-dislocation of the spine, 397; on hydatid cysts of the liver, 180; on results of major amputations, 223; on the vermiform appendix, 290.
Pagenstecher on hemothorax, 327; on mesenteric cysts, 174.
Paget (S.) on carcinoma of the

breast, 261; on parotitis, 350.
Paget's disease of the breast, 261.
Pagnini on salicylic acid, 944.
Pailhas on Landry's paralysis, 864.
Pain in gall-stones, 181.
Pains, growing, 876; nasal, 1003.
Painless tumor of the spinal cord, 854.
Palamidessi on fowl-cholera, 64.
Palate, cleft, 350, 1013; diseases of, 350; lupus of, 1025; soft, tuberculosis of, 43.
Palladium bichlorid in local tuberculosis, 221; catgut, 207.
Palma on acetonuria, 188.
Palmar abscess in typhoid fever, 20.
Palmer on anarcotin, 1102.
Palpation, lumboabdominal, 640; in pelvic disease, 638.
Palpitation, nervous, 139.
Palsies after diphtheria, 762.
Palsy, birth-, 822; ocular, 905; syphilitic oculomotor, 776.
Panas on blindness, 950; on incoordination of the centers, 904; on lacrimal diseases, 909; on pseudoplasm of the orbit, 911.
Pancreas, carcinoma of, 184, 343, 696; cyst of, 311; development of, 1151; diseases of, 183, 311; rupture of, 311; sarcoma of, 696.
Pancreatic duct, obstruction of, 184; lesions and diabetes, 83; medication in diabetes mellitus, 87.
Pancreatitis, acute, 183; chronic, 184.
Pándi on reflex action, 1179.
Pane on septicopyemia, 62.
Panhysterectomy, 682.
Panse on acute otitis media, 966; and Leutert on caries of the ear, 977.
Pansini on typhoid fever, 23.
Papillary cyst of the ovary, 662; ridges of fingers and toes, 1158.
Papillitis, 932; in tetany, 838.
Papilloma of the buccal mucosa, 1012; multiple, of the larynx, 1024; of the nasal septum, 1004.
Papuloulcerative, follicular, hyphomycetic skin-disease, 1081.
Paquin's antitubercle-serum, 40, 41; treatment of tuberculosis, 40, 41.
Paracentesis, albuminous expectoration after, 118.
Parachlorphenol, 1130; as an antiseptic, 211; in tuberculous laryngitis, 1026.
Paraldehyd in asthma, 1130.
Paralysis, acute ascending, 861; bulbar, 834, 847; crossed, 836; elective sensory, 831; general, blood in, 93; etiology, 867; glossolabiolaryngeal, 834; infantile, 794; Landry's, 686, 861; laryngeal, 1028; oculomotor, 905; otitic facial, 967; in pertussis, 773; of the superior rectus, 900.
Paralytic deformities, 886.
Paranuclein, 1129.
Paranucleoproteids, 1129.
Parapancreatic abscess, 183.
Parasites, animal, 196; animal, in the nose, 1006; and carcinoma, 628, 629; intestinal, in children, 786; in malarial fever, 52; of molluscum contagiosum, 1060; ocular, 918; rudimentary ovarial, 706; of varicella, 1047.
Parasitic chyluria, 678; sycosis, 1081.
Parasitism of carcinoma, 707.
Parenchymatous keratitis, 939.
Paresis, juvenile, 868.
Paretic dementia, early, 868.
Parinaud on optic neuritis, 933; on hysteria, 945.
Pariser on the gastroscope, 156; on gastric ulcer, 267; on nervous biliary colic, 182.
Parietal peritoneum as a suture material, 209.
Parisotti on subconjunctival injections, 942.
Park (R.) on acute infectious disease of bone, 884; on insufficiency of the eye-muscles, 902; on malignant tumors, 254; on mustard as an antiseptic, 211; on resection of the pneumogastric nerve, 383; on spina bifida, 382; on stricture of the urethra. 397; on tuberculous osteomyelitis, 878.
Parker (R.) on absence of the abdominal muscles, 1159; on cretinism, 827; on hepatic cirrhosis, 177; on hernia in children, 280, 282; on infantile myxedema, 89, 781; on inherited syphilis, 1089.
Parkinson on Addison's disease, 105.
Parmenter on contusion of the lungs, 332; on forced artificial respiration, 250.
Parosmia, 1003.
Parotid gland, swelling of, 350.
Parotitis, 350; and gastric ulcer, 166.
Paroxysmal tachycardia, 139.
Parry on glycosuria, 780.
Parsons on typhoid fever, 24, 371.
Partial thyroidectomy, 1019; nephrectomy, 412.
Partridge on diabetes in pregnancy, 471.
Parvin (T.) on anesthesia, 247.
Paschen on carcinoma of the uterus, 626.
Passow on gliosarcoma of the quadrigeminal body, 993; on otitic sinus-phlebitis, 990.
Patein on ether, 246.
Patek on the Brand method, 28.
Patella, fractures of, 363; slipping, 883; subcutaneous wiring of, 363.
Patency of Gärtner's duct, 563.
Patent ventricular septum, 144.
Patera on pernicious anemia, 100.
Pathogenesis of abdominal fat-necrosis, 696; of carcinoma, 626; of appendicitis, 170.
Pathogenic anaërobic bacillus of the intestine, 714; yeast, 711, 726.
Pathologic technic, 736.
Pathology, 667.
Paton (N.) on Cesarean section, 537; on fat, 1173; on the liver, 1170.
Patrick (H. T.) on hysteria, 805, 807.
Patterson on summer diarrhea, 784.
Paul on excision of the rectum, 326; on gastric ulcer, 268; on hip-joint amputation, 233; on intussusception, 309; on ipecacuanha alkaloids, 1123.
Paulocardia, 139.
Pavia on boxwood, 1110.
Pavy on the liver, 1170.
Pawlik's method, 581.
Pawlowsky and Maksutow on immunization, 733.
Péan on incontinence of urine, 576; on surgery of the lung, 328; on tuberculosis, 32.
Péan's morcellation, 621, 649.
Pearce (F. S.) on atypical muscular dystrophy, 823.
Pearse on rheumatism, 73.
Pearson on puerperal hyperpyrexia, 540.
Pease (C.) on anemia, 95.
Péchin on entropion, 907; on the eye, 951; on teeth, 950.
Peck on gangrene of the ear, 958.
Pedatrophy, kidneys in, 700.
Peddie on color-blindness, 1182.
Pediatrics, 744.
Pedicle in myomohysterectomy, 622.
Peliosis, 1057.
Pellizari on syphilis, 1094.
Pellizari's treatment, 1085.
Pellizzi on epilepsy, 813.
Pelvic disease, 638; bacteriology in, 639; and mental disorders, 552; palpation in, 638; vaginal incision for, 644; hematocele after labor, 544; hematoma after abdominal section, 656; suppuration in pregnancy, 476; surgery, conservative, 654; tuberculosis, 45; viscera, diseases of, 638, 641.
Pelviotripsy, 521.
Pelvis, contracted, 511; female, in primitive races, 433; iliofemoral, 514; Javanese, 453; rachitic, 514.
Pelzer's method of inducing abortion, 489.
Pembrey and White (H.) on animal heat, 1173.

Pemphigoid eruption of cutaneous tuberculosis, 1040.
Pemphigus, acute, 1039.
Penis, diseases of, 397; double, 1157; malformation of, 1156.
Penrose (C. B.) on abdominal hysterectomy, 621; on bacteriology in pelvic disease, 639; on congenital erosion of the cervix uteri, 571; on drainage, 652; on hysterectomy in puerperal sepsis, 644: on the ligature in abdominal section, 651; on the position of the uterus, 604; on ureterovaginal fistula, 574; and Beyea on tuberculosis of the Fallopian tube, 659.
Pentose in the urine, 190.
Pepper (W.) on pernicious anemia, 98; on tuberculosis, 36; and Stengel on intrathoracic tumors, 120, 704; on stones in the common duct, 316.
Peppermint in epilepsy, 815.
Pepsin, activity of, 154, 163; in gastric diseases, 691.
Peptonuria, 1192.
Perceptions, subjective visual, 929.
Percussion, auscultatory, 123.
Perforation during curettage, 603; duodenal, 167; gastric, 167, 266; intestinal, in typhoid fever, 28, 292; of intestine by a polyp, 693; of the nasal septum, 1007; spontaneous, of the medial plate of the mastoid, 979; traumatic, of the membrana tympani, 961; of the uterus after abortion, 486.
Pericardial adhesions, 122; effusion, 121.
Pericarditic pseudocirrhosis, 177.
Pericardium, diseases of, 121; puncture and incision of, 338; stab wound of, 339.
Peridental membrane, sarcoma of, 690.
Perier on laryngotomy, 332.
Perihepatitis, chronic, 694.
Perimeter, 955.
Perineal drainage in cystitis, 402; laceration, 520; prostatectomy, 410; section, 397.
Perineorrhaphy, 568.
Periodic vomiting, 161.
Perioral eczema, 1033.
Peripheral disease, sensory dissociation in, 831.
Periphlebitis of the jugular from mastoiditis, 964.
Peristalsis after abdominal section, 657.
Peritoneal adhesions, 169, 655; exanthem in measles, 765; fossæ, 1150; tuberculous, 274.
Peritoneum, diseases of, 173, 274; parietal, as a suture material, 209.
Peritonism, 806.
Peritonitis, fetal, 479; gonorrheal, 696; local, 173; septic, 277; tuberculous, 44, 223; in typhoid fever, 23.
Perityphlitis in children, 785.
Perkins on anencephalus, 467; on retinoscopy, 955.
Permanent hemostasis, 432.
Pernet and Bulloch on acute pemphigus, 1039.
Pernicious anemia, 98; pathology of, 674; spinal cord in, 850; malarial fever, 53; skin-disease, 1046; vomiting of, in pregnancy, 468.
Peron on tuberculosis, 44.
Perrin on Duhring's disease in pregnancy, 1041.
Pershing on blepharospasm, 906.
Persistent canal of Cloquet, 892; ductus omphalomesentericus, 169; hyaloid artery, 892.
Pertussis, 773; antipyrin in, 801, 1102; antispasmin in, 1108; asaprol in, 802; bacteriology of, 697; bromoform in, 773; ciliated ameba in, 774; hemiplegia in, 773; phenocoll hydrochlorate in, 774; sputum in, 697; vaccination in, 774.
Peru, balsam of, in scabies, 1049.
Pes and Gradenigo on otorrhea, 974.
Pestana and Bettencourt on syringomyelia, 686.
Peters on ovarian cyst, 660.
Peterson on epilepsy, 814; on the Röntgen rays, 424; and Bailey on cretinism, 781, 827.
Petresco's method, 114.
Petrini on neuritis, 830.
Petroleum disinfectant, 1131.
Petruschky on the streptococcus, 737.
Pettyjohn on chloroform-anesthesia, 243.
Pfannenstiel on carcinoma of the uterus, 626; on ichthyosis uteri, 625; on papillary cyst of the ovary, 662; on pregnancy in uterus didelphys, 477.
Pfeiffer on the antibodies of cholera and typhoid fever, 729; on cow's milk, 746; on gout, 79; on influenza, 723; on oxaluria, 186; on polymyositis, 74; on vaccinia, 48; on bacillus, 51; and Kolle on the typhoid-bacillus, 728; and Proskauer on immune animals, 730.
Pfingst on sarcoma of the lacrimal gland, 909; on tumor of the cornea, 941.
Pfister on cocain-poisoning, 1114.
Phanomenoff on size of the fetus, 532.
Pharmacology, 1100; of ipecacuanha alkaloids, 1123.
Pharyngeal hemorrhage, 1016.
Pharyngitis, chronic, 151; guaiacol in, 996; treatment, 1017.
Pharyngotherapy, 1016.
Pharyngotomy, subhyoid, 332; transhyoidean, 332.
Pharynx, chronic spasm of, 1017; diseases of, 151; syphilis of, 1016.
Phear on presystolic murmurs, 128.
Phelps (C.) on congenital dislocation of the humerus, 373; on fracture of the patella, 367; on iodoform-injections, 879; on vomiting during anesthesia, 250.
Phelps's method, 339.
Phenacetin-poisoning, 1131; in septicemia, 63; in typhoid fever, 30.
Phenocoll in pertussis, 774; in pregnancy, 485.
Phenol hydrochlorate in burns, 416; in chancroid, 1099; in gonorrheal endometritis, 557; in malarial fever, 57; on the skin, 1043; in tuberculous adenitis, 1017.
Phenomena, Ménière's, 969; of menstruation, 586; psychic, and the nerve-cells, 1152.
Phenomenon, diaphragm-, 107.
Phenosalyl in labor, 503.
Phenylchinolin, 1135.
Phenylhydrazin test for sugar, 1193.
Phenylhydroxylamin - poisoning, 1132.
Philadelphia, death-rate from tuberculosis in, 31.
Phillips on corneal ulcer, 940; on valvular cardiac disease in pregnancy, 470.
Phimosis, 797.
Phlebotomy in nephritis, 194; red, 858; white, 858.
Phlegmasia alba dolens, 541.
Phlegmonous gastritis, 160.
Phloridzin-diabetes, experimental, 82.
Phlyctenular conjunctivitis, 916.
Phonendoscope, 107.
Phoses, 929.
Phosphaturia, 185.
Phosphin, 1136.
Phosphorism, 1133.
Phosphorus in lupus erythematosus, 1070; -poisoning, 1133.
Photofluoroscope, 1147.
Photometer, 935, 954.
Photoscope, 420.
Photostat, iris as, 896.
Phrenic nerve, division of, 383.
Phthisis, acute, 33; incipient, 34.
Physiology, 1161.
Pic on the spinal cord, 861.
Piccola on the canal of Cloquet, 892; on carcinoma of the lacrimal gland, 909.
Pichevin on curettage, 603.
Pichler on leukocytes, 93.
Pick on nephritis, 192; on pericarditic pseudocirrhosis, 177.
Pickering on coagulation of the blood, 1162.
Picow and Ramond on pseudoleukemia, 103.
Picric acid for burns, 417; test for sugar, 1194.

Picrotoxin in exophthalmic goiter, 143.
Piedra nostras, 1084.
Pierce on nasal sarcoma, 1006.
Piersol on obliteration of the appendix vermiformis, 693.
Piersoll on spermatozoa, 452.
Pierson (S.) on typhoid fever, 19.
Pigment-adenoma of the conjunctiva tarsi, 916; -anomalies of the skin, pathology of, 1062; urinary, 1191.
Pigmentary diabetes, 84.
Piles, Whitehead's operation for, 326.
Pilgrim on presbyopia, 899.
Pill, Blaud's, in chlorosis, 97.
Pilliet on tubal pregnancy, 490.
Pilocarpin in diphtheria, 764; in diseases of the eye, 942; in glaucoma, 923; in labyrinthitis, 971; in Ménière's disease, 969; in otitis interna, 971; in puerperal eclampsia, 518; in tetanus neonatorum, 752; in pneumonia, 113; in xerostoma, 1012.
Pinard on puerperal sepsis, 543; on secondary abdominal pregnancy, 498; on symphysiotomy, 535.
Pincus on steam as a hemostatic, 589.
Pine on guaiacol, 234.
Pineles on asthenic bulbar paralysis, 848; on homolateral hemiplegia, 833.
Piorkowski on urine culture-media, 737.
Piper and Schnaase on vaccination, 48.
Piperazin, 1133; in gout, 81; in the uric-acid diathesis, 186.
Pithecanthropus erectus, 1159.
Pitres on pleurisy, 118.
Pitres' plumb-line sign, 118.
Pittfield on the staining of flagella, 737.
Pitts on otitic sinus-phlebitis, 990.
Pituitary body, 1170.
Pityriasis alba atrophicans, 1084; pilaris rubra, 1079, 1080.
Piutti (A.) on pyrantin, 1135.
Place, Kiesselbach's, 1005.
Placenta, 456; adhesion, 460; delivery of, 508; expulsion of, 507; inflammation of, 459; pathology of, 459; prævia, 483, 484; premature detachment of, 483; retained, after abortion, 488; squeezing out of, 507; streptococcus infection through, 457; tuberculosis of, 460.
Placental blood and tuberculosis, 33; circulation, 456; cross-birth, 508; polypus, 488; transmission, 457; version, 508.
Plague, bacillus of, 59; bubonic, 59; brain-symptoms in, 60.
Plasma-cells, 1160.
Plaster-muslin, 1035; -of-Paris bandages, removal of, 203.
Plastic cyclitis, 919; iritis, acute, 919; surgery, 416.
Playfair on puberty, 583.
Plehn on malarial fever, 55.
Plenge's method, 739.
Plethysmograph, 1167.
Pleura, tuberculosis of, 44.
Pleuræ, diseases of the, 107.
Pleural exudates, 117.
Pleurisy, 117, 118; etiology, 699; and gonorrhea, 118, 699.
Pleuritis, 117, 699.
Plexus buccalis, 1154.
Plimpton on excision in orthopedics, 882.
Plowright on catarrhal jaundice, 175.
Plucker on splenopexy, 314.
Plumbism, 80.
Plumb-line sign, 118.
Plummer on the middle meningeal arteries, 386.
Pneumococcus, 113; in conjunctivitis, 914; in ocular pathology, 914.
Pneumogastric nerve, division of, 383.
Pneumonia, 111; acute lobar, in diabetes mellitus, 84; after etherization, 250; acute otitis media in, 962; antipyrin in, 801; arthritis in, 112; aspiration-, 698; bacteria in, 111; in children, 789; complications and sequels, 112; croupous, arthopathies of, 698; atypical, 697; dangers in, 112; digitalis in, 114; digitoxin in, 114, 1116; etiology, 111; after grippe, 114; in influenza, 52; inhalation-, 250; leukocytes in, 92, 93, 112; lobular, 698; muscular irritability in, 111; neuritis after, 828; pilocarpin-treatment, 113; relapses in, 113; statistics of, 111; streptococcus-, 697; subcutaneous abscesses in, 113; Sziklai's treatment, 113; thrombosis in, 113; treatment, 113.
Pneumopaludism of the apices, 55.
Pneumoperitoneum, 660.
Pneumothorax, 118, 119.
Pneumotomy, 330.
Poggi on burns, 417.
Points, diplopsic, 903.
Poison in expired air, 1185; action of, on the kidney, 700.
Poisoning by acetanilid, 1101; by alcohol in children, 802; by belladonna, 1109; bromic, 1110; by carbolic acid, 1111; by carbonic-oxid, 1178; by chromic acid, 1113; by cocain, 1113; by coffee, 1115; cyanid-, 1115; by eggs, 67; by glycerin in children, 802; by lactophenin, 93; by lead, 932; by leukomains, 78; by opium, 1133; by opium in children, 803; by oysters, 67; by phenacetin, 1131; by phenylhydroxylamin, 1132; by phosphorus, 1133; by quinin, 1137; by stramonium, 931.
Polaillon on curettage, 603.
Polak on fistula after abdominal section, 656; on puerperal eclampsia, 514, 516; on uteroabdominal fistula, 575.
Poliakoff on suppuration, 713.
Poliomyelitis, anterior, in children, 794; in diabetes, 684.
Politzer on carcinoma of the mastoid, 981; on chronic otorrhea, 975; on deafness of old age, 969; on exostosis of the ear, 960; on extraction of the malleus, 976; on intratympanic surgery, 972; on malformations of the auricle, 958; on perforation of the membrana tympani, 961; on sclerosis of the ear, 971.
Polk on transvaginal surgery, 644.
Pollack on acute otitis media, 965.
Pollatschek on diarrhea, 169.
Pollution of rivers, 1185.
Polyak on nasal tuberculosis, 1006.
Polycythemia rubra, 91.
Polyesthesia, 811.
Polymicrobic infection, 742.
Polymyositis, 74, 75.
Polyneuritis, 687; puerperal, 545.
Polyneurotic psychoses, 864.
Polyokoff on cataract, 937.
Polypoid hypertrophy of the tonsils, 1015; lipoma of the larynx, 1022.
Polypus, perforation of intestine by, 693; nasal, 1004; placental, 488.
Polyuria, pretuberculous, 35.
Pomeroy on symphysiotomy, 535.
Pomorski on melena neonatorum, 754.
Poncet on anesthesia, 242; on tracheotomy, 250.
Ponfick on abdominal fat-necrosis, 696; on hemorrhage, 346.
Poole on summer diarrhea, 784.
Pooley on optic neuritis, 992.
Popper on Gärtner's mixture, 747.
Porak on retention of fetal urine, 533; on valvular cardiac disease in pregnancy, 469.
Porro operation, 536.
Port on septicemia, 62.
Porta on cyst of the thyroid, 351.
Porter on the heart, 1167; on vasomotor nerves, 1166.
Portwine marks, 265.
Posey (W. C.) on the retina, 925.
Position of the fetus in utero, 453; of the kidney, 1156; normal, of the uterus, 604; occipitoposterior, 528; of the stomach, 157; of umbilicus, 639; Walcher's, 512.
Posner on nosophen, 1128.

Pospelow on acne of the face, 1082.
Posselt on dextrocardia, 144.
Postclimacteric endometritis, 601; hemorrhage, 631.
Postdiphtheric cycloplegia, 918.
Postmortem Cesarean section, 528.
Postnasal catarrh, etiology, 1010.
Postoperative intestinal obstruction, 303.
Postpartum hemorrhage, 544.
Postserotherapic eruptions, 763.
Posttyphoid bone-lesions, 371; myositis, 76.
Potain and Vaquez on cardiac hypertrophy, 787.
Potassium acetate eruption, 1053; bichromate in gastralgia, 163; bromid in diabetes mellitus, 86; in epilepsy, 1111; in exophthalmic goiter, 143; in glaucoma, 923; in tetanus neonatorum, 753; cantharidate in lupus vulgaris, 1072; chlorid in metabolism, 1112; iodid in acute endocarditis, 126; in actinomycosis, 1055; in cerebrospinal meningitis, 837; in condylomata of the trachea, 1030; in disease of the larynx, 1026; in enuresis, 796; eruption from, 1051; in quinin-amblyopia, 931; in surgical tuberculosis, 222; in xerostoma, 1012; nitrate in burns, 417; permanganate in conjunctivitis, 916; in gonorrhea, 557; in lithemia, 79; in opium-poisoning, 1133; in phosphorus-poisoning, 1133; in purulent ophthalmia, 942; in skin-diseases, 1087; in tuberculosis, 39; in vulvitis, 554; in vulvovaginitis, 797; tartrate in diabetes mellitus, 86
Potel on the weight of premature infants, 745.
Pott on cardiac disease, 127.
Pott's disease, 394; wagon for, 876.
Potter on obliquity of the forearm, 1147.
Pottien on cholera nostras, 693.
Potts (C. S.) on epilepsy, 814.
Poulet on pneumonia, 114.
Poupinel on vaginal cyst, 560.
Powder-burns, 418; Cantani's, 1145.
Powell on pneumonia, 112.
Power (D.) on cystic lymphangioma, 348; on the eye in hysteria, 945; on mammary abscess, 215; on sarcoma of the vagina, 800; on surgical diseases of children, 875.
Pozzi (M.) on dysmenorrhea, 590; on inversion of the uterus, 527.
Preble on hepatic cirrhosis, 178.
Precocious menstruation, 586; motherhood, 453.
Predisposition, congenital, to myopia, 897.
Pregel on intestinal digestion, 1176; on the testicle, 1170.
Pregnancy, abdominal, 498; albuminuria in, 470; albuminuria retinitis of, 944; bullet-wound of the uterus in 478; cornual, 497, 508; course of, in young primiparæ, 455; dermoid cyst in, 479; and diabetes, 471; diagnosis of, 458; diet during, 459; in a double uterus, 476; Duhring's disease in, 1041; endometritis in, 475; and exophthalmic goiter, 470; extrauterine, 490; with fibromyoma of the uterus, 480; and gonorrhea, 474; heart in, 454; and heart disease, 127; hygiene in, 459; and infectious diseases, 473; lupus erythematosus disseminatus in, 1072; malaria in, 485; manipulation in, 458; mental disease in, 471; metritis in, 475; multiple, 529; multiple neuritis in, 828; nephritis in, 470; ovarian, 500; ovarian tumors in, 479; ovariectomy in, 480; operations during, 479; pathology of, 468; pelvic suppuration in, 476; pernicious vomiting of, 468; phenocoll in, 485; physiology, 451; pleurisy in, 118; prolongation of, 481; quinin in, 485; rectal examination in, 505; sepsis during, 474; small-pox in, 473; spontaneous rupture of the uterus in, 477; streptococcism in, 474; traumatism during, 478; tubal, 490; and tuberculosis, 473; tuboabdominal, 498; twin, 529; typhoid fever in, 19, 24; with unruptured hymen, 520; uterine displacements in, 475; in uterus didelphys, 477; vesical calculus in, 480; x-rays in, 458.
Premature detachment of the placenta, 483; infant's, weight of, 745; rupture of the membranes, 461.
Prendergast on nocturnal incontinence, 831.
Prentice on the iris, 896.
Prentiss and Morgan on anhalonium Lewinii, 1104.
Preparation of chromicized catgut, 209.
Presbrey on homicide, 1184.
Presbyopia, 899.
Prescott on pneumonia after etherization, 250.
Presentation of the face, 532; of the shoulders, 532.
Preservation of virulent cultures of the streptococcus, 737.
Pressure, atmospheric, and the hip-joint, 881; intragastric, 156; -jaundice, 176.
Prestiqs on albuminuria, 189.
Preston Retreat, labor in, 502.
Presystolic murmurs, 128.
Pretuberculous albuminuria, 35; polyuria, 35.
Preuschen on vaginal cyst, 560.
Priapism in leukemia, 101.
Pribram on exophthalmic goiter, 142, 1018.
Price (A. D.) on puerperal eclampsia, 514.
Priestly on scarlatina, 769.
Primary actinomycosis of the lung, 698; carcinoma of the vagina, 563; mastoiditis, 978; nasal diphtheria, 1000.
Primiparæ, young, pregnancy in, 455.
Primitive races, female pelvis in, 453.
Primrose on tuberculous glands, 221.
Prince on abdominal section, 650; on typhoid fever, 26.
Prism-exercise, 903.
Prismometer, 956.
Pritchard on acute otitis media, 965, 967; on bullet-wound of the pregnant uterus, 478; on hyperostosis of the ear, 960; on otitic cerebral complication, 986; on purulent otitis media, 974; on reflex labyrinth symptoms, 974; on turbinotomy, 972; and Barr on Ménière's disease, 969.
Probing for bullets, 435.
Procedure, Credé's, 507.
Processes, alveolar, tuberculosis of, 716,
Prochownick on treatment of extrauterine pregnancy, 501; on tubal abortion, 497.
Procreation of sex at will, 452.
Proegler on tetanus, 843.
Professional syphilis, 1092.
Progressive muscular atrophy, 684; after diabetes mellitus, 84.
Projectiles and rifles, 436.
Prolapse, funic, 533; of the laryngeal ventricles, 1021; of the ovary, 665; of a pregnant uterus, 475; of the uterus, 605.
Prolongation of pregnancy, 481.
Prophylaxis of influenza, 52; of tuberculosis, 31.
Prostate, atrophy of, 1170; diseases of, 406; enlargement of, 399; hyertrophy of, 406.
Prostatectomy, perineal, 410.
Prostatic hypertrophy, 406.
Protective substances in the blood of newborn infants, 727.
Proteus vulgaris, 698.
Protonuclein in myxedema, 825.
Protozoa, 196; flagellate, in the intestines, 743; of herpes zoster, 1038; in leukemia, 101; in lipoma, 708; in the lungs, 116; in sputum, 743; and tumors, 706.
Protozoan (coccidioidal) infection of the skin, 1076.
Pruritus, 1059; anal, 327.
Prus on syringomyelia, 860.
Pryor (W.) on adherent retroposed uteri, 608; on the endometrium, 602; on gonorrhea

in women, 556; on hysterectomy, 634; on iodoform-gauze, 206.
Przewoski on eosinophile cells, 671.
Pseudencephalus, 467.
Pseudochancre, 1098; indurated, 380.
Pseudocirrhosis, pericarditic, 177.
Pseudodiastolic murmurs, 131.
Pseudoerysipelas after atropin, 900.
Pseudoleukemia, 103, 669.
Pseudolupus vulgaris, oidium in, 1073.
Pseudomalarial attacks, 53.
Pseudomembranous conjunctivitis, 915; enteritis in children, 786.
Pseudomeningitis, hysteric, 806.
Pseudoplasm of the orbit, 911.
Pseudotrichinosis, 75.
Pseudotuberculosis, 115.
Psoriasis, 1033; uteri, 624; vulgaris in infancy, 1036.
Psorospermose folliculaire vegetante, 1078.
Psychiatry, knee-jerk in, 865.
Psychic phenomena and nerve-cells, 1152.
Psychoses of lactation, 545; polyneurotic, 864; puerperal, 545.
Pterygium, 917.
Ptosis, 908; abdominal, 323.
Puberty, 583.
Pucci on orchitis, 380.
Puech on conjunctival cysts, 916; on induction of abortion, 489; on lacrimation, 909; on myopia, 897.
Puerperal bradycardia, 544.
Puerperal eclampsia, 514; aura in, 515; chloral hydrate in, 518; chloroform in, 518; digitalis in, 519; Dührrsen's treatment, 515; fetal kidneys and spleens in, 516; induction of labor in, 519; morphin in, 518; normal saline solution in, 518; pilocarpin in, 518; spartein in, 519; tetanus after, 515; toxicity of the urine and blood-serum in, 516; venesection in, 519; veratrum viride in, 517.
Puerperal hyperpyrexia, 540; insanity, 471; osteomalacia, 544; polyneuritis, 545; psychoses, 545.
Puerperal sepsis, 538; antistreptococcic serum in, 220, 542; classification of, 538; creasote in, 543; delayed, 540; hysterectomy in, 642; intravenous injections of mercuric chlorid in, 542; local treatment, 543; streptococcus in, 540; treatment, 542.
Puerperal tetanus, 541.
Puerperant, treatment of, 509.
Puerperium, 502; conception during, 511; erysipelas in, 49; gonorrheal rheumatism in, 540; intermittent fever in, 540; multiple neuritis in, 828; pathology of, 538; witch-hazel in, 509; in young primiparæ, 455.
Pütz on hepatic-cirrhosis, 179.
Pugliese on sodium chlorid, 1113.
Pujol on twin pregnancy, 529.
Pulmonary abscess, 115; alveoli, 1156; hypertrophic osteo-arthropathy, 845; infarction after hysteropexy, 613; lymphatics, 1149; neuroses, 116; stenosis, 132; surgery, 328; tuberculosis of the aged, 34; vasomotor nerves, 1166.
Pulsating exophthalmos, 912.
Pulse in labor, 507.
Puncture and incision of the pericardium, 338; lumbar, 855; Quincke's, 792, 855, 989; vertebral, in general paralysis, 869.
Pupil, voluntary dilatation of, 813.
Pupillometer, 919.
Purch on pernicious vomiting of pregnancy, 468.
Purpura hæmorrhagica, 1058; bacillus of, 715; idiopathic, 1057; rheumatica, 1057.
Purpuric eruption after sodium salicylate, 1058.
Purulent, chronic, otitis media, 974; leptomeningitis after acute otitis media, 964; ophthalmia, 913; potassium permanganate in, 942.
Purulent otitis media and brain-disease, 974; surgical treatment, 975; post-typhoid myositis, 76.
Pustule, vaccine, on the eyelid, 907.
Pustuloderma, scrofulous, 1074.
Putnam on exophthalmic goiter, 140; on neuralgia, 818.
Putrefaction, intestinal, 172.
Putrid meat in fever, 68.
Pyelitis, 194, 414.
Pyelophlebitis after typhoid fever, 216.
Pyemia, 62; otogenous, 990.
Pyemic abscess, gonococcus in, 725.
Pye-Smith on skin-diseases in Bright's disease, 1049.
Pygopagus, 467.
Pylephlebitis after typhoid fever, 179.
Pyloralgia, 164.
Pylorectomy, 301.
Pyloric obstruction, 164; from gall-stones, 271.
Pyloroplasty, 268.
Pylorus, contractile tumor of, 166; stricture of, 268.
Pyoktanin in eye-diseases, 942; in laryngeal tuberculosis, 1027; in local tuberculosis, 221; mercury, 1134.
Pyosepticemia, 63.
Pyramidal fibers, homolateral, 1179.
Pyramids of the medulla, 1152.
Pyrantin, 1135.
Pyrogallic acid in onychomycosis, 1085.
Pyrozone in vulvitis, 554.

Quadriceps extensor femoris, rupture of the tendon of, 354.
Quadrigeminal body, gliosarcoma of, 993.
Quarter-diopter cylinder, 897.
Queirel on the pubic symphysis, 536.
Quénu on anterior kolpotomy, 647; on carcinoma of the stomach, 269.
Querken on the hip-joint, 881.
Quervain on typhoid fever, 24.
Quesnier on rupture of the uterus, 525.
Quincke on pulmonary abscess, 115; and Hochhaus on anemia, 94; puncture, 792, 855, 989; theory, 549.
Quine on Addison's disease, 106; on typhoid fever, 29.
Quinin in African fever, 57; amblyopia, 930; in anemia, 95; in black-water fever, 55; in chyluria, 198; in diabetes mellitus, 86; in eczema, 1033; -eruption, 1052; in glaucoma, 923; in herpes pudendalis, 555; in influenza, 52; and infusoria, 1135; in Ménière's disease, 969; -poisoning, 1137; in pregnancy, 485; in surgical tuberculosis, 222.
Quintuplets, 530.

Rabczewsky on puerperal eclampsia, 515.
Rabies, 61.
Rabinowitsch on pathogenic yeasts, 725.
Rachford on intestinal digestion, 1176; on lithemia, 78, 79; on tuberculosis, 44.
Rachitic children, sense of taste in, 778; curves, spontaneous cure, 889; pelves, 514.
Rachitis, etiology, 777; theory of scurvy, 779.
Radasewzky on myocarditis, 134.
Radical cure of hernia, 284.
Radiographs, 199.
Radzveitzky on glaucoma, 922.
Railroad signals, acoustic, 970.
Railton on cardiac anomalies, 787.
Railway-sickness, sulfonal in, 1142.
Rackowicz on the optic tracts, 930.
Ramm on appendicitis, 170.
Ramsay on abdominal section, 308.
Ramsden on fracture of the hyoid, 1019.
Ramsey on glaucoma, 923; on lacrimal obstruction, 909.
Ramus maximus nervi facialis, 1153.
Randall (B. A.) on cholesteatoma of the ear, 978; on co-

nus, 924; on labyrinthine deafness, 971; on massage of the middle ear, 972.
Randolph on keratitis, 939.
Ranney on epilepsy, 816; on the eye in epilepsy, 946.
Ransom on acromegaly, 844; on nævus unius lateris, 1063.
Raoult on foreign bodies in the ear, 959.
Rapin on the iliofemoral pelvis, 514.
Rasch on papillomata of the buccal mucosa, 1012.
Rash in typhoid fever, 20, 26.
Rauge on paralysis of the eye-muscles, 901; on purulent otitis media, 974.
Ravenel on membranous rhinitis, 1000.
Raw on opium-poisoning, 1134.
Raymond on crossed hemiplegia, 836; on the eye in measles, 951; on phlegmasia alba dolens, 542.
Raynaud's disease in children, 795, 832.
Rays, Röntgen, 420.
Reach's test, 1190.
Reale on lavage of the stomach, 163.
Reber on blepharospasm, 945; on the eye in epilepsy, 946.
Recinck on mammary abscess, 215.
Reclus on cocain-poisoning, 235; on crushes of the limbs, 418; on surgery of the lung, 329.
Rectal examination in labor and pregnancy, 505; mucus in tuberculosis, 43.
Rectovaginal fistula, 572.
Rectum, carcinoma of, 325, 563; diseases of, 325; excision of 326; lymphatics of, 1148; syphilitic stricture of, 327.
Rectus, superior, paralysis of, 900.
Recurrence after carcinoma, 257.
Recurrent osteomyelitis, 370; ocular palsies, 905; scarlatinoid erythema, 1032.
Recurring chancres, 381.
Red blood-corpuscle, 1184; formation of, 1162; genesis of, 675; oxid of mercury in anal pruritus, 327; phlebotomy, 858.
Red (S. C.) on puerperal eclampsia, 515.
Redlich on multiple sclerosis. 685.
Redner on cholesteatoma of the ear, 978.
Reduction of dislocation of the hip, 879, 880.
Reed on typhoid fever, 719.
Reflex action, 1179; epilepsy, 815; neuroses, 819; symptoms in ametropia, 893.
Refraction, 897; use of atropin in, 900.
Regaud on the spinal cord, 861.
Regeneration of lymphatic vessels, 1149; of nerve-cells, 1180.
Regenerative tension, 707.
Regis on general paralysis, 869.
Regurgitation, aortic, 132; mitral, 131.
Rehn on carcinoma of the rectum, 563; on stone in the gall-bladder, 320; -Rydygier operation, 636.
Reibmayer and Höffinger on absorption, 1166.
Reiche on the kidneys in diphtheria, 755.
Reichel on peristalsis, 657.
Reichmann on sodium bicarbonate, 1139.
Reid (W.) on ear-vertigo, 970; on gunshot wounds, 444; on the Röntgen rays, 423.
Reifsnyder on abdominal section, 650.
Reilly on ringworm, 1048.
Reimer and Frisch on anemia, 95.
Rein on cardiac paralysis, 249; on hermaphroditism, 564.
Reiner on amblyopia, 932.
Reinert on iron, 1125; on anemia, 93.
Reinfection, syphilitic, 1098.
Reinhard on acute otitis media, 966.
Reinhold on thyroid-feeding in insanity, 870.
Reinicke on asepsis in labor, 505; on nephritis, 193; on trional, 1144; on the larynx, 1156.
Reismann on secondary abdominal pregnancy, 498.
Reiss on optic neuritis, 933.
Relapses in pneumonia, 113; in scarlatina, 767.
Relapsing appendicitis, 290.
Remittent fever, 54.
Remlinger on Landry's paralysis, 687.
Removal of the Gasserian ganglion for neuralgia, 384; of plaster-of-Paris bandages, 203; of the stapes, 981; of the uterus and appendages by continuous incision, 619.
Remy on maternal death during labor, 528.
Renal calculi, 185; calculus in women, 410, 582; deposits of uric acid, 1144; diabetes, 82; disease and cardiovascular changes, 147; diagnosis of, 581; function and glycosuria, 82; insufficiency in cystic disease of the chorion, 462; neuralgia, 415; tuberculosis, 194; tumors, 195.
Rendu on uremic aphasia, 193; on uterine prolapse, 605.
Renon on aspergillosis of the lungs, 698; on pseudotuberculosis, 115.
Renoy's treatment of erysipelas, 51.
Renton (C.) on tuberculous peritonitis, 375.
Rentoul on obstetric education, 450.
Repeated extrauterine pregnancy, 497.
Resection for empyema, 333; for intestinal perforation, 301; of Meckel's ganglion for neuralgia, 384.
Resinelli on deciduoma malignum, 463.
Resnikow on missed labor, 481.
Resonance, vocal, 107.
Resorcin in acne, 1083; in eczema, 1035; in hay fever, 1002; in pityriasis rubra pilaris, 1079; in summer diarrhea, 784.
Resorption-infection, 742.
Respiration, 1177; artificial, 250; in the newborn, 547.
Respiratory mucosa in bronchitis, 670; organs, diseases of, 327, 696.
Rest in surgical tuberculosis, 223.
Rests, suprarenal, 196; kidney-tumors derived from, 701.
Retained placenta after abortion, 488.
Retention-theory of glaucoma, 922; of urine in children, 796; of urine in a fetus, 533.
Rethi on the brain, 1180; on ozena, 1000.
Retina, 1182; anatomy of, 925; central artery of, 1155; detachment of, 928; diseases of, 925; glioma of, 929; physiology of, 925; rods and cones of, 1155; sarcoma of, 929; tumors of, 929.
Retinal hemorrhage, 926; tire and hysteria, 925.
Retinitis, albuminuric, 926; of pregnancy, 944; diabetic, 928; pigmentosa, 927; syphilitic, 928.
Retinoscopy, 895, 955.
Retraction in carcinoma of the heart, 261.
Retrobuccal method in neuralgia, 384.
Retrocession of the uterus, 606.
Retrodisplacement of the uterus, 606.
Retroflexion of the uterus, 607.
Retropharyngeal abscess, 788, 1017.
Retroposed uteri, adherent, 608,
Retroposition of the uterus, 606.
Retrorectal dermoid cysts, 663.
Retroversion uteri in pregnancy, 475.
Reusing on rupture of the uterus, 525.
Revaccination, 49.
Reverdin and Buscorlet on uterine tuberculosis, 599; and Benckisser's method, 208.
Revision of the uterus after labor, 507.
Rey on the absorption of lime-salts, 778.
Reynier on fractures, 358.
Reynolds on gonorrheal conjunctivitis, 914; on cystoscopy, 577; on extrauterine pregnancy, 502; on spontaneous rupture of the uterus, 478.
Reynolds (J. R.) on exophthal-

mic goiter, 864; on rheumatoid arthritis, 76.
Rhenier on exophthalmic goiter, 143.
Rheostat, 998.
Rheumatic diathesis in acute tonsillitis, 1014; endocarditis, 126; fever, 71.
Rheumatism, 69; and appendicitis, 170; and chorea, 71; and dermatomyositis, 74; and endocarditis, 70, 125; and erythema nodosum, 71, 72; gonorrheal, 74; gonorrheal, in the puerperium, 540; guaiacum in, 1122; microorganisms in, 72; salicyl compounds in, 73; salophen in, 73; serumtherapy in, 74; symptoms, 73; temperature in, 71; and tonsillitis, 71–73; treatment, 73; urine in, 70.
Rheumatoid arthritis, 76.
Rhigolene, 239.
Rhinalgin in dacryocystitis, 909.
Rhinitis, 999; argentamin in, 1109; dry treatment, 999; hypersecretoria, nosophen in, 1127; hypertrophic, 999; membranous, etiology, 1000; tannigen in, 1143.
Rhinology, surgery in, 997.
Rhinophyma, 1007.
Rhinoplasty, 1008.
Rhinoscleroma, 1078.
Rhus aromatica in nocturnal incontinence, 831.
Rib, cervical, 338; breaking-strain of, in the sane and insane, 864.
Ribbert on carcinoma, 629; on carcinoma of the lungs, 120; on tumors, 706.
Ricard on suture of veins, 342, 343.
Rice on disease of the larynx, 1026; on ulceration of the nasal septum, 1007.
Richard on curettage, 603.
Richardson on anemia, 95; on appendicitis, 289.
Richardson (B. W.) on diagnostic auscultation of joints, 377; on the ether spray, 239; on larvæ in the ear, 959; on lithotomy, 404; on ovarian dermoid, 663; on sugar as a dressing, 217; on suture of the gall-ducts, 319.
Richelot on ureterovaginal fistula, 573; on vaginal hysterectomy, 636.
Richer (A. J.) on catgut, 209.
Richey on intratympanic surgery, 972.
Richter on acute yellow atrophy of the liver, 179.
Ricker on placental transmission, 457; on uterine fibroids, 617.
Rickets, 777.
Ricketts on lupus vulgaris, 1073.
Ridges, papillary, of fingers and toes, 1158.
Ridlon on club-foot, 886; on iodoform-injections, 879.
Riedel on chronic pancreatitis, 184.
Rieder on cardiac hypertrophy, 133; on diagnosis of new growths by microscopic examination of transudates, 740.
Riehl on psoriasis vulgaris, 1036.
Rieken on lumbar puncture, 855.
Ries on igniextirpation of the uterus, 638.
Riesman (D.) on paulocardia, 139; on xerostoma, 1012.
Rifles and projectiles, 436; -wounds, 443.
Rigidity, cervical and vulvar, 519, 520.
Rilliet and Barthez on measles, 764, 765.
Ring (G. O.) on sympathetic ophthalmia, 920; on tumor of the optic nerve, 935.
Ringer (S.) on diabetes mellitus, 87; and Phear on Addison's disease, 104.
Ringworm, 1047.
Rininger on suppression of urine, 185.
Rioblanc on Gritti's amputation, 229.
Risley (S. W.) on discission of the capsule, 954; on foreign bodies in the eye, 952; on glaucoma, 923; and Thorington on abnormalities of the orbits, 895.
Ritschl on amputation of the leg, 229.
Ritter on uric-acid deposits, 1189; on uricedin, 1145.
Ritter's disease, 549, 1043.
Rivers, cleansing and pollution of, 1185.
Rixford and Gilchrist on protozoan infection of the skin, 1076.
Rizzoli's operation, 568.
Robb on carcinoma uteri, 631.
Robert on puerperal eclampsia, 514.
Roberts on anarcotin, 1102; on phosphaturia, 185; on quinin-poisoning, 1137; on trichophytosis, 1048; on the urine, 1193.
Roberts (J. B.) on congenital dislocation of the head of the humerus, 373; on malignant tumors treated by erysipelas-toxins, 253; on phlegmasia alba dolens, 541; on transperitoneal ureterolithotomy, 412.
Robertson on carcinoma of the iris, 920; on gastritis, 160; on purulent otitis media, 974; on salivary digestion, 156; on the sphygmograph, 123.
Robin on diabetes mellitus, 86.
Robinson on cough, 107; on variola, 46.
Robinson (B.) on appendicitis, 170, 292; on peritoneal adhesions, 173, 655; on subluxation of the knee-joint, 375; on syphilitic joint-diseases, 381, 776; on urethritis, 379.
Robinson (F. B.) on abdominal section, 651.
Robison on leukemia, 101; on tuberculosis, 41.
Robitschek on peptonuria, 1192.
Robson (M.) on contracted bladder, 402, 579; on enormous hernia, 283; on meningocele, 386; on spina bifida, 382.
Robson (A. W. M.) on pyloroplasty, 268.
Rocci on iron, 1126.
Rochester on the blood, 94.
Rochon-Duvignaud on choroiditis, 924; on papillitis, 933.
Rods and cones of the retina, 1155.
Roe on damp air, 998.
Roeber on cyst of the thyroid, 351.
Röntgen rays, 199, 420, 1182; in anatomy, 1147; in arteriosclerosis, 199; and bacteria, 422; in obstetrics, 458; in ophthalmology, 953, 954; and osteology, 428; and spinal caries, 425.
Röpke on acute otitis media, 965.
Roesch on hysteric pseudomeningitis, 806; on tuberculous peritonitis, 277.
Roesing on endometritis, 601.
Roessler on achillodynia, 888.
Roeth on diphtheria, 758.
Roger on erysipelas, 49; on infantile paralysis, 794; and Josué on appendicitis, 170.
Rogers on enterectomy, 298; on guaiacol, 1121.
Rogman on carcinoma of the limbus, 917; on conjunctival cysts, 916; on corneal ulcer, 940; on sympathetic ophthalmia, 921.
Rohmer on cataract, 937; on the eye, 934; on foreign bodies in the eye, 952; on tumor of the orbit, 912.
Rolland on antipyonin, 943; on vaginitis, 556.
Rolleston on acromegaly, 844; and Hayward on dilatation of the colon, 169.
Roman method of treating malaria, 485.
Romberg on infectious fevers, 138.
Rombolotti on conjunctival cysts, 916.
Romine on constipation, 168.
Romme on cardiac hypertrophy, 787; on puerperal sepsis, 540.
Rommelaere's sign, 185.
Roncali on blastomycetes, 708.
Rook on acetanilid-poisoning, 1101.
Roos on thyreoiodin, 1104, 1169.
Roosing on carcinoma of the kidney, 414.
Rosacea hypertrophica, 1007.
Rose on hernia, 282.
Rose's operation, 384.

Rosenbach on insomnia, 832.
Rosenbaum on the epiglottis, 1020.
Rosenberg on fibroid tumor of the uterus in pregnancy, 480; on occipitoposterior position, 528; on valvular cardiac disease in pregnancy, 469.
Rosenberg's method, 245.
Rosenfeld on the urine, 187; on vesical calculus in pregnancy, 480.
Rosenheim on the esophagoscope, 152; on eudoxin, 1128; on the gastroscope, 156.
Rosenmeyer on foreign bodies in the eye, 952.
Rosenthal (W.) on iron, 1125; on mercurial eruptions, 1052; on respiration, 1177; on tetanus neonatorum, 753.
Rosenwasser on extrauterine pregnancy, 495.
Rosner on intestinal obstruction, 655.
Ross (J. F. W.) on extrauterine pregnancy, 495; on malarial fever, 53; on pneumoperitoneum, 660; on repeated extrauterine pregnancy, 497; on statistics of labor, 502.
Rossner on the ovaries in osteomalacia, 666.
Rosthorn on carcinoma uteri, 630.
Rotation inward in club-foot, 885.
Rotch and Wentworth on meningitis, 793.
Roth on cerebrospinal meningitis, 836.
Rouis on hepatic abscess, 315.
Round ligament, adenomyoma of, 664; ulcer of the stomach, 266; worms, 786.
Roure on myopia, 898.
Rousseaux on benign tumors of the larynx, 1024.
Routier on hypertrophy of the prostate, 407.
Roux on antitoxin, 764; on the semilunar cartilages, 377; on the treatment of hemorrhoids, 326; on tetanus, 840.
Roux's method, 558.
Row on Cesarean section, 536.
Roy on nasal polypi, 1004.
Rubeska on dermoid cyst in pregnancy, 479; on puerperal tetanus, 541.
Rudaux on empyema of the antrum, 1008.
Rudimentary ovarial parasites, 706.
Rudolph on erysipelas in syphilis, 1096.
Rue, goat's, 1120.
Rüdel on uric acid, 1145.
Rühl on dystocia after vaginofixation, 525.
Ruge on malignant adenoma of the uterus, 630; on pneumonia, 113.
Ruhrah on intussusception, 785.
Rumpf on ammoniuria, 700; on Zuckergussleber, 694.
Runge on deciduoma malignum, 464.
Rupia-like eruption of potassium iodid, 1051.
Rupp on fat-milk, 747.
Rupture of the biceps, 355; of brain-abscess, 993; of the chorcid, 925; in extrauterine pregnancy, 491, 494; of the eye, 953; of the heart, 145; intraperitoneal, of the bladder, 400; of the iris, 920; of the liver, 315; of the pancreas, 311; premature, of the membranes, 461; spontaneous, of the mastoid cells, 980; spontaneous, of the uterus, 477; spontaneous, of the umbilical cord, 461; of the tendon of the quadriceps extensor femoris, 354; of the urethra, 398; of the uterus, 525.
Russel on Laborde's method, 547.
Russell on carcinoma uteri, 637.
Ruth on bullet-wounds of the skull, 447; on fibromyoma in pregnancy, 481.
Ruthen on syphilis of the ear, 971.
Rydygier on actinomycosis, 1055; on exophthalmic goiter, 352; on intestinal invagination, 309; on splenopexy, 314.
Rydygier's method, 208.

Saalfeld on skin-diseases, 1087.
Sabanejeff's amputation, 228.
Saboraud on onychomycosis, 1086.
Sabrazes on goiter, 150.
Sac, lacrimal, actinomycosis of, 910.
Saccharomyces ellipsoideus neoformans, 708, 711; litogenes, 710.
Sacculated kidney, 414.
Sachs on idiocy, 867.
Sachsalber on the optic nerve, 930; on ulcus cornea serpens, 940.
Saddle, bicycle, 584, 585.
Sänger on accessory ostium tubæ, 537; on drainage, 653; on prolapse of the ovary, 665; on rupture of the uterus, 525; on sponges, 212; operation, 536.
Safety of anesthetics, 244.
Sainz on senile bronchitis, 109.
Salicin in psoriasis, 1036.
Salicyl compounds in rheumatism, 73.
Salicylates in acute endocarditis, 126; in psoriasis, 1036.
Salicylic acid, 1137; as an antiseptic, 944; in eczema, 1034; in rheumatism, 74; in tuberculosis, 39; in vulvitis, 554.
Saline enemata in hemorrhage, 344; solutions in diarrhea, 169; Szumann's, 432.
Salipyrin in metrorrhagia, 589.
Salivary calculus, 1012; digestion, 156; glands, diseases of, 350.
Salkowski on nutrose, 1130.
Salol in epilepsy, 815; in gonorrhea during pregnancy, 474; in lithemia, 79; local action, 210; in nephritis, 194.
Salophen in rheumatism, 73.
Salpingitis, gonorrheal, 474, 557.
Salt in diabetes mellitus, 87; Seignette, in diabetes mellitus, 86.
Salvati and Gaetano on carcinoma, 735.
Salvioni on Röntgen rays, 1147.
Salzer on the stomach, 152.
Samfirescou's amputation, 226.
Samguine on cardiac ulcer, 146.
Sanderson (B.) on malignant disease of the heart, 259; on reflex action, 1179.
Sane, breaking-strain of the ribs in, 864.
Sanfelice on pathogenic yeasts, 725; on saccharomyces ellipsoideus neoformans, 708.
Sanitary nursing-bottle, 745.
Sanoform, 1137.
Sarbo on tetany, 839.
Sarcoma of the bladder in children, 800; blastomycetes in, 708; of the brain, 689; in childhood, 781; of the choroid, 924; chorion-cell, 488; deciduocellulare, 623; of the ear, 958, 976; of the femur, 265; of the kidney in children, 799; of the lacrimal gland, 909; mastoid, 981; nasal, 1005; and nasal polypi, 1004; of the orbit, 911, 912; of the pancreas, 696; of the peridontal membrane, 690; of the retina, 929; of the uterus, 623; of the vagina in children, 800.
Sarcomatous degeneration of a uterine fibroid, 617.
Sattler on myopia, 898.
Saturnine gout, 80.
Saturnism, chronic, 80.
Saul on sterilization of catgut, 207.
Saundby on cardiac disease, 135; on multiple neuritis, 829.
Saunders on diphtheria, 764.
Sauvineau on paralysis of the eye-muscle, 900.
Savage on advancement, 903.
Savill on itching, 1059; on perioral eczema, 1033.
Savoire on carcinoma, 185.
Sawford on ophthalmia nodosa, 917.
Sawhill (W. F.) on puerperal tetanus, 541.
Sawyer on statistics of labor, 503; on tuberculosis, 43.
Sayre on club-foot, 886.
Scabies, balsam of Peru in, 1049.
Scadding on puerperal eclampsia, 514.
Scarlatina, 765; blood in, 768; contagion in, 766; eucalyptus

oil in, 769; gangrene after, 766; ichthyol in, 769; Marmorek's antistreptococcic serum in, 767; relapses in, 767; secondary rashes in, 767; streptococci in, 768; suppurative joint-lesions of, 376; temperature in, 769; trional in, 802.
Scarlatinal arthritis, 769.
Scarlatinoid erythema, recurrent, 1032.
Scarlet fever, 765.
Scattleff on massage of the middle ear, 972.
Schadewald on laryngeal tuberculosis, 1026.
Schadle on adenoid hypertrophy, 1010.
Schaeffer on metrorrhagia, 590; on perityphlitis in children, 785; on tabic amyotrophy, 686; and Moore on vasomotors, 1167.
Schamberg on impetigo contagiosa, 1037.
Schaper on glandulæ parathyroideæ, 1160.
Schapps on Pott's disease, 876.
Schapringer's theory, 911.
Schardinger on amebæ, 738.
Schatz on contracted pelvis, 512.
Schauta on vesicovaginal fistula, 572.
Schavoir on typhoid fever, 19.
Schede on carcinoma of the rectum, 326.
Schede's method, 339.
Scheff on laryngeal fracture, 1022.
Scheffer on sarcoma of the lacrimal gland, 909.
Scheibe on fibroma of the ear, 960.
Schell on diphtheria, 762.
Schenck on muscular energy, 1171, 1172; and Fuss on sight, 1182.
Scheppegrell on bipolar electrolysis, 999; on cautery-irons, 997; on hemorrhage from the antrum, 1009; on infection of the ear, 960; on vertigo, 1011.
Schetelig's method, 1122.
Schietzler on intestinal obstruction, 109.
Schild on intestinal bacteria in the newborn, 750.
Schimmelbusch on multiple primary carcinoma, 704.
Schirman on anosmia, 1003; on tetanus neonatorum, 753.
Schistocytes, 672.
Schleich on eucain, 234, 1118.
Schleich's method of anesthesia, 200, 235.
Schlesinger on diphtheria, 756; on obesity, 88.
Schloffer on hernial fluid, 278.
Schlossmann on perityphlitis in children, 785,
Schmal on uterine fibroid, 616.
Schmeichler on choroiditis, 924.
Schmid on vaginal hysterectomy, 637.
Schmidt on protozoa in the lungs, 116, 743; on puerperal insanity, 472; on sclerema neonatorum, 549, 752; Rempler on foreign bodies in the eye, 952; on retinal tire, 925; on subconjunctival injections, 942.
Schmiegelow on otitic cerebral complications, 987.
Schmorl and Kockel on placental tuberculosis, 460.
Schnabel and Herrnheiser on myopia, 897.
Schnee on coryza, 1001.
Schnesinger on loretin, 210.
Schöndorff on urea, 1173.
Schönfeld on typhoid fever, 29.
Schönheimer on malignant adenoma of the uterus, 630.
Scholz on Graves' disease, 143, 1019.
Schoolfield on placental inflammation, 459.
Schott on gouty affections of the heart, 139; method, 123, 135, 143.
Schramm on pelvic hematoma, 656.
Schreiber on icterus neonatorum, 549, 752; on puerperal eclampsia, 514.
Schrenck on extrauterine pregnancy, 496.
Schroeder on actinomycosis of the lacrimal sac, 910; on dysmenorrhea, 590; on malignant adenoma of the uterus, 630; on traumatism of the kidney, 413.
Schronck on stammering, 1029.
Schuchart on salicylic acid, 1137.
Schülzke on topography of the skull, 979.
Schürmayer on protozoa in the intestines, 743.
Schule on digestion, 162; on gastric juice, 1175.
Schultze on birth-palsies, 823; on lumbar puncture, 858; on lupus vulgaris, 1072; on ovarian dermoid, 663.
Schumburg and Zuntz on respiration, 1177.
Schuster on carbon-dioxid, 1112.
Schwartz on abdominal section, 649; on Cesarean section, 536.
Schwartze on brain-tumor, 993; on excision of the ossicles, 978.
Schwartze's operation, 965.
Schwarz on carcinoma, 707; on extrauterine pregnancy, 494.
Schwarzchild on orbital cellulitis, 910.
Schweigger on glaucoma, 923.
Schweiger on antipyrin in diphtheria, 764; on hepatic abscess, 179.
Schwerdt on enteroptosis, 158; on intraabdominal pressure, 159.
Schwinn (J.) on injury of the thoracic duct, 348.
Sciatica, 818, 819; nitroglycerin in, 1128.
Sclavo on antianthrax serum, 734.
Sclera, diseases of, 917.
Sclerema of the conjunctiva palpebra, 917; neonatorum, 549, 752.
Scleroderma, diffuse, 1063; ichthyosis simulating, 1060.
Sclerosis, disseminated, 685; disseminated, eye in, 947; of the ear, 971; multiple, 685; spinal, in children, 794.
Sclerotomy in glaucoma, 923.
Scofone and Battistini on anesthetics, 233.
Scopolamin, 1109; in cycloplegia, 900.
Scorbutus, eye in, 951; from sterilized milk, 548.
Scotoma, annular, 928.
Scott on ophthalmia neonatorum, 914.
Screw-worm in the ear, 959.
Scrofula, skin-diseases in, 1073.
Scrofuloderma, 1074.
Scrofulous pustuloderma, 1074.
Scrotum, angiokeratoma of, 1064.
Scurvy, 106; in children, 779; rachitis-theory, 779.
Seabrook on the eye in liver-disease, 951.
Seagrave on neuralgia, 818.
Sears on acromegaly, 846.
Sea-sickness, sulfonal in, 1142.
Seborrhea, vaginal, 556.
Seborrheic vaginitis, 556.
Secondary abdominal pregnancy, 498; cataract, 937; infection after acute otitis media, 965; parotitis and gastric ulcer, 166; rashes in scarlatina, 767.
Secretion, internal, 1168; vaginal, in the newborn, 548.
Section, abdominal, 649; hernia after, 278; Cesarean, 536; postmortem, 528; frozen, in labor, 508; perineal, 397.
Sée on lupus erythematosus, 1070.
Seegen on muscular energy, 1172.
Seelig on leukemia, 101.
Seggel on subconjunctival injections, 942.
Ségond on rectovaginal fistula, 572; on sepsis, 218.
Ségond's operation, 649.
Segual on amblyopia, 900; on cataract, 936.
Seguen on ovarian cyst, 660.
Seguin on accommodation, 899.
Seibert on diphtheria, 764; on ichthyol in scarlatina, 769; on the nursing-bottle, 746; and Schwyzer on antitoxin, 763.
Seifert on empyema of the antrum, 1008; on nasal syphilis, 1006; on nosophen, 1127; on tracheal stenosis, 110.
Seignette salt in diabetes mellitus, 86.
Seiler (C.) on perforation of the nasal septum, 1007.
Selbach on anesthetics, 246.

Sellman on metritis, 595.
Selva on bandaging the thumb, 204; on malignant tumors, 254.
Semb on uterine fibroid, 616.
Semilunar cartilages, traumatic inflammation of, 377.
Seminal vesicles, diseases of, 406.
Semple on typhoid fever, 26.
Semtschenko on varicella, 772.
Senator on diabetes mellitus, 84; on renal tuberculosis, 195.
Sendziak on angioma of the nasal septum, 1005.
Senega-root, 1138.
Senile bronchitis, 109; changes in the middle ear, 969; deafness, 969; stricture of the urethra, 576.
Senn (N.) on appendicitis. 289; on drainage, 652; on malignant tumors, 254; on military surgery, 429; on pancreatic rupture, 311.
Sensation of temperature, 1182.
Sense, special, organs of, 1154; of taste in rachitic children, 778.
Sensory dissociation in peripheral disease, 831; paralysis, elective, 831.
Sepsis and pregnancy, 474; puerperal, 538; serum-treatment of, 218.
Septic infection and shock, 218; peritonitis, 277; throat-inflammation, 1013.
Septicemia, 62; from acute otitis media, 965; anthrax, 126; gonorrheal, 62; from mammary abscess, 215; tetragenus, 714.
Septicopyæmia, 62; typhosa, 719.
Septum, nasal, papilloma of, 1004; patent ventricular, 144; transverse vaginal, 565.
Serenine on lupus vulgaris, 1073.
Serous spaces, absorption from, 1166.
Serum, antianthrax, 734; antistaphylococcic, 734; antistreptococcic, 50, 519, 734; antitubercle, 40; Hayem's, 218; Maragliano's, 41; Marmorek's, 17.
Serum-therapy in carcinoma, 735; in diphtheria, 672, 758; in diphtheric conjunctivitis, 914; in fever, 69; in malignant growths, 254; in puerperal sepsis, 218, 220, 542; in rheumatism, 74; for syphilis, 1094; in tuberculosis, 40, 731; in typhoid fever, 28, 733; in variola, 48.
Sesamum, oil of, 1138.
Setter on malformations of the auricle, 958.
Sewer-rat, experimental Addison's disease in, 704.
Sex, procreation of, at will, 452.
Sexton on postclimacteric endometritis, 601.
Sextuplets, 530.
Shadow-test, 954.
Shaffer on cold abscesses, 877; on slipping patella, 883.
Shands on compression-myelitis, 876.
Sharkey on multiple neuritis, 829.
Sharp on albumin, 1192; on the atropin-group, 1109; on the cocain-habit, 997; on malpractice, 1183; on poisoning by opium, 1133.
Sharpless on arrhythmia, 139.
Shattuck on exophthalmic goiter, 141; on peritonitis, 174; on tuberculosis, 44.
Shaw on placenta prævia, 483; -Mackenzie on sulfonal, 1142.
Shearer on dystocia, 521.
Shede on the hip, 880.
Sheep's serum in lupus erythematosus, 1072.
Sheibe on cholesteatoma of the ear, 978.
Sheild on carcinoma of the heart, 260; on lupus vulgaris, 1072; on mammary abscess, 213; on mastoid disease, 391.
Shepard (F. J.) on carcinoma, 628.
Shepherd on bronchocele, 351; on purpura, 1058.
Sheppard on hysteric mastoiditis, 981.
Sherman on tuberculous osteomyelitis, 878.
Sherrington on mammary abscess, 214.
Shick on obstetric forceps, 534.
Shield on chronic otorrhea, 979.
Shields on the plethysmograph, 1167; on typhoid fever, 29.
Shillitoe on indurated pseudochancres, 380.
Shock, 433; acute nephritis from, 798; Esmarch bandage in, 344; and septic infection, 218.
Shoemaker (G. E.) on uterus cordiformis, 595.
Short on renal tumors, 195.
Shoulder-brace, 875; -joint, luxatio erecta of, 374.
Shoulders, fetal, impaction of, 532; presentation of, 532.
Shropshire on tuberculosis, 41.
Sibley on Addison's disease, 104.
Sicher (V.) on subconjunctival injections, 942.
Sicherer on ophthalmia neonatorum, 914.
Siebenman on rhinitis, 999.
Siegel on foot-and-mouth disease, 714.
Siegrist on retinal hemorrhage, 926.
Sight, 1182.
Sigmund on syphilis, 1098.
Sign, first rib, 121.
Signe du cordeaux, 119.
Signs of maturity at birth, 546.
Signier on pregnancy and exophthalmic goiter, 470.
Silex on albuminuric retinitis, 944; on congenital syphilis, 1090; on entropion, 907; on exophthalmic goiter, 142; on the iris, 918.
Silk on anesthesia, 996.
Silk-infection after hysterectomy, 622.
Silver citrate, 1138.
Silver lactate, 1138.
Silver nitrate in corneal ulcer, 940; in cystitis, 577; in gonorrheal urethritis, 556; in gonorrheal vaginitis, 557; in gonorrheal vulvitis, 556; in nasal catarrh, 787; in ophthalmia neonatorum, 549; in summer diarrhea, 784.
Simes on the kidney, 1188.
Simi on hypopyon, 941; on glaucoma, 622, 923; on retinal detachment, 928; on sympathetic ophthalmia, 921.
Simmonde on pedatrophy, 700.
Simmons on analgesia in labor, 507.
Simon on adenoids in children, 1011; on epithelioma of the larynx, 1026; on glaucoma, 922; on indican in the gastric juice, 154; on lupus of the larynx, 1025; on septic throat-inflammation, 1013; on typhoid fever, 26, 28.
Simple continued fever, 18, 65; endometritis, 597.
Simpson on nasal surgery, 997; on typhoid fever, 24.
Sims on sarcoma of the bladder, 800.
Simulo in epilepsy, 814.
Sinclair on the eye, 901; on uterine carcinoma, 632.
Singer on rheumatism, 70; on the thyroid gland, 1018; on typhoid-bacilli, 719.
Singultus fœtalis, 464.
Sinkler (W.) on complete division of the musculospiral nerve, 383; on neuralgia, 818.
Sinus, frontal, empyema of, 910; lateral, involuntary opening of, 981; -phlebitis, otitic, 990.
Sinusitis, 1009.
Sior (L.) on peptonuria, 1190.
Siphonage of the bladder, 399.
Sivitalski on metrorrhagia, 588.
Size, excessive, of the fetus, 531.
Sjöqvist on dietetics, 1174.
Skene (A. J. C.) on neurasthenia in women, 551; on ovarian cyst, 664; on patency of Gärtner's duct, 563.
Skene (W. H.) on inversion of the uterus, 526.
Skiagraphy, Röntgen, 199.
Skiascope, 420.
Skin, action of phenol on, 1043; anatomy of, 1158; coccidioidal infection of, 1076; diphtheria of, 1047; hemorrhage from, 1057; medullated nerves of, 1158; neuroses of, 1059; pigment-anomalies of, pathology of, 1062; protozoan infection of, 1076; tuberculosis of, 1073; tumors of, 1063.
Skin-bridging in inguinal colotomy, 310.

Skin-diseases in Bright's disease, 1049; and diet, 1086; and erysipelas, 1047; follicular, 1078; glandular, 1078; from iodin-liniment, 1053; and nephritis, 192; in the newborn, 549; pernicious, 1046; potassium permanganate in, 1087; in scrofula, 1073.
Skin-grafting. 419; in mastoid disease, 391.
Skin-lesions of syringomyelia, 1056.
Skull, base of, fracture of, 934; bullet-wounds of, 446; and ear, topography of, 979; fracture of, 390.
Slaughter on amebic abscess of the liver, 315; on piperazin, 1133.
Sleep, chloroformization during, 243; and digestion, 162.
Sleicher on the rheostat, 998.
Slipping patella, 883.
Slocum (H. A.) on Cesarean section, 536.
Sloughing of fibroid tumors after labor, 521.
Slow anesthesia, 241.
Smallpox, 45; in pregnancy, 473.
Smirnow on diphtheria, 733, 759.
Smith (A. H.) on the differential stethoscope, 123; on guaiacol, 1122; on pernicious anemia, 99; on urine analysis, 1190.
Smith (Alfred J.) on myosarcoma of the ovary, 664; on tubal pregnancy, 493.
Smith (E.) on adenoids in children, 1011; on hay fever, 1002.
Smith (G.) on abdominal tumor, 275; on hydrocele in the woman, 564; on perforation in typhoid fever, 294; on postoperative intestinal obstruction, 303; on relapsing appendicitis, 290.
Smith (J. L.) on cerebrospinal meningitis, 837; on pneumonia, 111; on tetanus neonatorum, 753, 841; and Sturge on scarlet fever, 376.
Smith (M.) on acute otitis media, 967; on excision of the ossicles, 976; on sarcoma of the peridental membrane, 690.
Smith (P.) on nephritis, 192; on optic atrophy, 934; on the Röntgen rays, 425.
Smith (T.) on the colon-bacillus, 721; on diphtheria, 759.
Smith (T. C.) on cervical dystocia, 519; on ventrofixation, 615.
Smith (W. G.) on skin-diseases, 1086.
Snegirjoff on steam as a hemostatic, 588.
Snell (S.) on albuminuric retinitis, 944; on chancre of the eyelid, 906; on infection of the orbit, 910; on lacrimal obstruction, 910; on syphilis of the conjunctiva, 917.
Snow (H.) on cystic degeneration of the mammæ, 265; on loretin, 210; on pseudomembranous enteritis in children, 786; on scurvy, 779; on summer diarrhea, 783.
Soap-solution, disinfecting power of, 1186.
Sobieránski on muscular energy, 1172; on the urine, 1174.
Sobotka on vaccina, 48.
Soca on glandular fever, 777.
Socin on cyst of the thyroid, 351.
Sodium arseniate in diabetes mellitus, 86.
Sodium benzoate in gonorrheal cystitis, 556.
Sodium biborate in glaucoma, 923.
Sodium bicarbonate in diabetes mellitus, 86; and the gastric secretion, 1139; in vaginitis, 556.
Sodium bromid in tetanus neonatorum, 753.
Sodium chlorid in metabolism, 1112; in nasal pain, 1003; in ringworm, 1048.
Sodium fluorid, 211.
Sodium glycerophosphate in exophthalmic goiter, 143, 837.
Sodium iodid in acute endocarditis, 126.
Sodium phosphate in Graves' disease, 1019.
Sodium salicylate in appendicitis, 170; in epilepsy, 815; in glaucoma, 923; in gonorrhea during pregnancy, 474; in lithemia, 78, 1137; purpuric eruption after, 1058; and uric acid, 1137.
Sodium salts in the uric-acid diathesis, 186.
Sodium sulphoricinate in pharyngitis, 1017.
Soft palate, tuberculosis of, 43.
Sokoloff on castration, 640.
Sokolowski on acute fibrinous bronchitis, 109.
Solanum carolinense in epilepsy, 814; in tetanus neonatorum, 753.
Solanum paniculatum, 1140.
Solid ovarian tumors, 664.
Solly on tuberculosis, 33.
Solowieff on puerperal sepsis, 540.
Somatose in anemia, 95; as a galactagogue, 1140.
Somers on purulent otitis media, 974.
Sommer on echinococcus-disease, 197.
Sommerfeld on cow's milk, 746.
Somnolence in hepatic disease, 182.
Sore throat, epidemic of, 64.
Souchon on exploration of the brain, 392; on multiple aneurysms, 147, 341; apparatus, 242, 247.
Sounding, 406.
Sourdille on keratitis, 939.
Sous on dislocation of the lens, 938; on keratitis, 938; on optic atrophy, 934.
South, fevers of the, 30.
Southam on fracture of the neck of the femur, 362; on hernia in children, 281.
Southgate on red blood-corpuscles, 1163.
Spalinger on hydrocele, 407.
Spanopnea, 117.
Spanton on splenectomy, 313.
Spartein in puerperal eclampsia, 519.
Spasm, chronic, of the pharynx, 1017; hysteric, of the trunk-muscles, 809.
Spaulding on cataract, 938.
Spear on the thyroid gland, 968.
Special hospitals for tuberculosis, 32; senses, organs of, 1154.
Specific gravity of the blood, 673; of the gastric juice, 155; immunity-reaction of the typhoid-bacillus, 728.
Specificity of bacteria, 711.
Speech, disturbance of, from anemia, 849.
Speck on muscular energy, 1171.
Spencer (G. W.) on eucain, 234; on mammary abscess, 213; on pathology of bone, 884.
Spengel on tuberculous glands, 221.
Spengler on tuberculosis of the larynx, 1026.
Spermatozoa, vitality of, 452.
Sphincter, Hennig's, 658, 659.
Sphincteric dilatation for constipation, 168.
Sphygmograph, 123.
Sphygmomanometer, 122.
Spicer on papilloma of the nose, 1004.
Spiegler on a pernicious skin-disease, 1046; test for albumin, 1192.
Spillmann and Etienne on mercurial multiple neuritis, 827.
Spina bifida, treatment of, 382.
Spinal brace, 875; caries and the Röntgen rays, 425; column, diseases of, 394; -cord changes in gastric carcinoma, 684; -disease and neuritis, 830; diseases of, 394; painless tumor of, 854; in pernicious anemia, 850; physiology of, 1178; lesions caused by tetanus-toxin, 689; sclerosis in children, 794.
Spine, acute osteomyelitis of, 394; in children, 876; diseases of, 875; fracture-dislocation of, 397; irritable, 812.
Spitta on young primiparæ, 455.
Spleen, diseases of, 311; enchinococcus of, 314; enlargement of, in hepatic cirrhosis, 178; -extract in chlorosis, 1107; in malarial cachexia, 1107; fetal, in puerperal eclampsia, 516; form of, 1151; hydatid disease of, 314; hypertrophy of,

in malarial fever, 54; in infectious diseases, 703; lymphosarcoma, 668; in pernicious anemia, 98; in tuberculosis, 775; wandering, splenopexy for, 314.
Splenectomy, 313.
Splenic enlargement in hepatic cirrhosis, 178; extract in exophthalmic goiter, 143; leukemia, 101.
Splenopexy, 314.
Splenorrhaphy, 313.
Splint, hip, 882; nasal, 1007.
Splinting, 356.
Sponge-grafting in sympathetic ophthalmia, 921; in abdominal operations, 212.
Spontaneous cure of rachitic curves, 889; disappearance of abdominal tumors, 275; dislocation of the hip-joint, 372; evolution, 532; perforation of the medial plate of the mastoid, 979; rupture of the mastoid cells, 980; of the umbilical cord, 461; of the uterus, 477.
Sporadic cretinism, 825; goiter, 150.
Sporozoites, 1077.
Sprigg on double uterus, 595; on pregnancy in uterus didelphys, 477.
Spring catarrh, 915.
Springer on cardiac hypertrophy, 787.
Sprains, 371.
Spurrell on pneumonia, 113.
Spurs, nasal, electrolysis of, 1007.
Sputum, nitrogen in, in tuberculosis, 34; in pertussis, 697; protozoa in, 743; starch in, 109; trichomonas pulmonalis in, 743; in tuberculosis, 36.
Squeezing out the placenta, 507.
Squibb on izal, 1126.
Squint, amblyopia without, 900; convergent, 904.
Stabb on lupus of the larynx, 1025.
Stabel on exophthalmic goiter, 142; on goiter, 150.
Stab-wound of the pericardium, 339; of the pregnant uterus, 479.
Stacke on acute otitis media, 966; on excision of the ossicles, 978.
Stacke's operation, 982.
Stadelmann on lumbar puncture, 856.
Stadfeld on pelvic hematocele, 544.
Stadfelt on myopia, 898.
Stahl (F. A.) on prolongation of pregnancy, 482.
Staining of diphtheria-bacilli, 737; of flagella, 737.
Stamford, Conn., typhoid fever at, 19.
Stammering, 1028; due to adenoids, 1011; from eye-strain, 894.
Stanton on placenta prævia, 483.
Stapes, removal of, 981.
Staphylococcus albus in milk, 546; pyogenes albus in nephritis, 191.
Staphylomycosis, 742.
Stapleford on rupture of the membranes, 461.
Staples on statistics of labor, 503.
Starch in sputum, 109.
Stark on sterilized milk, 548; on tuberculous cervical glands, 716.
Starkey on asthenopia, 902; on latent astigmatism, 896.
Starling on coagulation of the blood, 1162; on dropsy, 129; on lymph-formation, 1165; and Leathes on absorption, 1166.
Starr (L.) on brain-surgery, 392; on exophthalmic goiter, 143; on scarlatinold eruptions, 765; on scurvy, 779.
Starvation temperature, 752.
Statistics of albuminuric retinitis, 945; of anesthesia, 248; of cataract, 938; of cystic degeneration of the chorion, 462; of diabetes mellitus, 82, 83; of diphtheria, 758; of forceps operations, 534; of general paralysis, 868; of hepatic abscess, 315; of intubation, 1023; of intussusception, 310; of Johns Hopkins Hospital, 27; of labor, 502; of malarial fever, 56; of placenta prævia, 483; of pneumonia, 111; of rheumatoid arthritis, 76; of splenectomy, 314; of strabismus, 904; of strangulated hernia, 282; of symphysiotomy, 536; of tracheotomy, 337; of tuberculosis, 31; of typhoid fever, 26; of vaccination, 49.
Staude on dermoid cyst in pregnancy, 479.
Stavely on fibromyoma in pregnancy, 481.
Stchegoleff on tuberculous peritonitis, 277.
Stcherbak and Ivanoff on polyesthesia, 811.
Steam as a hemostatic, 211; in metrorrhagia, 588.
Stearates of the alkaloids, 1140.
Stebbings on quinin-eruption, 1052.
Steele on erysipelas in children, 777; on sarcoma of the kidney, 800.
Steffan on conjunctivitis, 916.
Steffen's (W.) mixture, 748.
Steil on fat, 1173.
Stein and Erbmann on leukocytes, 93.
Steinach and Wiener on vasomotors, 1167.
Steinbrügge on cholesteatoma of the ear, 978.
Steiner on pigment-adenoma of the conjunctiva tarsi, 916; on pterygium, 917.
Steinlechner on Graves' disease, 838.
Steinschneider and Schaefer on the gonococcus, 725.
Steltner on secondary abdominal pregnancy, 498.
Stengel (A.) on acute endocarditis, 125; on fever in nephritis, 193; on marrow-extract, 1107; on pernicious anemia, 99.
Stenosis of the aorta, 148; bronchial and tracheal, 110; esophageal, 151; of the larynx, 1022; mitral, 130; of the nares, etiology, 1006; pulmonary, 132.
Stephani on exophthalmic goiter, 352.
Stephens on dysentery, 311.
Stephenson on abscess of the iris, 892; on congenital duplication of the caruncula lacrimalis, 893; on episcleritis, 918; on sex, 452.
Sterile milk, 1186.
Sterility, 451; and endometritis, 601.
Sterilization of catgut, 207; of catheters, 206; of milk, 746.
Sterilized milk, scorbutus from, 548.
Sterling on rachitis, 778.
Stern on typhoid fever, 19.
Sternberg (G. M.) on variola 47.
Stethoscope, differential, 123; ocular, 954.
Steudel on black-water fever, 55.
Stevens (A. A.) on typhoid fever, 21.
Stevens (E. W.) on strabismus, 902; on the tropometer, 903.
Stevenson and Michael on aneurysm, 341.
Stewart (G.) on lupus of the larynx, 1025; on multiple neuritis, 830; on muscular energy, 1172; on rheumatism, 72; on tuberculosis of the tonsils, 1015.
St. George's Hospital, abdominal section in, 306.
Sticker on chromic-acid poisoning, 1113; on chronic pharyngitis, 151.
Stieda on gynecomastia, 1159.
Stienon on leukocytosis, 92; on pneumonia, 112.
Stiles (H.) on tuberculous peritonitis, 275.
Stillson on cataract, 935.
Stimson (L. A.) on malignant tumors, 254.
Stinging nettle, 1120.
Stitch-abscess, origin of, 212.
Stocker on Alexander's operation, 607; on ovarian cyst, 660.
Stockman on chlorosis, 96, 97; on iron, 1174; on pernicious anemia, 98.
Stockton on Addison's disease, 106; on cardiac disease, 128; and Williams on fat-necrosis, 183.
Stoewer on conjunctival hemorrhage, 917.

Stoker on excision of the knee-joint, 375; on ozena, 1000; on quintuplets, 530.
Stokes on Bier's treatment, 376; on diphtheria, 723, 755; on fractures of the femur, 358; on Gritti's amputation, 230.
Stokes's classification of fractures of the femur, 359.
Stomach, carcinoma of, 167, 269; in catarrh of the nasopharynx, 1010; changes in form and position, 157; dilatation of, 164; diseases of, 152, 266; "fasting," 162; functional disorders, 158, 161; healthy, contents of, 1186; hour-glass contraction of, 167, 272; hydrochloric acid of, 1186; lavage of, 163; methods of examination, 152; mycoticopeptic ulcer of, 692; neurotic disturbances, 161; round ulcer of, 266; -test in murder-trials, 1185; tumors of, 692; ulcer of, 165.
Stomatitis aphthosa, 691.
Stone in the bladder, 404; in the cystic duct, 319; Memphis, 239.
Stone on atresia of the vagina, 565; on fetal malformations, 468.
Stools in typhoid fever, 25, 26.
Stoos on antispasmin, 1108; on thrush, 691.
Story on cataract, 938; on lacrimal obstruction, 910; on sarcoma of the ear, 976.
Story's operation, 907.
Stowers on dermatitis repens, 1045.
Strabismus, 902, 904.
Straightening, forcible, of the knee, death after, 883.
Stramonium-poisoning, 931.
Strangulated hernia, 282; ovarian cysts, 661.
Strangways on hay fever, 1002.
Strassmann on antitoxin, 763; on suspensio uteri, 522; on vaginitis, 556.
Stratz on the pelvis in primitive races, 453.
Strauss on gaseous fermentation, 165; on gastric carcinoma, 168; on the gastric juice, 154, 155; on gastric ulcer, 166; on hydrochloric acid, 153; on tuberculosis, 38.
Strauss's glanders-reaction, 716.
Strehl on equilibration, 1181; on hearing, 1181.
Strength of alkaloidal tinctures, 1101.
Streptococcæmia acutissima, 62.
Streptococcism in pregnancy, 474.
Streptococcus infection through the placenta, 457; -pneumonia, 697; pyogenes, 714; in puerperal sepsis, 540; in scarlatina, 768; virulent cultures of, 737.
Stricker on bronchitis, 109; on sympathetic ophthalmia, 920.
Stricture of the female urethra, 575; of the nasal duct, 943; of the pylorus, 268; syphilitic, of the rectum, 327; of the urethra, 397.
Stroganoff on bacteriology of the cervix uteri, 570.
Strong on intubation, 1023.
Strophanthin in cardiac disease, 137.
Strophanthus in angina pectoris, 140; in cardiac disease, 137; in summer diarrhea, 783; in valvular cardiac disease in pregnancy, 470.
Strouse on abortion, 487; on trachoma, 915.
Strubing on pulmonary neuroses, 116.
Structure of the arterial wall, 1148.
Strümpell on asthenic bulbar paralyses, 847.
Struma exophthalmique fruste, 142.
Strumitis, diplococcus-, 703.
Strychnin in alcoholism, 823; in asthenopia, 902; in hemeralopia, 924; in optic atrophy, 934; in pulmonary edema, 114; in quinin-amblyopia, 931; in summer diarrhea, 783; in tic douloureux, 817; in tuberculosis, 36, 37; in valvular cardiac disease in pregnancy, 469.
Stuart on asepsis in labor, 503.
Stubbs on cornual pregnancy, 508.
Studensky on urobilin, 1191.
Stühlen on iron, 1174.
Stüve on oil of sesamum, 1138.
Stuttering, 1028.
Stutz on eosinophile cells, 670.
Stye, 907.
Stypticin as a hemostatic, 343, 1141; in metrorrhagia, 590.
Subconjunctival angioma cavernosum, 917; injections, 941.
Subcutaneous abscesses in croupous pneumonia, 113; emphysema during labor, 527; injections of fat, 1119; wiring of the patella, 363.
Subhyoid pharyngotomy, 332.
Subjective visual perceptions, 929.
Sublimate injections, intravenous, 1097.
Subluxation of the knee-joint, 375.
Submammary abscess, 546.
Submaxillary abscess, 690.
Subphrenic abscess, 173, 267, 306.
Subtendinous exostosis, 265.
Sudden maternal death during labor, 528.
Suffocative laryngitis in varicella, 772.
Sugar as an antiseptic, 211, 217; Elliott's test for, 1193; in gastric ulcer, 166; glycosuria from, 1120; phenylhydrogen test for, 1193; picric-acid test for, 1194; in the urine, 1175, 1192, 1193.
Suker on ephedin hydrochlorate, 920.
Sulfonal, 1142; exanthemata, 1054; in hiccough, 1142; in urine, 1195.
Sultan on the thymus gland, 1160.
Sulzer on the passage of particulate elements through the diaphragm, 740.
Summer diarrhea in children, 783.
Summont and Vennersch on veratrol, 211.
Sunlight, effect of, on tubercle-bacilli, 716.
Superfetation, 530.
Superficial erythemata, 1030; nerves of the head, 1153.
Superinvolution of the uterus, 510, 544.
Superior rectus, paralysis of, 900.
Supernumerary digits, 468, 1159; mammæ, 546; ovaries, 666.
Suppression of urine, 185.
Suppuration of the amniotic fluid, 462; and microorganisms, 713; of the middle ear, 974; pelvic, in pregnancy, 476.
Suppurative adenitis of the groin, 217; arthritis after erysipelas, 377; disease of the pelvic viscera, 641; joint-lesions of scarlet fever, 376; mastoiditis, treatment of, 965; nephritis, 191, 701.
Supraclavicular adenopathy in intraabdominal carcinoma, 307.
Supracondyloid process of the humerus, 1148.
Suprapubic cystotomy for vesical hemorrhage, 399; lithotomy, intraperitoneal, 404.
Suprarenal capsules, 1168; extract in Addison's disease, 104; rests, 196; kidney-tumors derived from, 701.
Suprathyroid laryngotomy, 332.
Surgery, abdominal, 323; antiseptic and aseptic, 200; of the brain, 388; conservative pelvic, 654; general, 200; intratympanic, 972; of the lung, 328; of the middle ear, 981; military, 429; in nasal disease, 997; orthopedic, 872; plastic, 416; pulmonary, 328; transvaginal, 644; of the vermiform appendix, 290.
Surgical aspect of tuberculosis, 221; diseases of children, 875; infectious diseases, 742; treatment of gall-stones, 181; tuberculosis, 221.
Surveyor and Harley on intestinal antisepsis, 173.
Suspensio uteri, 613; labor after, 522.
Sutherland on appendicitis, 170.

Sutphen on glaucoma, 923.
Sutton (B.) on cysts of the thyroid, 351; on median cervical fistula, 353; on ovarian cysts, 662; on sarcoma of the femur, 265; on splenectomy, 313; on the ureter, 411.
Suture, arterial, 343; buried, 203, 209, 651; of fractures, 358; immediate, of gall-ducts, 319; -material, 209; tendon, 203; of veins, 342.
Swain on otitic meningitis, 994; on toxin-treatment of malignant tumors, 254.
Swan on club-foot, 885.
Swanzy on orbital tumors, 911.
Sweeny (F. H.) on symphysiotomy, 535.
Sweet on typhoid fever, 22.
Sweetman on tympanites, 305.
Swelling of the parotid gland, 350.
Swift on pneumonia in children, 790.
Swinburne on deafness, 1003.
Swindells on tetanus, 843.
Sycosis, parasitic, 1081.
Symmetric acrosphacelus without Raynaud's phenomena, 1056.
Symonds on hernia in children, 281.
Sympathetic glaucoma, 923; nerves, 1180; ophthalmia, 920, 921.
Symphysiotomy, 534.
Symphysis pubis, 536.
Symptomatic anemia, 93, 94.
Synovitis after erysipelas, 377; of the knee, 882.
Synthetic remedies, 1142.
Syphilis, 1088; antitoxin in, 1095; and atheroma, 147, 683; of the heart, 146; of the cerebral arteries, 682; in children, 776; congenital, 380, 1090; of the conjunctiva, 917; of the ear, 971; encephalic, 948; erysipelas in, 1096; eye in, 947; hypodermic injections of mercury in, 1096; infantile, 1088; inherited, contagiousness of, 1089; iodids in, 1097; and jaundice, 175; and lardaceous disease, 1093, mercuroiodohemol in, 1127; nasal, 1006; of nerve-centers in children, 793; ocular, 947; of the orbit, 912; of the pharynx, 1016; professional, 1092; serotherapy for, 1094; teeth in, 151; thyroid gland in, 1095; of the tonsils, 1016; toxin-theory of, 1093; transmission of, 777; and tuberculosis, 1093.
Syphilitic aortitis, 682; chancres of the urethra, 1099; cicatrices, 1091; condylomata of the ear, 960; deafness, 973; joint-diseases, 776; joint-disease in children, 381; oculomotor palsy, 776; opthalmoplegia, 905; optic neuritis, 932; reinfection, 1098; retinitis, 928; stricture of the rectum, 327.
Syphilitoxin, 1094.
Syphiloma of the nose, 1091.
Syringing in purulent otitis media, 974.
Syringomyelia, 859; eye in, 947; lepra-bacilli in, 686; and Morvan's disease, 859; skin-lesions of, 1056.
System, circulatory, diseases of, 121; vascular, tuberculosis of, 43.
Systolic aortic murmur in anemia, 94.
Szenes on caries of the antrum, 979; on infection of the ear, 960.
Sziklai on diphtheria, 764; on pneumonia, 113; treatment, 113.
Szumann's saline solution, 432.

Tabes dorsalis, 851.
Tabic amyotrophy, origin of, 686.
Tachycardia and exophthalmic goiter, 837, 838; at the menopause, 593; from nasal polypi, 1004; paroxysmal, 139.
Tait (L.) on dysmenorrhea, 590.
Taka diastase, 1143.
Talalgia, pathology of, 742.
Talipes, 885.
Talley (F. W.) on metritis, 597.
Talma on the stomach, 153.
Tampon, antiseptic, 431.
Tandler on the humerus, 1148.
Tangl on metabolism, 1177; and Harley on the liver, 1170.
Tangling of the umbilical cord, 461.
Tannalbin, 1143.
Tannic acid in herpes pudendalis, 555; in summer diarrhea, 784.
Tannigen, 1143; in children, 802.
Tannoform, 1084.
Tansley on acute otitis media, 967; on congenital ptosis, 908; on iritis, 919.
Tapeworm, 197.
Tappeiner on quinin-derivatives, 1135.
Tappey on peritoneal adhesions, 655.
Taritoni on splenectomy, 314.
Tarnier on symphysiotomy, 536.
Taste, sense of, in rachitic children, 778.
Taty on epilepsy, 813, 1111.
Taube on anemia, 95.
Tavel's solution, 212, 503.
Taxis in hernia, 279.
Taylor (T. E.) on cataract, 938. on iodoform-injections, 879; on pseudochancre, 1099; on sarcoma of the brain, 689; on symphysiotomy, 535.
Tchukoff on vasomotor edema, 149.
Teacher's nodes, 1029.
Tears, 908.
Tecce on influenza, 51.
Technic, pathologic and bacteriologic, 736.
Teeth, carious, lacrimation due to, 909; and tuberculous cervical glands, 716; congenital, 781; and ears, 962; extraction of, hemorrhage after, 344; and the eyes, 949; effects of nutrition upon, 782; in syphilis, 151.
Teevan's law, 447.
Teichmüller on pernicious anemia, 850.
Teillas on retinal detachment, 928.
Teissier on tuberculosis, 35; on typhoid fever, 718.
Temperature in chloroform-narcosis, 243; in rheumatism, 71; in scarlatina, 769; sensations, 1182; starvation, 752; in typhoid fever, 22.
Temporal bone, cholesteatoma of, 977; lobe, bicameral abscess in, 992.
Temporary hemostasis, 430.
Tenacity of the diphtheria-bacillus, 722.
Tenderich on tuberculosis of hernia, 220.
Tenderness of the toes in typhoid fever, 22.
Tendon, diseases of, 354, 888; dislocation of, 356, 888; of fingers, injuries to, 355; kangaroo-, 203; of the quadriceps extensor femoris, rupture of, 354; sutures, 203; buried, 209; -transplantation, 886.
Tenotomy, 903; conjunctivitis, after, 916.
Tension, regenerative, 707.
Teplyachine on the cornea, 892.
Teratomata, 705.
Terrier on angiocholitis, 322.
Terson on iritis, 919; on pseudomembranous conjunctivitis, 915.
Test-letters, size of, 893; -meals, 152; shadow, 954.
Testicle, 1170; diseases of, 406.
Tetanus, 840; after abortion, 841; antitoxin in, 840; chloral hydrate in, 843; chloralamid in, 843; from eye-injury, 953; gelsemium in, 843; after labor, 515; neonatorum, 548, 753, 841; puerperal, 541; after puerperal eclampsia, 515; -toxin, spinal lesions caused by, 689; veratrum viride in, 843.
Tetany, 838; in children, 778; gastric, 839; and hysteria, 810; infantile, 839; papillitis in, 838; thyreoidin in, 839.
Tetracoccus versatilis in yellow fever, 714.
Tetragenus-septicemia, 714.
Thallinger on vaginal cyst, 560.
Thayer on acromegaly, 845; on acute pancreatitis, 183; on diabetes mellitus, 84; on osteoarthropathy, 108; and Blumer on acute endocarditis, 124.

Theilhaber on the menopause, 592.
Theobald on heterotropia, 903.
Theobromin, 1114; in cardiac disease, 138; salicylate, 1143.
Theodor on pertussis, 773.
Theodoroff on the conjunctival glands, 1155.
Theoform in corneal ulcer, 940.
Therapeutics, experimental, 1100.
Thérèse on bulbar paralysis, 834.
Thermal fever, 18.
Thermocauterectomy, 637.
Thieberge on psoriasis, 1036.
Thiemich on the blood in typhoid fever, 718; and Papiewski on Gärtner's mixture, 747.
Thierry on asphyxia, 1030; on burns, 417.
Thiersch grafts in ectropion, 908.
Thin (G.) on endemic fever, 64; on malarial fever, 53, 57.
Thin's method, 53.
Thiol in vulvitis, 554.
Third coronary artery of heart, 1148; stage of labor, 507.
Thirst after abdominal section, 658.
Thistle on typhoid fever, 30.
Thoinet and Masselin on infantile paralysis, 794.
Thomalla on dacryocystitis, 909.
Thomas (W. G.) on advancement, 903; on cut-throat, 342; on puerperal tetanus, 541; on rupture of tendons, 355; on syringomyelia, 860; and Roux on motor aphasia, 1028.
Thompson on deafness, 1003; on tetany, 778; on typhoid fever, 292.
Thomson (A.) on peritoneal tuberculosis, 274; on secondary abdominal pregnancy, 498; on ovarian cyst, 660.
Thomson (S. C.) on bronchitis, 110; on diphtheria, 759, 761; on the middle ear, 962; on myxoma of the larynx, 1025; on nasal antiseptics, 996; on tetany, 838; and Hewlett on bacteria in the nares, 713, 998.
Thoracic deformities, 108; duct, injury of, 348.
Thoracopagus, 466.
Thorburn and Westmacott on osteoarthropathy, 108.
Thorington on lenses, 899.
Thorne on auscultatory percussion, 123; on cardiac disease, 135.
Thornhill on the anchylostoma, 197.
Thornton on carcinoma uteri, 632.
Thorsch on leukemia, 677.
Thrasher on necrosis of the middle turbinated, 1009.
Thread-worms, glycosuria due to, 780.
Threatened abortion, 488.
Thresh on sore-throat, 64.
Throat-affections of influenza, 51; -inflammation, septic, 1013; mycosis of, 1016.
Thrombophlebitis, orbital, 911.
Thrombosis, 148; in croupous pneumonia, 113; of the heart, 680; of the iliac veins in typhoid fever, 23; of the veins in influenza, 52.
Thrush, 690.
Thudicum on the alkaloids of the urine, 1195; on carbohydrates in the urine, 1195; on hypoxanthin, 1195; on urea, 1194.
Thue on pleuritis, 699.
Thumb, injuries of, 374; method of bandaging, 204.
Thursfield on tetanus, 842.
Thymol in anchylostomiasis, 198; in chyluria, 198.
Thymus gland, 1160; in exophthalmic goiter, 143.
Thyreoantitoxin, 88, 1105.
Thyreoidismus, 1105.
Thyreoiodin, 1105, 1169; in tetany, 839.
Thyroid, accessory, 351; cyst, 1017; desiccated, thyroid extract in, 1018; extract in Addison's disease, 1106; in cicatricial keloid, 264; in cretinism, 781, 824; in desiccated thyroid, 1018; in epilepsy, 815; in exophthalmic goiter, 142, 1104; in goiter, 150, 1104; in keloid, 1104; in melancholia, 1104; in the menopause, 658; in myxedema, 89, 824, 1104; in obesity, 88, 1104; in pityriasis rubra pilaris, 1079; in psoriasis, 1036; in tetany, 839; -feeding in insanity, 869; gland, 968, 1169; adenoma of, 351; administration of, 89; carcinoma of, 351; cysts of, 351; diseases of, 149, 351, in syphilis, 1095; treatment, 89.
Thyroidectomy, partial, 1019.
Thyroidin, 89; in exophthalmic goiter, 142; in goiter, 150.
Thyroidism, 89, 150, 1104.
Thyroiditis, acute, 149.
Thyroiodin, 1105.
Tibia, intrauterine fracture of, 466.
Tic douloureux, 817.
Tiffany on dislocation of the lens, 938; on ectopia lentis, 892.
Tigerstedt on the heart, 1168.
Tighe on rupture of the uterus, 525.
Tiktin on infectious diseases, 703.
Tillaux on vaginal cyst, 560.
Tilley on parosmia, 1003.
Tillmanns on antiseptics, 201; on carcinoma, 263.
Timmermann on tetanus, 841.
Tingley on superinvolution of the uterus, 544.
Tirard on tetanus, 840.
Tire, retinal, and hysteria, 925.
Tison on erysipelas, 50.
Tissue, conservation of, with formalin, 738.
Titone on quinin in pregnancy, 485.
Tizzoni's antitoxin in tetanus neonatorum, 753; and Cattani on infectious diseases, 703.
Tobacco-amblyopia, 932.
Tobeitz on acute otitis of measles, 964.
Tochtermann on culture-media, 737.
Todd on fetal malformations, 468.
Töpfer's reagent, 153.
Tœplitz on acute otitis media, 965.
Toes, papillary ridges of, 1158; tenderness of, in typhoid fever, 22.
Toluylendiamin, jaundice from, 693.
Tomasoli on syphilis, 1094.
Tomatoes, cardiac arrhythmia due to, 139.
Tompkins (H. H.) on carbuncles, 219; on inflammation of the lingual tonsils, 1013.
Tonsils, chronic disease of, 1015; and diphtheria, 757; lingual, acute inflammation, 1013; lingual, and cough, 107; and middle-ear disease, 1014; polypoid hypertrophy of, 1015; syphilis of, 1016; tuberculosis of, 1015.
Tonsillitis, bacteria of, 1014; chancriform, 1014; and endocarditis, 125; guaiacum in, 1123; lacunar, 758, 1014; and rheumatism, 71–73, 1014; ulcerative, 1014.
Topical treatment of acne, 1083.
Topography of skull and ear, 979.
Torsion of ovarian cysts, 661.
Tóth on secondary abdominal pregnancy, 498.
Touatre on anemia, 95.
Toulouse on puerperal psychoses, 545.
Tourette (G.) on coffee-poisoning, 1115; on hysteric heart, 811.
Townsend on brisement forcé, 883; on chlorosis, 96, 97; on scurvy, 780; on spontaneous rupture of the uterus, 478, 525; and Chadwick on bicycling for women, 584.
Toxic amblyopia, 930; endometritis, 598.
Toxicity of the aqueous part of the breath, 742; of the urine and blood-serum in puerperal eclampsia, 516
Toxicology in children, 802.
Toxin and antitoxin, 726, 735; diphtheria, 732; of erysipelas in malignant tumors, 253; theory of syphilis, 1093; treatment of malignant tumors, 253.
Toxinemia, 742.
Tracey on tetanus, 842.
Trachea, carcinoma of, 697; con-

dyloma of, 1030; diseases of, 1030; fracture of, 1030.
Tracheal stenosis, 110; tube for vomiting, 163; tugging, 148.
Tracheotomy for asphyxia, 1030; in collapse during anesthesia, 250; in children, 337; statistics of, 337.
Trachewsky on exophthalmic goiter, 837.
Trachoma, 915; deformans, 554; of the vulva, 554.
Tract, gastrointestinal, 151; optic, decussation of, 930.
Tracy (E. A.) on splinting, 356.
Tragus-pressure, 972.
Transfusion of blood, 224; in cardiac paralysis, 249; in hemorrhage, 345; in pernicious anemia, 100.
Transhyoidean pharyngotomy. 332.
Transillumination of the antrum, 1008.
Transmissibility of carcinoma, 264.
Transmission of syphilis, 777.
Transperitoneal ligature of the common iliac artery, 341; ureterolithotomy, 412.
Transplantation, tendon-, 886; traumatic, of ciliæ, 916.
Transposition of the heart, 144.
Transvaal, gunshot wounds in, 443.
Transvaginal surgery, 644.
Transverse vaginal septum, 565.
Trantas on keratitis, 939; on retinitis pigmentosa, 927.
Traumatic dermoid cysts, 253; inflammation of the semilunar cartilages, 377; insanity, 387; mammary abscess, 214; optic atrophy, 934; perforation of the membrana tympani, 961; transplantation of ciliæ, 916.
Traumaticin, 1143.
Traumatism of the fetus, 465; of the kidney, 413; during pregnancy, 478; and tumors, 263.
Travers on ovarian cyst, 660.
Treatment, alternating, of diabetes mellitus, 86.
Treitel on bicameral abscess, 992.
Trendelenburg on exophthalmic goiter, 352; posture in funic prolapse, 533; on varices of the leg, 340.
Trephining of the cranium, 389; for epilepsy, 816.
Treub (H.) on myomohysterectomy 622.
Treupel on thyreoiodin, 1105, 1169.
Trevelyan on anterior poliomyelitis, 794; on tetanus, 842.
Treves (F.) on excision of the rectum, 326; on Glénard's disease, 323; on Gritti's amputation, 230; on laryngotomy, 332; on the surgical aspect of tuberculosis, 221.
Treymann on symphysiotomy, 534.
Tribadism, 453.
Triboudeau on tears, 908.
Triboulet on diabetes mellitus, 84.
Trichiasis, 907.
Trichinosis, 197; and dermatomyositis, 75.
Trichloracetic acid in hyperidrosis, 1084; in nasal catarrh, 787.
Trichocephaliasis in children, 196.
Trichocephalus dispar, 197.
Trichomonas pulmonalis, 116; in the sputum, 743; in the urine, 196, 743.
Trichophyton, physiology of, 1048.
Trichophytosis, 1047.
Trichorrhexis nodosa barbæ, 1085.
Trifacial nerve, 1152.
Trifiletti on otitic facial paralysis, 967; on hysteric aphonia, 974.
Trigeminal neuralgia, 818; neuralgia and nasal diseases, 1002.
Trinkler on splenectomy, 314.
Trional, 1144; in cerebral sclerosis, 802; in children, 802; in epilepsy, 814; in fever, 69; in malarial fever, 802; in measles, 802; in scarlatina, 802; in tuberculous meningitis, 802; in variola, 802.
Trosier's sign, 307.
Troitzky on sterilization of milk, 746.
Trophic nerves, 1180.
Tropical dysentery, 58; fever, 18.
Tropometer, 903.
Trousseau on keratitis, 939; on retinal hemorrhage, 926.
Trudeau and Baldwin on tuberculosis, 42.
Trunk-muscles, hysteric spasm of, 809.
Truss, 278.
Tscherewkow on lymph-formation, 1165.
Tscherneffsky on contracted pelvis, 512.
Tscherning on myopia, 898.
Tschudy on Cesarean section, 536.
Tubal abortion, 497; gestation, 490.
Tubby on deformities, 874; on orthopedic surgery, 872; on Pott's disease, 394.
Tubercle-antitoxin, 731; bacilli in the blood of newborn infants, 716; and sunlight, 716.
Tuberculin in children, 776; in tuberculosis, 42, 43.
Tuberculosis, 31, 220, 716; acute, hypoleukocytosis in, 672; alcoholic neuritis and, 829; of the alveolar processes, 716; antiseptics in, 38; antiphthisin in, 776; aseptolin in, 39; atropin in, 36; of the bladder, 403; of bone, 375, 878, 884; bromin and iodin in, 39; of the bronchial glands, 44; cardiac, 678; and cardiac arrhythmia, 139; and cardiac disease, 128; of the cervix uteri, 571, 659; in children, 33, 717, 775; contagiousness of, 31; creasote in, 37; creasote carbonate in, 45; cutaneous pemphigoid eruption in, 1040; death-rate of, 31; diagnosis, 36; and dust, 32; of the endometrium, 599; of the esophagus, 151; etiology, 31; external, 45; eye in, 951; of the Fallopian tubes, 45, 659; of the gastrointestinal tract, 43; genital, in children, 659; gold and sodium chlorid in, 36; guaiacetin in, 38; guaiacol in, 38, 39, 1122; and guinea-pigs, 36; of the heart, 678; hemorrhage in, 34; heredity in, 33; of hernia, 220; hyperpyrexia in, 39; ichthyol injections in, 39; injection of guaiacol and iodoform in, 38; intestinal, in children, 775; intestinal infection in, 44; and jaundice, 176; of joints, 375, 884; of the kidneys, 194, 415; of the kidney in children, 798; of the lacrimal gland, 909; of the larynx, 1026, 1027; leukocytes in, 93; local, 221; of the mammary gland, 717; Maragliano's treatment, 41; masked, 33; of the middle ear, 976, nasal, 1006; of the nasopharynx, 1010; in Norway, 32; ocular, 919; oil of cloves in, 39; oil of turpentine in, 221; olive oil and iodoform in, 39; of the ovaries, 45; palladium bichlorid in, 221; Paquin's treatment, 40, 41; pelvic, 45; peritoneal, 274; of the placenta, 460; placental blood in, 33; of the pleura, 44; potassium permanganate in, 39; and pregnancy, 473; prophylaxis of, 31; pulmonary in the aged, 34; pyoktanin in, 221; rectal mucus in, 43; salicylic acid in, 39; serum-therapy in, 40, 731; of the skin, 1073; of the soft palate, 43; special hospitals for, 32; spleen in, 775; sputum in, 34, 36; statistics of, 31; strychnin in, 36, 37; surgical aspect of, 221; symptoms, 33; and syphilis, 1093; of the tonsils, 1015; treatment, 36; tuberculin in, 36, 43; tuberculocidin in, 42; of the tunica vaginalis testis, 717; after typhoid fever, 775; urine in, 34; urogenital, in children, 798; of the vascular system, 43.
Tuberculous abscesses, 876; adenitis, cervical, 1017; animals, meat and milk from,

31; cervical glands and carious teeth, 716; endocarditis, 126; endometritis, 599; glands, 221; mammary abscess, 214, 215; mastoiditis, 981; meningitis, 187, 776, 793, 802; myocarditis, 678; osteomyelitis, iodoform-glycerol in, 878; ostitis and arthritis, 370; ostitis, juxtaarticular, 881; otorrhea, lactic acid in, 976; peritonitis, 44, 223; pneumothorax, 120.
Tuboabdominal pregnancy, 498.
Tuboovarian cyst, 659.
Tucker (A. B.) on congenital morphinism, 803; on retrodisplaced uteri, 609; on symphysiotomy, 535.
Tuffier on partial nephrectomy, 412; on partial thyroidectomy, 1019; on surgery of the lung, 331; on wounds of the chest, 328; and Widal on typhoid fever, 24.
Tugging, tracheal, 148.
Tuholske on pregnancy in uterus didelphys, 477.
Tuley on inanition-fever, 752.
Tumors, 252, 704; abdominal, 174; amyloid degeneration in, 706; benign, of the larynx, 1024; of the bladder, 403; and blastomycetes, 706; bleeding, of the nasal septum, 1005; of the brain, 392; of the choroid, 924; of the conjunctiva, 916; contractile, of pylorus, 166; of the cornea, 941; dermoid, of the cranial cavity, 252; etiology of, 706; of the eyelid, 907; intrathoracic, 120, 704; of the iris, 920; of the kidney, 195, 412; in labor, 521; of the lacrimal gland, 909; of the long bones after typhoid fever, 24; of the optic nerve, 935; orbital, 911; ovarian, in pregnancy, 479; painless, of the spinal cord, 854; and protozoa, 706; of the retina, 929; of the skin, 1063; of the stomach, 692; of traumatic origin, 263; of vagina and vulva, 558.
Tunica vaginalis, diseases of, 406; tuberculosis of, 717.
Turbinated, middle, necrosis of, 1009.
Turbinotomy, 972.
Turgard on vaginal cyst, 562.
Turck on gastritis glandularis chronica, 160; on the gyromele, 155; on vomiting, 164.
Turk on catarrh of the nasopharynx, 1010.
Turnbull on biliary colic, 182.
Turner (J.) on anchylostomiasis, 198; on the cornea, 938; on general paralysis, 869; on otitic sinus-phlebitis, 990; on the x-rays, 426.
Turner (W. A.) on trophic nerves, 1180; on epilepsy, 817.
Turpentine in postpartum hemorrhage, 544; in tuberculosis, 221; in typhoid fever, 29.
Tussolo, 1102.
Tuttle (A. H.) on hysterectomy in puerperal sepsis, 643; on orchitis, 380.
Tweedy on puerperal eclampsia, 518; on retinal detachment, 928.
'Tween brain, 1179.
Twin pregnancy, 529; and heredity, 530; in extrauterine pregnancy, 495.
Tympanites, 305, 660.
Tympanum, 962.
Typhlitis, 170, 171.
Typhoid-bacillus, specific immunity-reaction of, 728; in the urine, 719.
Typhoid fever, 18, 718; abortive treatment, 29; abscess of the liver in, 23; acute otitis media in, 962; albuminuria in, 21; antipyrin in, 801; antitoxic serum in, 733; bacteriology in, 718; blood in, 718; bony tumors after, 24; in the Boston City Hospital, 22; Brand method in, 26; calomel in, 770; calves' thymus in, 29; catharsis in, 30; in children, 22, 769; chills in, 20; chlorin-water in, 30; and cholera, antibodies of, 729; colon-bacillus in the urine in, 719; complications and sequels, 22; diagnosis, 18, 24; Elsner's method of diagnosis, 25; eruption in, 20; etiology, 18; gangrene after, 24; gastric juice in, 19; guaiacol in, 771; hemiplegia in, 834; hemoptysis in, 22; with hemorrhagic nephritis, 21; hepatic abscess after, 216; infection through the placenta, 457; and influenza, 52; intestinal perforation in, 28, 292; intrauterine, 18, 771; laryngeal ulcers in, 1022; liver in, 719; leukocytes in, 93; nervous sequelæ after, 24; operation in, 28; palmar abscess in, 20; peritonitis in, 23; phenacetin in, 30; in pregnancy, 19, 24; prognosis, 26; pyelophlebitis after, 179, 216; rash in, 20, 26; serum-therapy in, 28; spontaneous dislocation of the hip-joint in, 372; at Stamford, Conn., 19; statistics of, 26; stools in, 25, 26; symptoms, 20; temperature in, 22; tenderness of the toes in, 22; thrombosis of iliac veins in, 23; treatment, 26; tuberculosis after, 775; turpentine in, 28; ulceration of mouth in, 21; uremia in, 21; urine in, 26, 719; venesection in, 29; Woodbridge's method in, 29.
Typhus fever, 57; eye in, 951.
Tyrrell on gonorrheal arthritis in the newborn, 754.
Tyson on nephritis, 194.

Uhthoff on ulcer of the cornea, 940.
Ulcers, 416; of the bladder, 402; of the cornea, 939; duodenal, 170, 294; gastric, 165, 266; of the heart, 146; of the larynx in typhoid fever, 1021; mycoticopeptic, of the stomach, 692; round, of the stomach, 266.
Ulceration of the mouth in typhoid fever, 21; of the nasal septum, 1007.
Ulcerative tonsillitis, 1014.
Ulcus cornea serpens, 940.
Ulecia on twin pregnancy, 529.
Ullmann on ovarian dermoid, 663; on parasitic sycosis, 1081; on pertussis, 773.
Ulnar nerve, dislocation of, 383.
Umbilical cord, coiling of, 461; ligation of, 509; prolapse of, 533; spontaneous rupture of, 461; tangling of, 461.
Umbilicus, lymphatics of, 1149; position of, 639.
Uncooked milk and cholera-bacilli, 1186.
Uncrossed hemiplegia, 833.
Unilateral asymmetry, congenital, 745.
Uninterrupted anesthesia, 247.
Unna on chancroid, 1098; on molluscum contagiosum, 1060; on piedra nostras, 1084.
Unruptured hymen and pregnancy, 520.
Unverricht on fever, 67; on pneumothorax, 120.
Upham on uterine carcinoma, 632.
Uranium nitrate in diabetes mellitus, 87.
Uratic diathesis and typhlitis, 171.
Urbantschitsch on the ear, 969; on optic aphasia, 949; on otorrhea, 976.
Urea, 1173; as a diuretic, 194; in hepatic cirrhosis, 178; hypochlorite or hypobromite method of estimating, 1194; in the uric-acid diathesis, 186.
Uremia, 192; febrile, 193; metritis in, 596; in typhoid fever, 21.
Uremic aphasia, 193; bullous dermatitis, 1050.
Ureter, 411; anastomosis of, into the bladder, 411; carcinoma of, 700; catheterization of, 582; diseases of, 410; implantation of, into the bladder, 412; implantation of, into the intestines, 412; ligation of, 623.
Ureteral disease, diagnosis of, 581.
Ureteritis, gonorrheal, 556.
Ureteroabdominal fistula, 575.
Ureterolithotomy, transperitoneal, 412.
Ureterovaginal fistula, 573.
Urethra, anomalies of, 576; chancre of, 1099; diseases of,

397, 575; female, stricture of, 575; flushing the, 398; malformation of, 1156; rupture of, 398; senile stricture of, 576; stricture of, 397.
Urethritis, gonorrheal, 556; methylene-blue in, 379.
Urethrotomy, external, 397.
Urethroureteral anastomosis, 574.
Uric-acid concretions, 186; deposits, 1189; diathesis, 186; elimination and leukocytosis, 700; excretion in chronic lead-poisoning, 80; gravel, 1189; and leukocytosis, 92; renal deposits of, 1144; sodium salicylate and, 1137; and the xanthin bases, 77, 1173.
Uricedin, 1145.
Urinary analysis in gynecology, 580; calculus, 1190; organs, diseases of, 575; pigments, 1191; tract, diseases of, 699.
Urine, 1174; acetone in, 187; and acidity of the gastric juice, 185; albumin in, 188; albumose in, 189; alkaloids of, 1195; analysis, 1190; after anesthetics, 245; bacteria in, 190; bile-pigment in, 1191; carbohydrates in, 1195; chloroform in, 1191; culture-media, 737; in diabetes mellitus, 84; diacetic acid in, 187; digestive alkalinity of, 185; disorders of, 185; and gastric acidity, 154; hemoglobin in, 190; incontinence of, 576; nucleoalbumin in, 1192; oxalic acid in, 187; pentose in, 190; retention of, in children, 796; retention of, in a fetus, 533; in rheumatism, 70; sugar in, 187, 1175, 1192, 1193; sulfonal in, 1195; suppression of, 185; toxicity of, in puerperal eclampsia, 516; trichomonas in 196, 743; in tuberculosis, 34; in typhoid fever, 26, 719.
Urinometer, 1175.
Urobilin, 1191.
Urogenital tuberculosis in children, 798.
Urospectrin, 1191.
Urotropin, 1145.
Urquhart on the mastoid in diabetes, 980.
Urtica urens, 1120.
Urticaria, calcium chlorid in, 1032.
Uterine anomalies, 593; curettage, 602; displacements, 604; displacements in pregnancy, 475; fibroid, 616; and cardiac disease, 621; hemorrhage, 588; inflammation, 595; prolapse, 605; in pregnancy, 475.
Uterus, adolescent, 510; atresia of, after curettage, 603; atresia of, at the menopause, 593; atrophic, 510; carcinoma of, 626; congenital absence of, 595; cordiformis, 595; didelphys, 477; double, 594; double, pregnancy in 476; fetal, 510; fibroid tumor of, 616; fibromyoma of, in pregnancy, 480; gonorrhea of, 600; hyperinvolution of, 510; igniextirpation of, 637; infantile, 510; influence of castration on, 640; lateral displacement of, 604; malignant adenoma of, 630; malignant disease of, 623; normal position of, 604; perforation of, after abortion, 486; pregnant, bullet-wound of, 478; prolapse of, 605; retrocession of, 606; retrodisplacement of, 606; retroflexion of, 607; retroposition of, 606; revision of, after labor, 507; rupture of, 525; sarcoma of, 623; spontaneous rupture of, 477; superinvolution of, 510, 544.

Vaae on foreign bodies in the nose, 1006.
Vaccination, 47–49; in pertussis, 774.
Vaccine pustule on the eyelid, 907.
Vaccinia, 45, 47, 48; immunity by intrauterine transmission, 49.
Vacher on acute otitis media, 967; on ophthalmia neonatorum, 914.
Vacquez and Marcano on hemoglobinuria, 190.
Vagal nucleus, 1154.
Vagedies on variola, 46.
Vagina, absorptive power of, 555; atresia of, 565; chromic acid, poisoning from, 1113; cyst of, 560; duplex, 477; fibroma of, 562; hematic cyst of, 562; primary carcinoma of, 563; sarcoma of, in children, 800; tumors of, 558.
Vaginal celiotomy, 609; for extrauterine pregnancy, 494; 502; drainage, 652; fixation, 522; hysterectomy, 620, 636; for diseased adnexa, 648; fistula after, 573; incision for pelvic disease, 644; seborrhea, 556; secretion in the newborn, 548; in the nonpregnant, 555; septum, transverse, 565.
Vaginismus, 558.
Vaginitis, 556.
Vaginofixation, 610; dystocia after, 524; intraperitoneal, 613.
Vagitus uterinus, 465.
Vahle on the vaginal secretion in the newborn, 548; on vulvovaginitis, 797.
Vaillard on heredity, 727.
Valenta on puerperal insanity, 472.
Valerian in diabetes mellitus, 86.
Vallas on transhyoidean pharyngotomy, 332.
Valude on the eye in tuberculosis, 951; on myopia, 898; on tumor of the orbit, 912.
Valvular cardiac disease in pregnancy, 468; chronic, 127; compensation in, 678.
Vance on the hip-splint, 882.
Van der Berg on corneal ulcer, 940.
Van der Veer on tuberculosis of the cervix uteri, 659.
Vandervelde on the action of poisons on the kidney, 700.
Van der Willigen on anal fissure, 327; on smallpox in pregnancy, 473.
Van de Warker on pelvic disease, 642.
Van Duyse on corectopia, 892; on keratoplasty, 941; on tumors of the orbit, 912; on the x-rays and the eye, 953.
Van Fleet on cycloplegia, 900.
Van Hook (W.) on drainage, 652; on infiltration-anesthesia, 235; on perforation in typhoid fever, 293.
Vanillin-reaction of eosinophile cells, 668.
Van Meerdervoort on menstruation, 586.
Van Millingen on trachoma, 915.
Van Oordt on bulbar paralysis, 834.
Vansant on epistaxis, 1002.
Van Tussenbroek on galactorrhea, 546.
Vanverts on tracheotomy, 250.
Vargas on pertussis, 774.
Varicella, 772; parasites of, 1047; suffocative laryngitis in, 772.
Varices of the leg, 339.
Varicose aneurysm, 147.
Varieties of uterine carcinoma, 630.
Variola, 45; trional in, 802.
Variolization, 57.
Variot on intubation, 1023.
Varnier on the x-rays in obstetrics, 458.
Vascular changes in tuberculous meningitis, 687; system, diseases of, 338; tuberculosis of, 43.
Vas deferens, diseases of, 406.
Vaselin, acetanilid-, 657; in otitis media, 971.
Vasomotor edema, 149; nerves, 1166.
Vassali on sextuplets, 530.
Vatin on cardiac disease, 137.
Vaughan on the nucleins, 1128; on tuberculosis, 31; and Perkins on food-infection, 66.
Veal, amblyopia from, 931.
Veasey (C.) on episcleritis, 918; on the protection-rack, 954.
Vedeler on lipoma, 708.
Vegetable milk, 749.
Vegetation, adenoid, in the nasopharynx, 968.
Veillon and Hallé on vulvovaginitis, 797.
Veins and arteries, communications between, 1148; suture of, 342; wounds of, 342.

Veit on curettage, 603; on drainage, 653; on endometritis in pregnancy, 475; on epidermidalization, 625; on malignant adenoma of the uterus, 630; on rachitic curves, 889; on uterine carcinoma, 629; on vaginal cyst, 560.
Velde on dystocia after ventrofixation, 522.
Velhagen on chancre of the lid, 907.
Venables on statistics of labor, 503.
Venay on tetanus after labor, 575.
Venereal diseases, 378.
Venesection, 95; blood after, 672; in endometritis, 601; in puerperal eclampsia, 519; in typhoid fever, 29.
Venous cirrhosis, 679.
Ventral fixation, 613; hernia after abdominal section, 656.
Ventricles, laryngeal, function of, 1021.
Ventricular septum, patent, 144.
Ventrofixation, 613; dystocia after, 522.
Veratrol as an antiseptic, 211.
Veratrum viride in puerperal eclampsia, 517; in tetanus, 843.
Verchère on inversion of the uterus, 527.
Verdos on ear-disease, 970.
Vermes, 196.
Vermiform appendix, surgery of, 290.
Vernal catarrh, 915.
Verruca necrogenica, 1074.
Version, placental, 508.
Vertebra, caries of, 396; cervical, fracture of, 396.
Vertebral artery, aneurysm of, 341; puncture in general paralysis, 869.
Vertigo, ear-, 970; and the eye, 902; of nasopharyngeal origin, 1011.
Vesical calculus, 404; in pregnancy, 480; hemorrhage, suprapubic cystotomy for, 399.
Vesicofixatio uteri, 611.
Vesicovaginal fistula, 572.
Vialet on the eye, 947; on retinal hemorrhage, 926.
Vian on purulent ophthalmia, 942.
Viana on diagnosis of fracture, 358.
Vibration of the vocal bands, 1029.
Vibrios, 724.
Viburnum prunifolium in abortion, 488.
Vicarella on fetal death, 466; on syphilis of nerve-centers, 793.
Vicarious menstruation, 587.
Vicious ankylosis, osteotomy for, 881.
Vierordt on tannalbin, 1143.
Vierviorovsky on syphilis, 1094.
Villiard on orbital cellulitis, 910.
Vinay on puerperal neuritis, 545, 829; on puerperal sepsis, 542.
Vincent on bacteria, 712; on typhoid fever in children, 771.
Vincenzo on pertussis, 774.
Vinci (G.) on eucain, 1118.
Vineberg on anterior kolpotomy, 647; on salicylic acid, 1137; on transvaginal surgery, 644; on vaginofixation, 611.
Vincke on cretinism, 826.
Vinhky on sex, 452.
Vinks (H. H.) on acromegaly, 847.
Virchow on pithecanthropus erectus, 1159; on vaginal cyst, 560.
Virulent cultures of streptococcus, 737.
Visceral complications of erythema exudativum multiforme, 1031.
Visceroptosis, 323.
Vissman on diphtheria-antitoxin, 733.
Visual perceptions, subjective, 929.
Vitali on chloroform in the urine, 1191.
Vitality of spermatozoa, 452.
Vitreous body, diseases of, 929; hemorrhage, 929.
Vitzon on the optic tracts, 930.
Vitzow on regeneration of nerve-cells, 1180.
Vocal bands, vibrations of, 1029; fremitus, 107; resonance, 107.
Vogelius on pneumonia, 112, 698.
Vogl on scarlatina, 766.
Volkmann on acute infectious disease of bone, 884; on carcinoma, 257; on carcinoma of the rectum, 325.
Vollert on eucain, 1119.
Vollmer (H.) on sterilization of catgut, 207.
Volume of blood-corpuscles, 1163.
Voluntary dilatation of the pupil, 813.
Vomiting during anesthesia, 250; hysteric, 811; intractable, 163, 269; neurotic, 811; periodic, 161; pernicious, of pregnancy, 468; tracheal tube for, 163.
Von Barch on the sphygmomanometer, 122.
Von Bardeleben on anatomic nomenclature, 1147.
Von Bechterew on equilibration, 1181.
Von Bergmann on acute osteomyelitis, 370; on brain-surgery, 388; on otitic brain-complications, 989.
Von Düring on multiform erythemata, 1031; on pseudochancre, 1099.
Von Eichstoff on suppurative adenitis, 217.
Von Graefe on dislocation of the lacrimal gland, 910.
Von Hacker on the esophagoscope, 152.
Von Herff on obstetric instrument cases, 451.
Von Hippel on keratitis, 939; on myomia, 898.
Von Jaksch on exophthalmic goiter, 142; on fever, 67.
Von Kahlden on carcinoma of the ovary, 664.
Von Navratil on papilloma of the larynx, 1024.
Von Noorden on the stomach, 1138; on thyroid treatment, 90; on uric-acid concretions, 185.
Von Nussbaum's method, 212.
Von Ruck on tuberculosis, 42.
Von Sicherer on vaccinia, 48.
Von Speyer on twins, 530.
Von Wahl on gastric ulcer, 267.
Von Weismayr on cardiac disease, 128.
Von Woerz on perineal laceration, 520.
Von Wunscheim on nephritis, 191.
Von Ziemmsen on malaria, 1136.
Voorhees on acute yellow atrophy of the liver, 179.
Vorbach on eosinophile cells, 670.
Vos on encephalic syphilis, 949.
Voss on otitic facial paralysis, 968; on otitic sinus-phlebitis, 990.
Vossius on wounds of the eye, 952.
Vulpius on lacrimal obstruction, 910.
Vulva, atresia of, 565; diseases of, 553; elephantiasis of, 558; hematoma of, 544; trachoma of, 554; tumors of, 558.
Vulvar rigidity, 520.
Vulvitis, 554; gonorrheal, 556.
Vulvovaginal anus, 566, 567.
Vulvovaginitis, asaprol in, 802; of children, 379, 554, 797.

WADE on rheumatism, 72.
Wagget on *x*-rays and the larynx, 1021.
Wagon for Pott's disease, 876.
Wahl on obstetric forceps, 533.
Wakley on twins, 530.
Walb on acute otitis media, 966; on otitis media in infancy, 963.
Walcher's position, 512; in forceps operations, 534.
Waldeyer on peritoneal fossæ, 1150.
Walkace on injuries to the digital tendons, 355.
Walker on cocain-poisoning, 1114; on malarial fever, 54; on retinal detachment, 928; on rupture of the quadriceps extensor femoris, 354.
Walko on puerperal tetanus, 541, 841.

Wallenberg on bulbar paralysis, 834.
Wallick on ophthalmia neonatorum, 913.
Walsh on dysentery, 58.
Walsham on dislocation of tendons, 356; on rupture of the bladder, 402.
Walter on symphysiotomy, 535.
Walters on sulfonal exanthemata, 1054; on tuberculosis, 38.
Walthalet on typhoid fever, 26.
Walther on extrauterine pregnancy, 496.
Wandering spleen, splenopexy for, 314.
Warbasse (J. P.) on carcinoma, 628.
Ward on dislocation of the humerus, 375; on syphilis, 1093.
Warden on turbinotomy, 972.
Warman on abortion, 488.
Warren on cervical rib, 338; on duodenal ulcer, 294; on occipitoposterior position, 528.
Warthin on acute tuberculosis, 672.
Washbourn on diphtheria, 761.
Wassilieff on contracted pelvis, 514.
Water in fever, 68.
Waterhouse on hernia in children, 281.
Waterman on bone-diseases, 879.
Wathen on vaginal hysterectomy, 620.
Watkins on anemia, 95; on anterior kolpotomy, 647; on drainage, 652.
Watson (F. S.) on hour-glass contraction of the stomach, 167, 271, 273; on nasal polypi, 1004.
Wawra on tubal pregnancy, 493.
Weaver on summer diarrhea, 784.
Webb on abscess of the lung, 331.
Weber on abdominal section, 650; on atheroma, 147, 683; on exalgin, 1119; on hepatic cirrhosis, 177; on syphilis and lardaceous disease, 1093; on tuberculosis, 36.
Webster on atresia of the vulva and vagina, 565; on ophthalmoplegia, 905.
Weed on cancer of the nose, 1008.
Weeks on cataract, 936; on discission of the capsule, 954; on optic atrophy, 934.
Wegeli on diabetes in children, 780.
Wehling and Krefting on chancroid, 1098.
Weidenfeld on the intercostal muscles, 1178.
Weigert on neuroglia, 1151.
Weight of premature infants, 745.
Weigmann on tumor of the optic nerve, 935.
Weiland on the ophthalmometer, 955; on the retina, 925, 1182; on retinoscopy, 895.
Weinstraud on uric acid, 78.
Weir on ether-anesthesia, 245; on rupture of the urethra, 398; and Foote on hour-glass stomach, 273; on round ulcer of the stomach, 266.
Weisenberg on cervical dystocia, 520.
Weiss on the eye, 892; on hematologic studies, 668; on rheumatism, 74.
Welch on diphtheria, 759.
Wells (S.) on hysteric vomiting of blood, 166; on postoperative intestinal obstruction, 303; on tuberculous peritonitis, 31, 277.
Wells (W. H.) on cervical dystocia, 519; on creolin in labor, 504.
Wende on rhinophyma, 1007; on rhinoscleroma, 1078.
Wendeler on anterior kolpotomy, 610; on extrauterine pregnancy, 497; on syphilis of the cerebral arteries, 682.
Wendling on pregnancy in a double uterus, 476.
Wenzel on digitoxin, 1116; on lactophenin, 93.
Werder on vaginal celiotomy, 609.
Wertheim on dystocia after vaginofixation, 524; on gonorrhea of the uterus, 600; on vaginofixation, 611.
Werziloff on vasomotor nerves, 1167.
Wesener on diphtheria, 762.
Wessinger on bronchitis, 110; on valvular cardiac disease in pregnancy, 470.
West on diabetes mellitus, 87; on pityriasis rubra pilaris, 1079; on pleurisy, 118.
West (J. P.) on enlarged bronchial glands, 789.
Westermark on the ureter, 412.
Westphalen on fetal traumatism, 466.
Wetherla's extractor, 1024.
Wette on exophthalmic goiter, 352.
Whait on leukemia, 102.
Whalen on laryngeal tuberculosis, 1026.
Wharthin on leukocytes, 93.
Wharton (H.) on dislocation of the ulnar nerve, 383; on nevus, 265.
Wheelock on cataract, 937.
Whey-and-cream mixture, 748.
Whipham on acute pemphigus, 1039.
Whiskey in summer diarrhea, 783.
White leg, 541; phlebotomy, 858.
White (A. W.) on superfetation, 530.
White (H.) on acute endocarditis, 124; on diphtheria, 762; on empyema, 119; on pleurisy, 118; on red blood-corpuscles, 1184; on Ritter's disease, 1043.
White (J. W.) on appendicitis, 287; on cicatricial keloid, 264; on fracture of the patella, 365; on a jack-stone in the esophagus removed by *x*-rays, 426.
White (Wood) on corneal ulcer, 940.
Whiteford (C. H.) on Estländer's operation, 343.
Whitehead's operation for piles, 326.
Whitelaw on hemorrhage, 344; on tuberculosis, 34.
Whitelegge on lead-poisoning, 1183.
Whitman on congenital dislocation of the hip, 879; on orthopedic surgery, 873.
Whitton on diabetes mellitus, 83.
Whooping cough, 773; bacteriology of, 697.
Wicherkiewicz on glaucoma, 923; on secondary cataract, 987.
Wickhoff on vesicovaginal fistula, 572.
Wicklein on hepatic abscess, 179.
Widal on gout, 80.
Widmark on cataract, 937; on ophthalmia neonatorum, 913.
Wiederhofer on intestinal tuberculosis in children, 775.
Wiedon on lactation, 510.
Wieland on tuberculous abscess, 877.
Wiener on cholera-vibrios, 724.
Wiesbaden method, 187.
Wiggin (F. H.) on infantile intussusception, 784; on perforation in typhoid fever, 293; on vaginal cyst, 561.
Wightman on empyema in childhood, 334.
Wilcox on typhoid fever, 30.
Wild on ipecacuanha alkaloids, 1123.
Wilkinson on rupture of the uterus, 525.
Willard on club-foot, 886.
Willetts on the perimeter, 955.
Williams on diphtheria, 757; on eneuresis in children, 796; on exophthalmic goiter, 837; on left supraclavicular adenopathy, 307; on nasal polypi, 1004; on pancreatitis, 183; on the photometer, 954; on rheumatism, 73; on Röntgen skiagraphy, 199.
Williams (J. D.) on functional heart-disease in women, 552; on tuberculosis of the cervix uteri, 571; on malignant adenoma of the uterus, 630; on puerperal eclampsia, 514; and Cutler on the pulse in labor, 507.
Williams (W. R.) on carcinoma, 626.
Williamson on glycosuria, 1193.
Willis on puerperal eclampsia, 518.

Wilms on teratomata, 705.
Wilson (C.) on cataract, 938; on chronic disease of the tonsils, 1015; on exophthalmic goiter, 143.
Wilson (J. C.) on gangrene after scarlatina, 766; on perforation in typhoid fever, 27, 294.
Wilson (W. R.) on abdominal pregnancy, 500; on fetal malformation, 468; on multiple gunshot wounds of the intestine, 445.
Winckel on endometritis, 597; on malignant adenoma of the uterus, 630; on supernumerary ovaries, 666.
Winckler on stammering, 1028.
Winkler on goiter, 150.
Winsche on coryza, 1001.
Winter on gastric juice, 1175; on intestinal obstruction, 303; on osmosis and lymph-formation, 1164; on ventral hernia, 656.
Winterberg on acute endocarditis, 123.
Winters on diphtheria, 761; on empyema in children, 790; on hernia after abdominal section, 278.
Wiring of the patella, subcutaneous, 363.
Wirt on joint-disease, 879.
Wissel on gaseous fermentation, 165.
Witch-hazel in the puerperium, 509.
Withington on puerperal tetanus, 541, 841.
Witte on chinosol in labor, 504.
Wittelshöfer on corneal massage, 941.
Witthauer on subphrenic abscess, 173.
Witzel's method, 270.
Woagley on cervical rigidity, 520.
Wölfler on hour-glass stomach, 273.
Wohlmann on rheumatism, 72.
Woldert on hematuria, 56.
Wolf on caries of the ear, 977; on empyema, 698; on pulmonary carcinoma, 120.
Wolfe on epilepsy, 813.
Wolfstein on meningitis, 793.
Woltering on iron, 1125, 1174.
Wolters on syphilis, 1096.
Women, bicycling for, 584; functional heart-disease in, 552; gonorrhea in, 556; hydrocele in, 564; nerve-exhaustion in, 551; renal calculus in, 410, 582; neuralgia in, 552; neurasthenia in, 551; urinary analysis in, 580.
Wood on cataract, 936; on chocolate-amblyopia, 931; on prism-exercise, 903.
Wood (A. C.) on anencephalus, 467; on jack-stone in the esophagus, 426.
Wood (H. C.) on animal extracts, 1104; on anesthetics, 246; on hysteria in children, 795; on marrow-extract, 1107.
Wood (W. C.) on abdominal section, 650.
Woodbridge's method, 29.
Woodruff (E. G.) on coryza, 1001; on precocious menstruation, 586.
Woods on corneal ulcer, 940; on nerve-deafness, 973; on otitic cerebellar abscess, 993.
Woodward on otitic cerebellar abscess, 993; on over-size of the fetus, 531; on phlyctenular conjunctivitis, 916.
Woolen on epistaxis, 1002.
Worcester on acromegaly, 844; on the Dresden mixture, 749; on milk, 511.
Word-blindness, 949.
Wordin on Cesarean section, 536.
Wounds, 416; aseptic, treatment of, 202; of the chest, 328; of the cornea, 941; of the crystalline lens, 952; disinfection of, 201; of the eye, 952; gunshot, 435; of veins, 342.
Woyer on puerperal eclampsia, 515.
Wray on retinal detachment, 928.
Wright on empyema of the antrum, 1008; on hemophilia, 106; on laryngitis sicca, 1021; on mycosis of the throat and nose, 1016; on nasal mucosa, 996; on ozena, 1000; on papilloma of the nasal septum, 1004; on sarcoma of the nose, 1004; on thyroid-feeding in insanity, 870; on urticaria, 1032, 1057; and Mallory on the capsule-bacillus, 715; and Semple on diphtheria, 758; on typhoid-bacilli, 719.
Wroplewski on casein in milk, 510; on pepsin, 163.
Würdeman on infiltration-anesthesia, 240, 908.
Wunderlich on ether-anesthesia, 245.
Wundt on hearing, 1181.
Wunscheim on suppurative nephritis, 701.
Wurtz and Lermoyez on the middle ear, 962.
Wyder on extrauterine pregnancy, 492; on malignant adenoma of the uterus, 630; on uterine fibroid, 616.
Wyeth on how to amputate, 225; method, 233.
Wygodsky on the umbilical cord, 461.
Wylie (G.) on the puerperium, 509.
Wysor on Cesarean section, 536.

x-Rays, 420; and bacteria, 712; and the eye, 953; and insects, 1182; and the larynx, 1021; in medicine, 199; in ophthalmology, 954; in pregnancy, 458; in talipes, 886.
Xanthoma diabeticorum, 1051, 1064; multiplex, 1065.
Xerostoma, 1012.
Xylol for sterilizing catgut, 208.

Yandell on tetanus, 841.
Yeast, brewer's, in diabetes, 86; pathogenic, 711, 725.
Yellow fever, 58, 714; and mosquitoes, 58; organism of, 58.
York on puerperal eclampsia, 514.
Young on dysentery, 59.

Zabludowski on cardiac disease, 136.
Zacharine on steam as a hemostatic, 588.
Zahn on intestinal perforation, 693.
Zahradnicky on myositis, 76.
Zanardi on the alkaloids, 1140.
Zander on the trifacial nerve, 1152.
Zappert on oculomotor palsy, 777; on tuberculous meningitis, 776.
Zaudy on tuberculosis of the alveolar processes, 716.
Zaufal on otitis media in infancy, 963.
Zawadski and Bregman on acute endocarditis, 124.
Zeller on brain-abscess, 993; on ichthyosis uteri, 624; on otitic cerebral abscess, 991.
Zentmayer and Posey on glaucoma, 921.
Ziegelroth on venesection, 96.
Ziegler on ether, 242; on malignant adenoma of the uterus, 630.
Ziem on opening the antrum, 1010.
Zienetz on typhoid fever, 21.
Zimmerman on accommodation, 898; on optic neuritis, 932; on the shadow-test, 954; on sympathetic ophthalmia, 920.
Zinc chlorid in dacryocystitis, 909; -jelly bandage for leg-ulcers, 416; -ointment in burns, 417; oxid in anal pruritus, 327; permanganate in vulvovaginitis, 797; stearate in vulvitis, 554; valerianate in hay fever, 1001.
Zinn on tuberculosis, 43.
Zirm on glaucoma, 922.
Zoege-Manteuffel on wounds of veins, 342.
Zone, diplopsic, 903.
Zoth on the testicle, 1170.
Zuber on pneumonia, 113.
Zuckergussleber, 694.
Zuckerkandl on irritable bladder, 576; on nasal polypi, 1004.
Zuelzer on lithemia, 77.
Zuntz on phloridzin-diabetes, 1171; and Geppert on respiration, 1178.
Zwaardemaker on acoustic railroad signals, 970.
Zweifel on occipitoposterior position, 529; on puerperal eclampsia, 515.

Saunders' "American Year-Book of Medicine and Surgery" (see last page of Catalogue).

Standard Medical and Surgical Works

PUBLISHED BY

W. B. Saunders, 925 Walnut Street, Philadelphia.

MR. SAUNDERS, in presenting to the profession the following list of publications, begs to state that the aim has been to make them worthy of the confidence of medical book-buyers by the high standard of authorship and by the excellence of typography, paper, printing, and binding.

The works indicated in the Index (see next page) with an asterisk (*) are sold by subscription (*not by booksellers*), usually through travelling solicitors, but they can be obtained *direct* from the office of publication (charges of shipment prepaid) by remitting the quoted prices. Full *descriptive circulars* of such works will be sent to any address upon application.

All the other books advertised in this catalogue are commonly for sale by *booksellers* in all parts of the United States; but any book will be sent by the publisher to any address (post-paid) on receipt of the price herein given.

CONTENTS.

Anatomy. PAGE

Haynes, Manual of Anatomy 24
Nancrede, Anatomy and Manual of Dissection . 16
Nancrede, Essentials of Anatomy 26

Bacteriology.

Ball, Essentials of Bacteriology 26
Crookshank, A Text-Book of Bacteriology . . . 13
Frothingham, Laboratory Guide 20
McFarland, Text-Book of Pathogenic Bacteria . 15

Botany.

Bastin, Laboratory Exercises in Botany 20

Chemistry and Physics.

Brockway, Essentials of Physics 26
Wolff, Essentials of Chemistry 26

Children.

*An American Text-Book of Diseases of Children 8
Griffith, Care of the Baby 21
Powell, Essentials of Diseases of Children . . . 26

Clinical Charts, Diet, and Diet Lists.

Hart, Diet in Sickness and in Health 22
Keen, Operation Blank 19
Lainé, Temperature Chart 16
Meigs, Feeding in Early Infancy 14
Starr, Diets for Infants and Children 22
Thomas, Detachable Diet Lists, etc. 22

Diagnosis.

For Sale by Subscription.

AN AMERICAN TEXT-BOOK OF PHYSIOLOGY. Edited by WILLIAM H. HOWELL, PH. D., M. D., Professor of Physiology in the Johns Hopkins University, Baltimore, Md. One handsome octavo volume of 1052 pages, fully illustrated. Prices: Cloth, $6.00 net; Sheep or Half-Morocco, $7.00 net.

This work is the most notable attempt yet made in America to combine in one volume the entire subject of Human Physiology by well-known teachers who have given especial study to that part of the subject upon which they write. The completed work represents the present status of the science of Physiology, particularly from the standpoint of the student of medicine and of the medical practitioner.

American teachers of physiology have not been altogether satisfied with the text-books at their disposal. The defects of most of the older books are that they have not kept pace with the rapid changes in modern physiology, while few if any of the newer books have been uniformly satisfactory in their treatment of all parts of this many-sided science. Indeed, the literature of experimental physiology is so great that it would seem to be almost impossible for any one teacher to keep thoroughly informed on all topics.

The collaboration of several teachers in the preparation of an elementary text-book of physiology is unusual, the almost invariable rule heretofore having been for a single author to write the entire book. One of the advantages to be derived from this collaboration method is that the more limited literature necessary for consultation by each author has enabled him to base his elementary account upon a comprehensive knowledge of the subject assigned to him; another, and perhaps the most important, advantage, is that the student gains the point of view of a number of teachers. In a measure he reaps the same benefit as would be obtained by following courses of instruction under different teachers. The different standpoints assumed, and the differences in emphasis laid upon the various lines of procedure, chemical, physical, and anatomical, should give the student a better insight into the methods of the science as it exists to-day. The work will also be found useful to many medical practitioners who may wish to keep in touch with the development of modern physiology.

The main divisions of the subject-matter are as follows: General Physiology of Muscle and Nerve—Secretion—Chemistry of Digestion and Nutrition—Movements of the Alimentary Canal, Bladder, and Ureter—Blood and Lymph—Circulation—Respiration—Animal Heat—Central Nervous System—Special Senses—Special Muscular Mechanisms—Reproduction—Chemistry of the Animal Body.

AN AMERICAN TEXT-BOOK OF APPLIED THERAPEUTICS. For the Use of Practitioners and Students. Edited by JAMES C. WILSON, M. D., Professor of the Practice of Medicine and of Clinical Medicine in the Jefferson Medical College. One handsome octavo volume of 1326 pages. Illustrated. Prices: Cloth, $7.00 net; Sheep or Half-Morocco, $8.00 net.

The arrangement of this volume has been based, so far as possible, upon modern pathologic doctrines, beginning with the intoxications and following with infections, diseases due to internal parasites, diseases of undetermined origin, and finally the disorders of the several bodily systems—digestive, respiratory, circulatory, renal, nervous, and cutaneous. It was thought proper to include also a consideration of the disorders of pregnancy.

The list of contributors comprises the names of many who have acquired distinction as practitioners and teachers of practice, of clinical medicine, and of the specialties.

The articles, with two exceptions, are the contributions of American writers. Written from the standpoint of the practitioner, the aim of the work is to facilitate the application of knowledge to the prevention, the cure, and the alleviation of disease. The endeavor throughout has been to conform to the title of the book—Applied Therapeutics—to indicate the course of treatment to be pursued at the bedside, rather than to name a list of drugs that have been used at one time or another.

While the scientific superiority and the practical desirability of the metric system of weights and measures is admitted, it has not been deemed best to discard entirely the older system of figures, so that both sets have been given where occasion demanded.

AN AMERICAN TEXT-BOOK OF OBSTETRICS. Edited by RICHARD C. NORRIS, M. D.; Art Editor, ROBERT L. DICKINSON, M. D. One handsome octavo volume of over 1000 pages, with nearly 900 colored and half-tone illustrations. Prices: Cloth, $7.00; Sheep or Half-Morocco, $8.00.

The advent of each successive volume of the *series* of the AMERICAN TEXT-BOOKS has been signalized by the most flattering comment from both the Press and the Profession. The high consideration received by these text-books, and their attainment to an authoritative position in current medical literature, have been matters of deep *international* interest, which finds its fullest expression in the demand for these publications from all parts of the civilized world.

In the preparation of the "AMERICAN TEXT-BOOK OF OBSTETRICS" the editor has called to his aid proficient collaborators whose professional prominence entitles them to recognition, and whose disquisitions exemplify **Practical Obstetrics.** While these writers were each assigned special themes for discussion, the correlation of the subject-matter is, nevertheless, such as ensures logical connection in treatment, the deductions of which thoroughly represent the latest advances in the science, and which elucidate *the best modern methods of procedure.*

The more conspicuous feature of the treatise is its wealth of illustrative matter. The production of the illustrations had been in progress for several years, under the personal supervision of Robert L. Dickinson, M. D., to whose artistic judgment and professional experience is due the **most sumptuously illustrated work of the period.** By means of the photographic art, combined with the skill of the artist and draughtsman, conventional illustration is superseded by rational methods of delineation.

Furthermore, the volume is a revelation as to the possibilities that may be reached in mechanical execution, through the unsparing hand of its publisher.

"At first glance we are overwhelmed by the magnitude of this work in several respects, viz.: First, by the size of the volume, then by the array of eminent teachers in this department who have taken part in its production, then by the profuseness and character of the illustrations, and last, but not least, the conciseness and clearness with which the text is rendered. This is an entirely new composition, embodying the highest knowledge of the art as it stands to-day by authors who occupy the front rank in their specialty, and there are many of them. We cannot turn over these pages without being struck by the superb illustrations which adorn so many of them. We are confident that this most practical work will find instant appreciation by practitioners as well as students."—*New York Medical Times.*

Permit me to say that your American Text-Book of Obstetrics is the most magnificent medical work that I have ever seen. I congratulate you and thank you for this superb work, which alone is sufficient to place you first in the ranks of medical publishers.

With profound respect I am sincerely yours,
ALEX. J. C. SKENE.

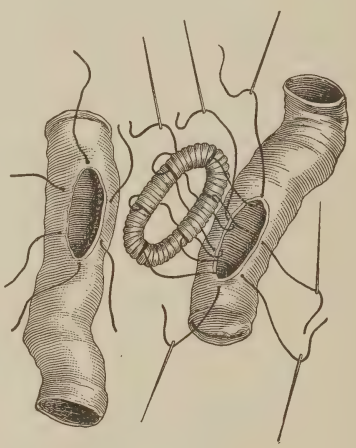
AN AMERICAN TEXT-BOOK OF SURGERY. Edited by WILLIAM W. KEEN, M. D., LL.D., and J. WILLIAM WHITE, M. D., PH. D. Forming one handsome royal-octavo volume of 1250 pages (10×7 inches), with 500 wood-cuts in text, and 37 colored and half-tone plates, many of them engraved from original photographs and drawings furnished by the authors. Prices: Cloth, $7.00; Sheep or Half-Morocco, $8.00 net.



SECOND EDITION, REVISED AND ENLARGED,

With a Section devoted to "The Use of the Röntgen Rays in Surgery."

The want of a text-book which could be used by the practitioner and at the same time be recommended to the medical student has been deeply felt, especially by teachers of surgery; hence, when it was suggested to a number of these that it would be well to unite in preparing a text-book of this description, great unanimity of opinion was found to exist, and the gentlemen below named gladly consented to join in its production.

Especial prominence has been given to Surgical Bacteriology, a feature which is believed to be unique in a surgical text-book in the English language. Asepsis and Antisepsis have received particular attention. The text is brought well up to date in such important branches as cerebral, spinal, intestinal, and pelvic surgery, the most important and newest operations in these departments being described and illustrated.

The text of the entire book has been submitted to all the authors for their mutual criticism and revision—an idea in book-making that is entirely new and original. The book as a whole, therefore, expresses on all the important surgical topics of the day the consensus of opinion of the eminent surgeons who have joined in its preparation.

Specimen Illustration (largely reduced).

One of the most attractive features of the book is its illustrations. Very many of them are original and faithful reproductions of photographs taken directly from patients or from specimens, and the modern improvements in the art of engraving have enabled the publisher to produce illustrations which it is believed are superior to those in any similar work.

AN AMERICAN TEXT-BOOK ON THE THEORY AND PRACTICE OF MEDICINE. By American Teachers. Edited by WILLIAM PEPPER, M. D., LL.D., Provost and Professor of the Theory and Practice of Medicine and of Clinical Medicine in the University of Pennsylvania. Complete in two handsome royal-octavo volumes of about 1000 pages each, with illustrations to elucidate the text wherever necessary. Price per Volume: Cloth, $5.00 net; Sheep or Half-Morocco, $6.00 net.

VOLUME I. CONTAINS:

Hygiene.—Fevers (Ephemeral, Simple Continued, Typhus, Typhoid, Epidemic Cerebro-spinal Meningitis, and Relapsing).—Scarlatina, Measles, Rötheln, Variola, Varioloid, Vaccinia, Varicella, Mumps, Whooping-cough, Anthrax, Hydrophobia, Trichinosis, Actinomycosis, Glanders, and Tetanus.—Tuberculosis, Scrofula, Syphilis, Diphtheria, Erysipelas, Malaria, Cholera, and Yellow Fever.—Nervous, Muscular, and Mental Diseases.

VOLUME II. CONTAINS:

Urine (Chemistry and Microscopy).—Kidney and Lungs.—Air-passages (Larynx and Bronchi) and Pleura.—Pharynx, Œsophagus, Stomach and Intestines (including Intestinal Parasites), Heart, Aorta, Arteries and Veins.—Peritoneum, Liver, and Pancreas.—Diathetic Diseases (Rheumatism, Rheumatoid Arthritis, Gout, Lithæmia, and Diabetes).—Blood and Spleen.—Inflammation, Embolism, Thrombosis, Fever, and Bacteriology.

The articles are not written as though addressed to students in lectures, but are exhaustive descriptions of diseases, with the newest facts as regards Causation, Symptomatology, Diagnosis, Prognosis, and Treatment, including a large number of approved formulæ. The recent advances made in the study of the bacterial origin of various diseases are fully described, as well as the bearing of the knowledge so gained upon prevention and cure. The subjects of Bacteriology as a whole and of Immunity are fully considered in a separate section.

Methods of diagnosis are given the most minute and careful attention, thus enabling the reader to learn the very latest methods of investigation without consulting works specially devoted to the subject.

"We reviewed the first volume of this work, and said: 'It is undoubtedly one of the best text-books on the practice of medicine which we possess.' A consideration of the second and last volume leads us to modify that verdict and to say that the completed work is, in our opinion, the BEST of its kind it has ever been our fortune to see. It is complete, thorough, accurate, and clear. It is well written, well arranged, well printed, well illustrated, and well bound. It is a model of what the modern text-book should be."—*New York Medical Journal.*

"A library upon modern medical art. The work must promote the wider diffusion of sound knowledge."—*American Lancet.*

"A trusty counsellor for the practitioner or senior student, on which he may implicitly rely."—*Edinburgh Medical Journal.*

AN AMERICAN TEXT-BOOK OF THE DISEASES OF CHILDREN. By American Teachers. Edited by LOUIS STARR, M. D., assisted by THOMPSON S. WESTCOTT, M. D. In one handsome royal-8vo volume of 1190 pages, profusely illustrated with wood-cuts, half-tone and colored plates. Prices: Cloth, $7.00 net; Sheep or Half-Morocco, $8.00 net.

The plan of this work embraces a series of original articles written by some sixty well-known pædiatrists, representing collectively the teachings of the most prominent medical schools and colleges of America. The work is intended to be a PRACTICAL book, suitable for constant and handy reference by the practitioner and the advanced student.

One decided innovation is the large number of authors, nearly every article being contributed by a specialist in the line on which he writes. This, while entailing considerable labor upon the editors, has resulted in the publication of a work THOROUGHLY NEW AND ABREAST OF THE TIMES.

Especial attention has been given to the consideration of the latest accepted teaching upon the etiology, symptoms, pathology, diagnosis, and treatment of the disorders of children, with the introduction of many special formulæ and therapeutic procedures.

Special chapters embrace at unusual length the Diseases of the Eye, Ear, Nose and Throat, and the Skin; while the introductory chapters cover fully the important subjects of Diet, Hygiene, Exercise, Bathing, and the Chemistry of Food. Tracheotomy, Intubation, Circumcision, and such minor surgical procedures coming within the province of the medical practitioner, are carefully considered.

AN AMERICAN TEXT-BOOK OF GYNECOLOGY, MEDICAL AND SURGICAL, for the use of Students and Practitioners. Edited by J. M. BALDY, M. D. Forming a handsome royal-octavo volume, with 360 illustrations in text and 37 colored and half-tone plates. Prices: Cloth, $6.00 net; Sheep or Half-Morocco, $7.00 net.

In this volume all anatomical descriptions, excepting those essential to a clear understanding of the text, have been omitted, the illustrations being largely depended upon to elucidate the anatomy of the parts. This work, which is thoroughly practical in its teachings, is intended, as its title implies, to be a working text-book for physicians and students. A clear line of treatment has been laid down in every case, and although no attempt has been made to discuss mooted points, still the most important of these have been noted and explained. The operations recommended are fully illustrated, so that the reader, having a picture of the procedure described in the text under his eye, cannot fail to grasp the idea. All extraneous matter and discussions have been carefully excluded, the attempt being made to allow no unnecessary details to cumber the text. The subject-matter is brought up to date at every point, and the work is as nearly as possible the combined opinions of the ten specialists who figure as the authors.

Specimen Illustration.

The work is well illustrated throughout with wood-cuts, half-tone and colored plates, mostly selected from the authors' private collections.

"The most notable contribution to gynecological literature since 1887, ... and the most complete exponent of gynecology which we have. No subject seems to have been neglected, ... and the gynecologist and surgeon and the general practitioner, who has any desire to practise diseases of women, will find it of practical value. In the matter of illustrations and plates the book surpasses anything we have seen."—*Boston Medical and Surgical Journal.*

A NEW PRONOUNCING DICTIONARY OF MEDICINE, with Phonetic Pronunciation, Accentuation, Etymology, etc. By JOHN M. KEATING, M. D., LL.D., Fellow of the College of Physicians of Philadelphia; Vice-President of the American Pædiatric Society; Ex-President of the Association of Life Insurance Medical Directors; Editor "Cyclopædia of the Diseases of Children," etc.; and HENRY HAMILTON, Author of a "A New Translation of Virgil's Æneid into English Rhyme;" Co-Author of "Saunders' Medical Lexicon," etc.; with the Collaboration of J. CHALMERS DACOSTA, M. D., and FREDERICK A. PACKARD, M. D. With an Appendix, containing Important Tables of Bacilli, Micrococci, Leucomaïnes, Ptomaïnes; Drugs and Materials used in Antiseptic Surgery; Poisons and their Antidotes; Weights and Measures; Thermometric Scales; New Official and Unofficial Drugs, etc. One volume of over 800 pages. Second Revised Edition. Prices: Cloth, $5.00; Sheep or Half-Morocco, $6.00 net; Half-Russia, $6.50 net, with Denison's Patent Ready-Reference Index; without Patent Index, Cloth, $4.00 net; Sheep or Half-Morocco, $5.00 net.

"I am much pleased with Keating's Dictionary, and shall take pleasure in recommending it to my classes."

HENRY M. LYMAN, M. D.,
Professor of Principles and Practice of Medicine, Rush Medical College, Chicago, Ill.

"I am convinced that it will be a very valuable adjunct to my study-table, convenient in size and sufficiently full for ordinary use."

C. A. LINDSLEY, M. D.,
Professor of Theory and Practice of Medicine, Medical Dept. Yale University;
Secretary Connecticut State Board of Health, New Haven, Conn.

MEDICAL DIAGNOSIS. By Dr. OSWALD VIERORDT, Professor of Medicine at the University of Heidelberg. Translated, with additions, from the Second Enlarged German Edition, with the author's permission, by FRANCIS H. STUART, A. M., M. D. Third and Revised Edition. In one handsome royal-octavo volume of 700 pages, 178 fine wood-cuts in text, many of which are in colors. Prices: Cloth, $4.00 net; Sheep or Half-Morocco, $5.00 net; Half-Russia, $5.50 net.

In this work, as in no other hitherto published, are given full and accurate explanations of the phenomena observed at the bedside. It is distinctly a clinical work by a master teacher, characterized by thoroughness, fulness, and accuracy. It is a mine of information upon the points that are so often passed over without explanation. Especial attention has been given to the germ-theory as a factor in the origin of disease.

This valuable work is now published in German, English, Russian, and Italian. The issue of a third American edition within two years indicates the favor with which it has been received by the profession.

"Rarely is a book published with which a reviewer can find so little fault as with the volume before us. All the chapters are full, and leave little to be desired by the reader. Each particular item in the consideration of an organ or apparatus, which is necessary to determine a diagnosis of any disease of that organ, is mentioned; nothing seems forgotten. The chapters on diseases of the circulatory and digestive apparatus and nervous system are especially full and valuable. Notwithstanding a few minor errors in translating, which are of small importance to the accuracy of the rest of the volume, the reviewer would repeat that the book is one of the best—probably, *the best*—which has fallen into his hands. An excellent and comprehensive index of nearly one hundred pages closes the volume."—*University Medical Magazine*, Philadelphia.

PATHOLOGY AND SURGICAL TREATMENT OF TUMORS.

By N. Senn, M. D., Ph. D., LL. D., Professor of Surgery and of Clinical Surgery, Rush Medical College; Professor of Surgery, Chicago Polyclinic; Attending Surgeon to Presbyterian Hospital; Surgeon-in-Chief, St. Joseph's Hospital, Chicago. 710 pages, 515 engravings, including full-page colored plates. Prices: Cloth, $6.00 net; Half-Morocco, $7.00 net.

Books specially devoted to this subject are few, and in our text-books and systems of surgery this part of surgical pathology is usually condensed to a degree incompatible with its scientific and clinical importance. The author spent many years in collecting the material for this work, and has taken great pains to present it in a manner that should prove useful as a text-book for the student, a work of reference for the busy practitioner, and a reliable, safe guide for the surgeon. The more difficult operations are fully described and illustrated. More than *one hundred* of the illustrations are original, while the remainder were selected from books and medical journals not readily accessible to the student and the general practitioner.

"The appearance of such a work is most opportune. . . . In design and execution the work is such as will appeal to every student who appreciates the logical examination of facts and the practical exemplification of well-digested clinical observation."—*Medical Record*, New York.

"The most exhaustive of any recent book in English on this subject. It is well illustrated, and will doubtless remain as the principal monograph on the subject in our language for some years. The book is handsomely illustrated and printed, ... and the author has given a notable and lasting contribution to surgery."—*Journal of American Medical Association*, Chicago.

SURGICAL PATHOLOGY AND THERAPEUTICS.

By John Collins Warren, M. D., LL. D., Professor of Surgery, Medical Department Harvard University; Surgeon to the Massachusetts General Hospital, etc. A handsome octavo volume of 832 pages, with 136 relief and lithographic illustrations, 33 of which are printed in colors, and all of which were drawn by William J. Kaula from original specimens. Prices: Cloth, $6.00 net; Half-Morocco, $7.00 net.

"The volume is for the bedside, the amphitheatre, and the ward. It deals with things not as we see them through the microscope alone, but as the practitioner sees their effect in his patients; not only as they appear in and affect culture-media, but also as they influence the human body; and, following up the demonstrations of the nature of diseases, the author points out their logical treatment" (*New York Medical Journal*). "Indeed, the volume may be termed a modern medical classic, for such is the position to which it has already risen" (*Medical Age*, Detroit), "and is the handsomest specimen of bookmaking * * * that has ever been issued from the American medical press" (*American Journal of the Medical Sciences*, Philadelphia).

Without Exception, the Illustrations are the Best ever Seen in a Work of this Kind.

"A most striking and very excellent feature of this book is its illustrations. Without exception, from the point of accuracy and artistic merit, they are the best ever seen in a work of this kind. * * * Many of those representing microscopic pictures are so perfect in their coloring and detail as almost to give the beholder the impression that he is looking down the barrel of a microscope at a well-mounted section."—*Annals of Surgery*, Philadelphia.

AUTOBIOGRAPHY OF SAMUEL D. GROSS, M. D., Emeritus Professor of Surgery in the Jefferson Medical College of Philadelphia, with Reminiscences of His Times and Contemporaries. Edited by his Sons, SAMUEL W. GROSS, M. D., LL.D., late Professor of Principles of Surgery and of Clinical Surgery in the Jefferson Medical College, and A. HALLER GROSS, A. M., of the Philadelphia Bar. Preceded by a Memoir of Dr. Gross, by the late Austin Flint, M. D., LL.D. In two handsome volumes, each containing over 400 pages, demy 8vo, extra cloth, gilt tops, with fine Frontispiece engraved on steel. Price, $5.00 net.

This autobiography, which was continued by the late eminent surgeon until within three months before his death, contains a full and accurate history of his early struggles, trials, and subsequent successes, told in a singularly interesting and charming manner, and embraces short and graphic pen-portraits of many of the most distinguished men—surgeons, physicians, divines, lawyers, statesmen, scientists, etc.—with whom he was brought in contact in America and in Europe; the whole forming a retrospect of more than three-quarters of a century.

"Dr. Gross . . . was perhaps the most eminent exponent of medical science that America has yet produced. His Autobiography, related as it is with a fulness and completeness seldom to be found in such works, is an interesting and valuable book. He comments on many things, especially, of course, on MEDICAL MEN AND MEDICAL PRACTICE, in a very interesting way. Details of professional life have also much in them that will be new."—*The Spectator*, London, England.

THE PICTORIAL ATLAS OF SKIN DISEASES AND SYPHILITIC AFFECTIONS (American Edition). Translation from the French. Edited by J. J. PRINGLE, M. B., F. R. C. P., Assistant Physician to, and Physician to the department for Diseases of the Skin at, the Middlesex Hospital, London. Photo-lithochromes from the famous models of dermatological and syphilitic cases in the Museum of the Saint-Louis Hospital, Paris, with explanatory wood-cuts and text. In 12 Parts, at $3.00 per Part. Parts 1 to 8 now ready.

"The plates are beautifully executed."—JONATHAN HUTCHINSON, M. D. (London Hospital).

"I strongly recommend this Atlas. The plates are exceedingly well executed, and will be of great value to all studying dermatology."—STEPHEN MACKENZIE, M. D. (London Hospital).

"The plates in this Atlas are remarkably accurate and artistic reproductions of *typical* examples of skin disease. The work will be of great value to the practitioner and student."—WILLIAM ANDERSON, M. D. (St. Thomas Hospital).

"If the succeeding parts of this Atlas are to be similar to Part 1, now before us, we have no hesitation in cordially recommending it to the favorable notice of our readers as one of the finest dermatological atlases with which we are acquainted."—*Glasgow Medical Journal*, Aug., 1895.

"Of all the atlases of skin diseases which have been published in recent years, the present one promises to be of greatest interest and value, especially from the standpoint of the general practitioner."—*American Medico-Surgical Bulletin*, Feb. 22, 1896.

"The introduction of explanatory wood-cuts in the text is a novel and most important feature which greatly furthers the easier understanding of the excellent plates, than which nothing, we venture to say, has been seen better in point of correctness, beauty, and general merit."—*New York Medical Journal*, Feb. 15, 1896.

"An interesting feature of the Atlas is the descriptive text, which is written for each picture by the physician who treated the case or at whose instigation the models have been made. We predict for this truly beautiful work a large circulation in all parts of the medical world where the names *St. Louis* and *Baretta* have preceded it."—*Medical Record*, N. Y., Feb. 1, 1896.

PRACTICAL POINTS IN NURSING. For Nurses in Private Practice. By EMILY A. M. STONEY, Graduate of the Training-School for Nurses, Lawrence, Mass.; Superintendent of the Training-School for Nurses, Carney Hospital, South Boston, Mass. 456 pages, handsomely illustrated with 73 engravings in the text, and 9 colored and half-tone plates. Cloth. Price, $1.75 net.

In this volume the author explains, in popular language and in the shortest possible form, the entire range of *private* nursing as distinguished from *hospital* nursing, and the nurse is instructed how best to meet the various emergencies of medical and surgical cases when distant from medical or surgical aid or when thrown on her own resources.

An especially valuable feature of the work will be found in the directions to the nurse how to *improvise* everything ordinarily needed in the sick-room, where the embarrassment of the nurse, owing to the want of proper appliances, is frequently extreme.

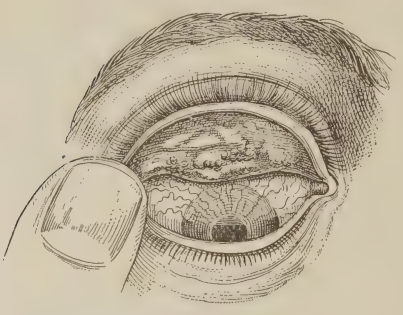
The work has been logically divided into the following sections:

I. The Nurse: her responsibilities, qualifications, equipment, etc.
II. The Sick-Room: its selection, preparation, and management.
III. The Patient: duties of the nurse in medical, surgical, obstetric, and gynecologic cases.
IV. Nursing in Accidents and Emergencies.
V. Nursing in Special Medical Cases.
VI. Nursing of the New-born and Sick Children.
VII. Physiology and Descriptive Anatomy.

The APPENDIX contains much information in compact form that will be found of great value to the nurse, including Rules for Feeding the Sick; Recipes for Invalid Foods and Beverages; Tables of Weights and Measures; Table for Computing the Date of Labor; List of Abbreviations; Dose-List; and a full and complete Glossary of Medical Terms and Nursing Treatment.

"There are few books intended for non-professional readers which can be so cordially endorsed by a medical journal as can this one."—*Therapeutic Gazette*, Aug. 15, 1896.

"This is a well-written, eminently practical volume, which covers the entire range of private nursing as distinguished from hospital nursing, and instructs the nurse how best to meet the various emergencies which may arise and how to prepare everything ordinarily needed in the illness of her patient."—*American Journal of Obstetrics and Diseases of Women and Children*, Aug., 1896.



"It is a work that the physician can place in the hands of his private nurses with the assurance of benefit."—*Ohio Medical Journal*, Aug., 1896.

A TEXT-BOOK OF BACTERIOLOGY, including the **Etiology and Prevention of Infective Diseases** and an account of **Yeasts and Moulds, Hæmatozoa, and Psorosperms.** By EDGAR M. CROOKSHANK, M. B., Professor of Comparative Pathology and Bacteriology, King's College, London. A handsome octavo volume of 700 pages, illustrated with 273 engravings in the text, and 22 original and colored plates. Price, $6.50 net.

This book, though nominally a Fourth Edition of Professor Crookshank's "MANUAL OF BACTERIOLOGY," is practically a new work, the old one having been reconstructed, greatly enlarged, revised throughout, and largely rewritten, forming a text-book for the Bacteriological Laboratory, for Medical Officers of Health, and for Veterinary Inspectors.

DISEASES OF THE EYE. A Hand-Book of Ophthalmic Practice. By G. E. DE SCHWEINITZ, M. D., Professor of Ophthalmology in the Jefferson Medical College, Philadelphia, etc. A handsome royal-octavo volume of 679 pages, with 256 fine illustrations, many of which are original, and 2 chromo-lithographic plates. Prices: Cloth, $4.00 net; Sheep or Half-Morocco, $5.00 net.

The object of this work is to present to the student, and to the practitioner who is beginning work in the fields of ophthalmology, a plain description of the optical defects and diseases of the eye. To this end special attention has been paid to the clinical side of the question; and the method of examination, the symptomatology leading to a diagnosis, and the treatment of the various ocular defects have been brought into prominence.

Specimen Illustration.

SECOND EDITION, REVISED AND GREATLY ENLARGED.

The entire book has been thoroughly revised. In addition to this general revision, special paragraphs on the following new matter have been introduced: Filamentous Keratitis, Blood-staining of the Cornea, Essential Phthisis Bulbi, Foreign Bodies in the Lens, Circinate Retinitis, Symmetrical Changes at the Macula Lutea in Infancy, Hyaline Bodies in the Papilla, Monocular Diplopia, Subconjunctival Injections of Germicides, Infiltration-Anæsthesia, and Sterilization of Collyria. Brief mention of Ophthalmia Nodosa, Electric Ophthalmia, and Angioid Streaks in the Retina also finds place. An Appendix has been added, containing a full description of the method of determining the corneal astigmatism with the ophthalmometer of Javal and Schiötz, and the rotations of the eyes with the tropometer of Stevens. The chapter on Operations has been enlarged and rewritten.

"A clearly written, comprehensive manual. . . . One which we can commend to students as a reliable text-book, written with an evident knowledge of the wants of those entering upon the study of this special branch of medical science."—*British Medical Journal.*

"The work is characterized by a lucidity of expression which leaves the reader in no doubt as to the meaning of the language employed. . . . We know of no work in which these diseases are dealt with more satisfactorily, and indications for treatment more clearly given, and in harmony with the practice of the most advanced ophthalmologists."—*Maritime Medical News.*

"It is hardly too much to say that for the student and practitioner beginning the study of Ophthalmology, it is the best single volume at present published."—*Medical News.*

"The latest and one of the best books on Ophthalmology. The book is thoroughly up to date, and is certainly a work which not only commends itself to the student, but is a ready reference for the busy practitioner."—*International Medical Magazine.*

FEEDING IN EARLY INFANCY. By ARTHUR V. MEIGS, M. D. Bound in limp cloth, flush edges. Price, 25 cents net.

SYNOPSIS: Analyses of Milk—Importance of the Subject of Feeding in Early Infancy—Proportion of Casein and Sugar in Human Milk—Time to Begin Artificial Feeding of Infants—Amount of Food to be Administered at Each Feeding—Intervals between Feedings—Increase in Amount of Food at Different Periods of Infant Development—Unsuitableness of Condensed Milk as a Substitute for Mother's Milk—Objections to Sterilization or "Pasteurization" of Milk—Advances made in the Method of Artificial Feeding of Infants.

A TEXT-BOOK OF HISTOLOGY, DESCRIPTIVE AND PRACTICAL. For the Use of Students. By ARTHUR CLARKSON, M. B., C. M., Edin., formerly Demonstrator of Physiology in the Owen's College, Manchester; late Demonstrator of Physiology in the Yorkshire College, Leeds. Large 8vo, 554 pages, with 22 engravings in the text, and 174 beautifully colored original illustrations. Price, strongly bound in Cloth, $6.00 net.

The purpose of the writer in this work has been to furnish the student of Histology, in one volume, with both the descriptive and the practical part of the science. The first two chapters are devoted to the consideration of the general methods of Histology; subsequently, in each chapter, the structure of the tissue or organ is first systematically described, the student is then taken tutorially over the specimens illustrating it, and, finally, an appendix affords a short note of the methods of preparation.

TEXT-BOOK UPON THE PATHOGENIC BACTERIA. Specially written for Students of Medicine. By JOSEPH MCFARLAND, M. D., Professor of Pathology and Bacteriology in the Medico-Chirurgical College of Philadelphia, etc. 359 pages, finely illustrated. Cloth. Price, $2.50 net.

The book presents a concise account of the technical procedures necessary in the study of Bacteriology. It describes the life-history of pathogenic bacteria, and the pathological lesions following invasions.

The work is intended to be a text-book for the medical student and for the practitioner who has had no recent laboratory training in this department of medical science. The instructions given as to needed apparatus, cultures, stainings, microscopic examinations, etc. are ample for the student's needs, and will afford to the physician much information that will interest and profit him.

"The author has succeeded admirably in presenting the essential details of bacteriological technics, together with a judiciously chosen summary of our present knowledge of pathogenic bacteria. . . . The work, we think, should have a wide circulation among English-speaking students of medicine."—*N. Y. Medical Journal*, April 4, 1896.

A MANUAL OF PHYSIOLOGY, with Practical Exercises. For Students and Practitioners. By G. N. STEWART, M. A., M. D., D. Sc., lately Examiner in Physiology, University of Aberdeen, and of the New Museums, Cambridge University; Professor of Physiology in the Western Reserve University, Cleveland, Ohio. Handsome octavo volume of 800 pages, with 278 illustrations in the text, and 5 colored plates. Price, Cloth, $3.50 net.

"It will make its way by sheer force of merit, and *amply deserves to do so. It is one of the very best English text-books on the subject.*"—*Lancet.*

"Of the many text-books of physiology published, we do not know of one that so nearly comes up to the ideal as does Prof. Stewart's volume."—*British Medical Journal.*

15

WATER AND WATER SUPPLIES. By JOHN C. THRESH, D. Sc., M. B., D. P. H., Lecturer on Public Health, King's College, London; Editor of the "Journal of State Medicine," etc. 12mo, 438 pages, illustrated. Handsomely bound in Cloth, with gold side and back stamps. Price, $2.25 net.

ARCHIVES OF CLINICAL SKIAGRAPHY. By SYDNEY ROWLAND, B. A., Camb., late Scholar of Downing College, Cambridge, and Shuter Scholar of St. Bartholomew's Hospital, London; Special Commissioner to "British Medical Journal" for the Investigation of the Applications of the New Photography to Medicine and Surgery. A series of collotype illustrations, with descriptive text, illustrating the applications of the New Photography to Medicine and Surgery. Price, per Part, $1.00. Parts I. to III. now ready.

The object of this publication is to put on record in permanent form some of the most striking applications of the new photography to the needs of Medicine and Surgery.

The progress of this new art has been so rapid that, although Prof. Röntgen's discovery is only a thing of yesterday, it has already taken its place among the approved and accepted aids to diagnosis.

ESSENTIALS OF ANATOMY AND MANUAL OF PRACTICAL DISSECTION, containing "Hints on Dissection." By CHARLES B. NANCREDE, M. D., Professor of Surgery and Clinical Surgery in the University of Michigan, Ann Arbor; Corresponding Member of the Royal Academy of Medicine, Rome, Italy; late Surgeon Jefferson Medical College, etc. Fourth and revised edition. Post 8vo, over 500 pages, with handsome full-page lithographic plates in colors, and over 200 illustrations. Price: Extra Cloth (or Oilcloth for the dissection-room), $2.00 net.

No pains nor expense has been spared to make this work the most exhaustive yet concise Student's Manual of Anatomy and Dissection ever published, either in America or in Europe. The colored plates are designed to aid the student in dissecting the muscles, arteries, veins, and nerves. The wood-cuts have all been specially drawn and engraved, and an Appendix added containing 60 illustrations representing the structure of the entire human skeleton, the whole being based on the eleventh edition of Gray's *Anatomy*.

A MANUAL OF PRACTICE OF MEDICINE. By A. A. STEVENS, A. M., M. D., Instructor of Physical Diagnosis in the University of Pennsylvania, and Demonstrator of Pathology in the Woman's Medical College of Philadelphia. Specially intended for students preparing for graduation and hospital examinations. Post 8vo, 512 pages. Illustrated. Price, $2.50.

FOURTH EDITION, REVISED AND ENLARGED.

Contributions to the science of medicine have poured in so rapidly during the last quarter of a century that it is well-nigh impossible for the student, with the limited time at his disposal, to master elaborate treatises or to cull from them that knowledge which is absolutely essential. From an extended experience in teaching, the author has been enabled, by classification, to group allied symptoms, and by the elimination of theories and redundant explanations to bring within a comparatively small compass a complete outline of the practice of medicine.

TEMPERATURE CHART. Prepared by D. T. LAINÉ, M. D. Size 8×13½ inches. Price, per pad of 25 charts, 50 cents net.

A conveniently arranged chart for recording Temperature, with columns for daily amounts of Urinary and Fecal Excretions, Food, Remarks, etc. On the back of each chart is given in full the method of Brand in the treatment of Typhoid Fever.

MANUAL OF MATERIA MEDICA AND THERAPEUTICS. By A. A. STEVENS, A. M., M. D., Instructor of Physical Diagnosis in the University of Pennsylvania, and Demonstrator of Pathology in the Woman's Medical College of Philadelphia. 445 pages. Price, Cloth, $2.25.

SECOND EDITION, REVISED.

This wholly new volume, which is based on the last edition of the *Pharmacopœia*, comprehends the following sections: Physiological Action of Drugs; Drugs; Remedial Measures other than Drugs; Applied Therapeutics; Incompatibility in Prescriptions; Table of Doses; Index of Drugs; and Index of Diseases; the treatment being elucidated by more than two hundred formulæ.

NOTES ON THE NEWER REMEDIES: their Therapeutic Applications and Modes of Administration. By DAVID CERNA, M.D., PH.D., Demonstrator of and Lecturer on Experimental Therapeutics in the University of Pennsylvania. Post 8vo, 253 pages. Price, $1.25.

SECOND EDITION, RE-WRITTEN AND GREATLY ENLARGED.

The work takes up in alphabetical order all the newer remedies, giving their physical properties, solubility, therapeutic applications, administration, and chemical formula.

SAUNDERS' POCKET MEDICAL FORMULARY. By WILLIAM M. POWELL, M. D., Attending Physician to the Mercer House for Invalid Women at Atlantic City. Containing 1750 Formulæ, selected from several hundred of the best-known authorities. Forming a handsome and convenient pocket companion of nearly 300 printed pages, with blank leaves for additions; with an Appendix containing Posological Table, Formulæ and Doses for Hypodermic Medication, Poisons and their Antidotes, Diameters of the Female Pelvis and Fœtal Head, Obstetrical Table, Diet List for Various Diseases, Materials and Drugs used in Antiseptic Surgery, Treatment of Asphyxia from Drowning, Surgical Remembrancer, Tables of Incompatibles, Eruptive Fevers, Weights and Measures, etc. Third edition, revised and greatly enlarged. Handsomely bound in morocco, with side index, wallet, and flap. Price, $1.75 net.

"This little book, that can be conveniently carried in the pocket, contains an immense amount of material. It is very useful, and as the name of the author of each prescription is given is unusually reliable."—*New York Medical Record.*

SAUNDERS' POCKET MEDICAL LEXICON; or, Dictionary of Terms and Words used in Medicine and Surgery. By JOHN M. KEATING, M. D., Editor of "Cyclopædia of Diseases of Children," etc.; Author of the "New Pronouncing Dictionary of Medicine," and HENRY HAMILTON, Author of "A New Translation of Virgil's Æneid into English Verse;" Co-Author of a "New Pronouncing Dictionary of Medicine." A new and revised edition. 32mo, 282 pages. Prices: Cloth, 75 cents; Leather Tucks, $1.00.

"Remarkably accurate in terminology, accentuation, and definition."—*Journal of American Medical Association.*

DISEASES OF WOMEN. By HENRY J. GARRIGUES, A. M., M. D., Professor of Obstetrics in the New York Post-Graduate Medical School and Hospital; Gynæcologist to St. Mark's Hospital, and to the German Dispensary, etc., New York City. One octavo volume of nearly 700 pages, illustrated by 300 wood-cuts and colored plates. Prices: Cloth, $4.00 net; Sheep, $5.00 net.

A PRACTICAL work on gynæcology for the use of students and practitioners, written in a terse and concise manner. The importance of a thorough knowledge of the anatomy of the female pelvic organs has been fully recognized by the author, and considerable space has been devoted to the subject. The chapters on Operations and on Treatment are thoroughly modern, and are based upon the large hospital and private practice of the author. The text is elucidated by a large number of illustrations and colored plates, many of them being original, and forming a complete atlas for studying *embryology* and the *anatomy* of the *female genitalia*, besides exemplifying, whenever needed, morbid conditions, instruments, apparatus, and operations.

EXCERPT OF CONTENTS.

Development of the Female Genitals.—Anatomy of the Female Pelvic Organs.—Physiology.—Puberty.—Menstruation and Ovulation.—Copulation.—Fecundation.—The Climacteric.—Etiology in General.—Examinations in General.—Treatment in General.—Abnormal Menstruation and Metrorrhagia.—Leucorrhea.—Diseases of the Vulva.—Diseases of the Perineum.—Diseases of the Vagina.—Diseases of the Uterus.—Diseases of the Fallopian Tubes.—Diseases of the Ovaries.—Diseases of the Pelvis.—Sterility.

The reception accorded to this work has been most flattering. In the short period which has elapsed since its issue, it has been adopted and recommended as a text-book by more than 60 of the Medical Schools and Universities of the United States and Canada.

"One of the best text-books for students and practitioners which has been published in the English language; it is condensed, clear, and comprehensive. The profound learning and great clinical experience of the distinguished author find expression in this book in a most attractive and instructive form. Young practitioners, to whom experienced consultants may not be available, will find in this book invaluable counsel and help."

THAD. A. REAMY, M. D., LL.D.,
Professor of Clinical Gynecology, Medical College of Ohio; Gynecologist to the Good Samaritan and to the Cincinnati Hospitals.

ESSENTIALS OF PHYSICAL DIAGNOSIS OF THE THORAX. By ARTHUR M. CORWIN, A. M., M. D., Demonstrator of Physical Diagnosis in the Rush Medical College, Chicago; Attending Physician to the Central Free Dispensary, Department of Rhinology, Laryngology, and Diseases of the Chest. 200 pages. Illustrated. Cloth, flexible covers. Price, $1.25 net.

This book was originally published for the use of students, but its rapid absorption by the practitioner made it appear that a wider field had been reached. In this edition the author has added to his revision of the text a section setting forth the signs found in each of the diseases of the chest, thereby increasing its value to the general practitioner for post-graduate study.

"It is excellent. The student who shall use it as his guide to the careful study of physical exploration upon normal and abnormal subjects can scarcely fail to acquire a good working knowledge of the subject."—*Philadelphia Polyclinic.*

SYLLABUS OF OBSTETRICAL LECTURES in the Medical Department, University of Pennsylvania. By RICHARD C. NORRIS, A. M., M. D., Demonstrator of Obstetrics in the University of Pennsylvania. Third edition, thoroughly revised and enlarged. Crown 8vo. Price, Cloth, interleaved for notes, $2.00 net.

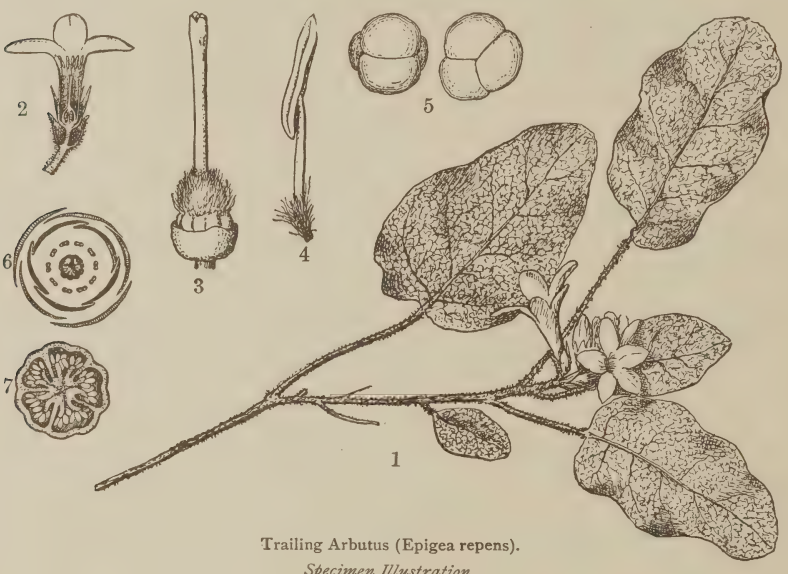
"This work is so far superior to others on the same subject that we take pleasure in calling attention briefly to its excellent features. It covers the subject thoroughly, and will prove invaluable both to the student and the practitioner. The author has introduced a number of valuable hints which would only occur to one who was himself an experienced teacher of obstetrics. The subject-matter is clear, forcible, and modern. We are especially pleased with the portion devoted to the practical duties of the accoucheur, care of the child, etc. The paragraphs on antiseptics are admirable; there is no doubtful tone in the directions given. No details are regarded as unimportant; no minor matters omitted. We venture to say that even the old practitioner will find useful hints in this direction which he cannot afford to despise."—*Medical Record.*

A SYLLABUS OF GYNECOLOGY, arranged in conformity with "An American Text-Book of Gynecology." By J. W. LONG, M. D., Professor of Diseases of Women and Children, Medical College of Virginia, etc. Price, Cloth (interleaved), $1.00 net.

Based upon the teaching and methods laid down in the larger work, this will not only be useful as a supplementary volume, but to those who do not already possess the Text-Book it will also have an independent value as an aid to the practitioner in gynecological work, and to the student as a guide in the lecture-room, as the subject is presented in a manner systematic, succinct, and practical.

A SYLLABUS OF LECTURES ON THE PRACTICE OF SURGERY, arranged in conformity with "An American Text-Book of Surgery." By NICHOLAS SENN, M. D., PH. D., Professor of Surgery in Rush Medical College, Chicago, and in the Chicago Polyclinic. Price, $2.00.

This excellent work of its eminent author, himself one of the contributors to "An American Text-Book of Surgery," will prove of exceptional value to the advanced student who has adopted that work as his text-book. It is not only the syllabus of an unrivalled course of surgical practice, but it is also an epitome of, or supplement to the larger work.



AN OPERATION BLANK, with Lists of Instruments, etc. required in Various Operations. Prepared by W. W. KEEN, M. D., LL.D., Professor of Principles of Surgery in the Jefferson Medical College, Philadelphia. Price per pad, containing Blanks for fifty operations, 50 cents net.

SECOND EDITION, REVISED FORM.

A convenient blank (suitable for all operations), giving complete instructions regarding necessary preparation of patient, etc., with a full list of dressings and medicines to be employed. On the back of each blank is a list of instruments used—viz. general instruments, etc., required for all operations; and special instruments for surgery of the brain and spine, mouth and throat, abdomen, rectum, male and female genito-urinary organs, the bones, etc. The whole forming a neat pad, arranged for hanging on the wall of a surgeon's office or in the hospital operating-room.

LABORATORY EXERCISES IN BOTANY. By EDSON S. BASTIN, M. A., Professor of Materia Medica and Botany in the Philadelphia College of Pharmacy. Octavo volume of 536 pages, with 87 plates. Price, Cloth, $2.50.

This work is intended for the beginner and the advanced student, and it fully covers the structure of flowering plants, roots, ordinary stems, rhizomes, tubers, bulbs, leaves, flowers, fruits, and seeds. Particular attention is given to the gross and microscopical structure of plants, and to those used in medicine. The illustrations fully elucidate the text, and the complete index facilitates reference.

Trailing Arbutus (Epigea repens).
Specimen Illustration.

LABORATORY GUIDE FOR THE BACTERIOLOGIST. By LANGDON FROTHINGHAM, M. D. V., Assistant in Bacteriology and Veterinary Science, Sheffield Scientific School, Yale University. Illustrated. Price, Cloth, 75 cents.

The technical methods involved in bacteria-culture, methods of staining, and microscopical study are fully described and arranged as simply and concisely as possible. The book is especially intended for use in laboratory work.

OBSTETRIC ACCIDENTS, EMERGENCIES, AND OPERATIONS. By L. CH. BOISLINIERE, M. D., late Emeritus Professor of Obstetrics in the St. Louis Medical College. 381 pages, handsomely illustrated. Price, $2.00 net.

"For the use of the practitioner who, when away from home, has not the opportunity of consulting a library or of calling a friend in consultation. He then, being thrown upon his own resources, will find this book of benefit in guiding and assisting him in emergencies."

HOW TO EXAMINE FOR LIFE INSURANCE. By JOHN M. KEATING, M. D., Fellow of the College of Physicians and Surgeons of Philadelphia; Vice-President of the American Pædiatric Society; Ex-President of the Association of Life Insurance Medical Directors. Royal 8vo, 211 pages, with two large half-tone illustrations, and a plate prepared by Dr. McClellan from special dissections; also, numerous cuts to elucidate the text. Price, in Cloth, $2.00 net.

"This is by far the most useful book which has yet appeared on insurance examination, a subject of growing interest and importance. Not the least valuable portion of the volume is Part II., which consists of instructions issued to their examining physicians by twenty-four representative companies of this country. As the proofs of these instructions were corrected by the directors of the companies, they form the latest instructions obtainable. If for these alone the book should be at the right hand of every physician interested in this special branch of medical science."—*The Medical News*, Philadelphia.

THE CARE OF THE BABY. By J. P. CROZER GRIFFITH, M. D., Clinical Professor of Diseases of Children, University of Pennsylvania; Physician to the Children's Hospital, Philadelphia, etc. 392 pages, with 67 illustrations in the text, and 5 plates. 12mo. Price, $1.50.

A reliable guide not only for mothers, but also for medical students and practitioners whose opportunities for observing children have been limited.

"The whole book is characterized by rare good sense, and is evidently written by a master hand. It can be read with benefit not only by mothers, but by medical students and by any practitioners who have not had large opportunities for observing children."—*American Journal of Obstetrics*, July, 1895.

"The best book for the use of the young mother with which we are acquainted. . . . There are very few general practitioners who could not read the book through with advantage."—*Archives of Pediatrics*, Aug., 1895.

"No better book of its kind has come under our notice for some time. Although intended primarily for mothers and nurses, it will well repay perusal by medical students."—*Birmingham Medical Review*, Oct., 1895.

"This is one of the best works of its kind that has been presented to the people for many a day."—*Maryland Medical Journal*, Aug. 13, 1895.

NURSING: ITS PRINCIPLES AND PRACTICE. By ISABEL ADAMS HAMPTON, Graduate of the New York Training School for Nurses attached to Bellevue Hospital; Superintendent of Nurses, and Principal of the Training School for Nurses, Johns Hopkins Hospital, Baltimore, Md.; late Superintendent of Nurses, Illinois Training School for Nurses, Chicago, Ill. In one very handsome 12mo volume of 484 pages, profusely illustrated. Price, Cloth, $2.00 net.

This original work on the important subject of nursing is at once comprehensive and systematic. It is written in a clear, accurate, and readable style, suitable alike to the student and the lay reader. Such a work has long been a desideratum with those intrusted with the management of hospitals and the instruction of nurses in training-schools. It is also of especial value to the graduate nurse who desires to acquire a practical working knowledge of the care of the sick and the hygiene of the sick-room.

NURSE'S DICTIONARY of Medical Terms and Nursing Treatment, containing Definitions of the Principal Medical and Nursing Terms and Abbreviations; of the Instruments, Drugs, Diseases, Accidents, Treatments, Physiological Names, Operations, Foods, Appliances, etc. encountered in the ward or in the sick-room. Compiled for the use of nurses. By HONNOR MORTEN, Author of "How to Become a Nurse," "Sketches of Hospital Life," etc. 16mo, 140 pages. Price, Cloth, $1.00.

This little volume is intended merely as a small reference-book which can be consulted at the bedside or in the ward. It gives sufficient explanation to the nurse to enable her to comprehend a case until she has leisure to look up larger and fuller works on the subject.

DIET IN SICKNESS AND IN HEALTH. By MRS. ERNEST HART, formerly Student of the Faculty of Medicine of Paris and of the London School of Medicine for Women; with an INTRODUCTION by Sir Henry Thompson, F. R. C. S., M. D., London. 220 pages; illustrated. Price, Cloth, $1.50.

Useful to those who have to nurse, feed, and prescribe for the sick. . . . In each case the accepted causation of the disease and the reasons for the special diet prescribed are briefly described. Medical men will find the dietaries and recipes practically useful, and likely to save them trouble in directing the dietetic treatment of patients.

"We recommend it cordially to the attention of all practitioners; . . . . both to them and to their patients it may be of the greatest service."—*Medical Journal*, New York.

DIETS FOR INFANTS AND CHILDREN IN HEALTH AND IN DISEASE. By LOUIS STARR, M. D., Editor of "An American Text-Book of the Diseases of Children." 230 blanks (pocket-book size), perforated and neatly bound in flexible morocco. Price, $1.25 net.

The first series of blanks are prepared for the first seven months of infant life; each blank indicates the ingredients, but not the *quantities*, of the food, the latter directions being left for the physician. After the seventh month, modifications being less necessary, the diet lists are printed in full. *Formulæ* for the preparation of diluents and foods are appended.

DIET LISTS AND SICK-ROOM DIETARY. By JEROME B. THOMAS, M. D., Visiting Physician to the Home for Friendless Women and Children and to the Newsboys' Home; Assistant Visiting Physician to the Kings County Hospital; Assistant Bacteriologist, Brooklyn Health Department. Price, $1.50. Send for sample sheet.

There is here offered, in portable form, as an efficient aid to the better practice of Therapeutics, a collection of detachable Diet Lists and a Sick-room Dietary. It meets a want, for the busy practitioner has but little time to write out *Systems of Diet* appropriate to his patients, or to describe the preparation of their food. Compiled from the most modern works on dietetics, the Dietary offers a variety of easily-digested foods.

"A convenience that will be appreciated by the physician."—*Medical Journal*, New York.

"The work is an excellent one, and ought to be welcomed by physician, patient, and nurse alike."—*Indian Lancet*, Calcutta.

Practical, Exhaustive, Authoritative.

SAUNDERS'

NEW AID SERIES OF MANUALS.

FOR

STUDENTS AND PRACTITIONERS.

Mr. Saunders is pleased to announce the successful issue of several volumes of his **NEW AID SERIES OF MANUALS, which have received the most flattering commendations from Students and Practitioners and the Press.** As publisher of the Standard Series of Question Compends, and through intimate relations with leading members of the medical profession, Mr. Saunders has been enabled to study progressively the essential *desiderata* in practical "self-helps" for students and physicians.

This study has manifested that, while the published "Question Compends" earn the highest appreciation of students, whom they serve in reviewing their studies preparatory to examination, there is special need of thoroughly reliable handbooks on the leading branches of Medicine and Surgery, each subject being compactly and authoritatively written, and exhaustive in detail, without the introduction of *cases* and foreign subject-matter which so largely expand ordinary text-books.

The Saunders Aid Series will not merely be condensations from present literature, but will be ably written by well-known authors and practitioners, most of them being teachers in representative American Colleges. This *new series*, therefore, will form an admirable collection of advanced lectures, which will be invaluable aids to students in reading and in comprehending the contents of "recommended" works.

Each Manual will further be distinguished by the beauty of the *new* type; by the quality of the paper and printing; by the copious use of illustrations; by the attractive binding in cloth; **and by the extremely low price at which they will be sold.**

Saunders' New Aid Series of Manuals.

VOLUMES PUBLISHED.

PHYSIOLOGY, by JOSEPH HOWARD RAYMOND, A. M., M. D., Professor of Physiology and Hygiene and Lecturer on Gynecology in the Long Island College Hospital; Director of Physiology in the Hoagland Laboratory; formerly Lecturer on Physiology and Hygiene in the Brooklyn Normal School for Physical Education; Ex-Vice-President of the American Public Health Association; Ex-Health Commissioner, City of Brooklyn, etc. Illustrated. $1.25 net.

SURGERY, General and Operative, by JOHN CHALMERS DACOSTA, M. D., Demonstrator of Surgery, Jefferson Medical College, Philadelphia; Chief Assistant Surgeon, Jefferson Medical College Hospital; Surgical Registrar, Philadelphia Hospital, etc. 188 illustrations and 13 plates. (Double number.) $2.50 net.

DOSE-BOOK AND MANUAL OF PRESCRIPTION-WRITING, by E. Q. THORNTON, M. D., Demonstrator of Therapeutics, Jefferson Medical College, Philadelphia. Illustrated. Price, cloth, $1.25 net.

Illustrated. $1.50 net.

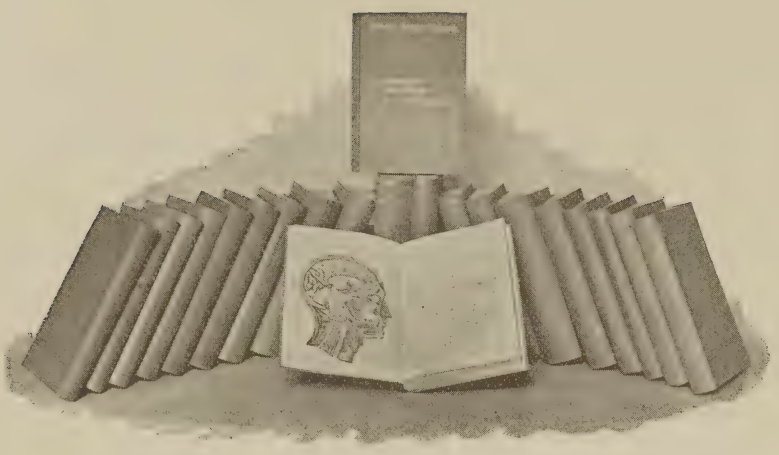
SYPHILIS AND THE VENEREAL DISEASES, by JAMES NEVINS HYDE, M. D., Professor of Skin and Venereal Diseases, and FRANK H. MONTGOMERY, M. D., Lecturer on Dermatology and Genito-Urinary Diseases, in Rush Medical College, Chicago. Profusely Illustrated. (Double number.) $2.50 net.

PRACTICE OF MEDICINE, by GEORGE ROE LOCKWOOD, M. D., Professor of Practice in the Woman's Medical College of the New York Infirmary; Instructor of Physical Diagnosis of the Medical Department of Columbia College; Attending Physician to the Colored Hospital; Pathologist to the French Hospital; Member of the New York Academy of Medicine, of the Pathological Society, of the Clinical Society, etc. Illustrated. (Double number.) $2.50 net.

MANUAL OF ANATOMY, by IRVING S. HAYNES, M. D., Adjunct Professor of Anatomy and Demonstrator of Anatomy, Medical Department of the New York University, etc. Beautifully Illustrated. (Double number.) Price, $2.50 net.

MANUAL OF OBSTETRICS, by W. A. NEWMAN DORLAND, M. D., Asst. Demonstrator of Obstetrics, University of Pennsylvania; Chief of Gynecological Dispensary, Pennsylvania Hospital; Member of Philadelphia Obstetrical Society, etc. Profusely illustrated. (Double number.) Price, $2.50 net.



VOLUMES IN PREPARATION.

DISEASES OF WOMEN, by J. BLAND SUTTON, F. R. C. S., Assistant Surgeon to the Middlesex Hospital, London, and ARTHUR EDWARD GILES, M. D. Handsomely illustrated. (Double number.)

NOSE AND THROAT, by D. BRADEN KYLE, M. D., Chief Laryngologist of the St. Agnes Hospital, Philadelphia; Bacteriologist of the Orthopædic Hospital and Infirmary for Nervous Diseases; Instructor in Clinical Microscopy and Assistant Demonstrator of Pathology in the Jefferson Medical College, etc.

NERVOUS DISEASES, by CHARLES W. BURR, M. D., Clinical Professor of Nervous Diseases, Medico-Chirurgical College, Philadelphia; Pathologist to the Orthopædic Hospital and Infirmary for Nervous Diseases; Visiting Physician to the St. Joseph Hospital, etc.

*** There will be published in the same series, at close intervals, carefully-prepared works on the subjects of Children, Gynecology, Hygiene, etc., by prominent specialists.

SAUNDERS' QUESTION COMPENDS.

Arranged in Question and Answer Form.

THE LATEST, CHEAPEST, AND BEST ILLUSTRATED SERIES OF COMPENDS EVER ISSUED.

Now the Standard Authorities in Medical Literature

WITH

Students and Practitioners in every City of the United States and Canada.

THE REASON WHY

They are the advance guard of "Student's Helps"—that DO HELP; they are the leaders in their special line, *well and authoritatively written by able men, who, as teachers in the large colleges, know exactly what is wanted by a student preparing for his examinations.* The judgment exercised in the selection of authors is fully demonstrated by their professional elevation. Chosen from the ranks of Demonstrators, Quiz-masters, and Assistants, most of them have become Professors and Lecturers in their respective colleges.

Each book is of convenient size (5 × 7 inches), containing on an average 250 pages, profusely illustrated, and elegantly printed in clear, readable type, on fine paper.

The entire series, numbering twenty-three volumes, has been kept thoroughly revised and enlarged when necessary, many of them being in their fourth and fifth editions.

TO SUM UP.

Although there are numerous other Quizzes, Manuals, Aids, etc. in the market, none of them approach the "Blue Series of Question Compends;" and the claim is made for the following points of excellence:

1. Professional distinction and reputation of authors.
2. Conciseness, clearness, and soundness of treatment.
3. Size of type and quality of paper and binding.

*** **Any of these Compends will be mailed on receipt of price** **(see over for List).**

Saunders' Question-Compend Series.

Price, Cloth, $1.00 per copy, except when otherwise noted.

1. **ESSENTIALS OF PHYSIOLOGY.** 3d edition. Illustrated. Revised and enlarged. By H. A. HARE, M. D. (Price, $1.00 net.)

2. **ESSENTIALS OF SURGERY.** 5th edition, with an Appendix on Antiseptic Surgery. 90 illustrations. By EDWARD MARTIN, M. D.

3. **ESSENTIALS OF ANATOMY.** 5th edition, with an Appendix. 180 illustrations. By CHARLES B. NANCREDE, M. D.

4. **ESSENTIALS OF MEDICAL CHEMISTRY, ORGANIC AND INORGANIC.** 4th edition, revised, with an Appendix. By LAWRENCE WOLFF, M. D.

5. **ESSENTIALS OF OBSTETRICS.** 3d edition, revised and enlarged. 75 illustrations. By W. EASTERLY ASHTON, M. D.

6. **ESSENTIALS OF PATHOLOGY AND MORBID ANATOMY.** 6th thousand. 46 illustrations. By C. E. ARMAND SEMPLE, M. D.

7. **ESSENTIALS OF MATERIA MEDICA, THERAPEUTICS, AND PRESCRIPTION-WRITING.** 4th edition. By HENRY MORRIS, M. D.

8, 9. **ESSENTIALS OF PRACTICE OF MEDICINE.** By HENRY MORRIS, M. D. An Appendix on URINE EXAMINATION. Illustrated. By LAWRENCE WOLFF, M. D. 3d edition, enlarged by some 300 Essential Formulæ, selected from eminent authorities, by WM. M. POWELL, M. D. (Double number, price $2.00.)

10. **ESSENTIALS OF GYNÆCOLOGY.** 3d edition, revised. With 62 illustrations. By EDWIN B. CRAGIN, M. D.

11. **ESSENTIALS OF DISEASES OF THE SKIN.** 3d edition, revised and enlarged. 71 letter-press cuts and 15 half-tone illustrations. By HENRY W. STELWAGON, M. D. (Price, $1.00 net.)

12. **ESSENTIALS OF MINOR SURGERY, BANDAGING, AND VENEREAL DISEASES.** 2d edition, revised and enlarged. 78 illustrations. By EDWARD MARTIN, M. D.

13. **ESSENTIALS OF LEGAL MEDICINE, TOXICOLOGY, AND HYGIENE.** 130 illustrations. By C. E. ARMAND SEMPLE, M. D.

14. **ESSENTIALS OF DISEASES OF THE EYE, NOSE, AND THROAT.** 124 illustrations. 2d edition, revised. By EDWARD JACKSON, M. D., and E. BALDWIN GLEASON, M. D.

15. **ESSENTIALS OF DISEASES OF CHILDREN.** 2d edition. By WILLIAM M. POWELL, M. D.

16. **ESSENTIALS OF EXAMINATION OF URINE.** Colored "VOGEL SCALE," and numerous illustrations. By LAWRENCE WOLFF, M. D. (Price, 75 cents.)

17. **ESSENTIALS OF DIAGNOSIS.** By S. SOLIS-COHEN, M. D., and A. A. ESHNER, M. D. 55 illustrations, some in colors. (Price, $1.50 net.)

18. **ESSENTIALS OF PRACTICE OF PHARMACY.** By L. E. SAYRE. 2d edition, revised and enlarged.

20. **ESSENTIALS OF BACTERIOLOGY.** 2d edition. 81 illustrations. By M. V. BALL, M. D.

21. **ESSENTIALS OF NERVOUS DISEASES AND INSANITY.** 48 illustrations. 2d edition, revised. By JOHN C. SHAW, M. D.

22. **ESSENTIALS OF MEDICAL PHYSICS.** 155 illustrations. 2d edition, revised. By FRED J. BROCKWAY, M. D. (Price, $1.00 net.)

23. **ESSENTIALS OF MEDICAL ELECTRICITY.** 65 illustrations. By DAVID D. STEWART, M. D., and EDWARD S. LAWRANCE, M. D.

24. **ESSENTIALS OF DISEASES OF THE EAR.** By E. B. GLEASON, M. D. 89 illustrations.

JUST PUBLISHED.

A TEXT-BOOK OF MATERIA MEDICA, THERAPEUTICS, AND PHARMACOLOGY. By GEORGE F. BUTLER, PH. G., M. D., Professor of Materia Medica and of Clinical Medicine in the College of Physicians and Surgeons, Chicago; Professor of Materia Medica and Therapeutics, Northwestern University, Woman's Medical School, etc. 8vo, 858 pages. Illustrated. Prices: Cloth, $4.00 net; Sheep or Half-Morocco, $5.00 net.

A clear, concise, and practical text-book, adapted for permanent reference no less than for the requirements of the class-room. The arrangement (embodying the synthetic classification of drugs based upon therapeutic affinities) is believed to be at once the most philosophical and rational, as well as that best calculated to engage the interest of those to whom the academic study of the subject is wont to offer no little perplexity.

Special attention has been given to the Pharmaceutical section, which is exceptionally lucid and complete.

LECTURES ON RENAL AND URINARY DISEASES. By ROBERT SAUNDBY, M. D. Edin., Fellow of the Royal College of Physicians, London, and of the Royal Medico-Chirurgical Society; Physician to the General Hospital; Consulting Physician to the Eye Hospital and to the Hospital for Diseases of Women; Professor of Medicine in Mason College, Birmingham, etc. 8vo, 434 pages, with numerous illustrations and 4 colored plates. Price, Cloth, $2.50 net.

In these Lectures, which are a re-issue in one volume of the author's well-known works on *Bright's Disease* and *Diabetes*, there is given, within a modest compass, a review of the present state of knowledge of these important affections, with such additions and suggestions as have resulted from the author's thirteen years' clinical and pathological study of the subjects. The lectures have been carefully revised and much new matter added to them. There has also been added a section dealing with "Miscellaneous Affections of the Kidney," making the book more complete as a work of reference.

ELEMENTARY BANDAGING AND SURGICAL DRESSING, with Directions concerning the Immediate Treatment of Cases of Emergency. For the use of Dressers and Nurses. By WALTER PYE, F. R. C. S., late Surgeon to St. Mary's Hospital, London. Small 12mo, with over 80 illustrations. Cloth, flexible covers. Price, 75 cents net.

This little book is chiefly a condensation of those portions of Pye's "Surgical Handicraft" which deal with bandaging, splinting, etc., and of those which treat of the management in the first instance of cases of emergency. Within its own limits, however, the book is complete, and it is hoped that it will prove extremely useful to students when they begin their work in the wards and casualty rooms, and useful also to surgical nurses and dressers.

"The directions are clear and the illustrations are good."—*London Lancet.*

"The author writes well, the diagrams are clear, and the book itself is small and portable, although the paper and type are good."—*British Medical Journal.*

"One of the most useful little works for dressers and nurses. The author truly says that it is 'a very little book,' but it is large in usefulness."—*Chemist and Druggist.*

ANOMALIES

AND

CURIOSITIES OF MEDICINE.

BY

GEORGE M. GOULD, M. D.,

AND

WALTER L. PYLE, M. D.

Several years of exhaustive research have been spent by the authors in the great medical libraries of the United States and Europe in collecting the material for this work. **Medical literature of all ages and all languages** has been carefully searched, as a glance at the Bibliographic Index will show. The facts, which will be of **extreme value to the author and lecturer,** have been arranged and annotated, and full reference footnotes given, indicating whence they have been obtained.

In view of the persistent and dominant interest in the anomalous and curious, a **thorough and systematic collection** of this kind (the first of which the authors have knowledge) must have its own peculiar sphere of usefulness.

As a complete and authoritative **Book of Reference** it will be of value not only to members of the medical profession, but to all persons interested in general scientific, sociologic, and medico-legal topics; in fact, the general interest of the subject and the dearth of any complete work upon it make this volume **one of the most important literary innovations of the day.**

An especially valuable feature of the book consists of the **Indexing.** Besides a complete and comprehensive **General Index,** containing numerous cross-references to the subjects discussed, and the names of the authors of the more important reports, there is a convenient **Bibliographic Index** and a **Table of Contents.**

The plan has been adopted of printing the **topical headings in bold-face type,** the reader being thereby enabled to tell at a glance the subject-matter of any particular paragraph or page.

Illustrations have been freely employed throughout the work, there being 165 relief cuts and 130 half-tones in the text, and 12 colored and half-tone full-page plates—a total of over 320 separate figures.

The careful rendering of the text and references, the wealth of illustrations, the mechanical skill represented in the typography, the printing, and the binding, combine to make this book one of the most attractive medical publications ever issued.

Handsome Imperial Octavo Volume of 968 Pages.

PRICES: Cloth, $6.00 net; Half Morocco, $7.00 net.

IN PREPARATION FOR EARLY PUBLICATION.

AN AMERICAN TEXT-BOOK OF GENITO-URINARY AND SKIN DISEASES.

Edited by L. Bolton Bangs, M. D., Late Professor of Genito-Urinary and Venereal Diseases, New York Post-Graduate Medical School and Hospital, and William A. Hardaway, M. D., Professor of Diseases of the Skin, Missouri Medical College.

AN AMERICAN TEXT-BOOK OF DISEASES OF THE EYE, EAR, NOSE, AND THROAT.

Edited by G. E. de Schweinitz, M. D., Professor of Ophthalmology in the Jefferson Medical College, and B. Alexander Randall, M. D., Professor of Diseases of the Ear in the University of Pennsylvania and in the Philadelphia Polyclinic.

MACDONALD'S SURGICAL DIAGNOSIS AND TREATMENT.

Surgical Diagnosis and Treatment. By J. W. Macdonald, M. D., Graduate of Medicine of the University of Edinburgh; Licentiate of the Royal College of Surgeons, Edinburgh; Professor of the Practice of Surgery and of Clinical Surgery, Minneapolis College of Physicians and Surgeons.

ANDERS' THEORY AND PRACTICE OF MEDICINE.

A Text-Book of the Theory and Practice of Medicine. By James M. Anders, M. D., Ph. D., LL.D., Professor of the Theory and Practice of Medicine and of Clinical Medicine, Medico-Chirurgical College, Philadelphia.

SENN'S GENITO-URINARY TUBERCULOSIS.

Tuberculosis of the Genito-Urinary Apparatus, Male and Female. By Nicholas Senn, M. D., Ph. D., LL.D., Professor of the Practice of Surgery and of Clinical Surgery, Rush Medical College, Chicago.

PENROSE'S GYNECOLOGY.

A Text-Book of Gynecology. By Charles B. Penrose, M. D., Professor of Gynecology, University of Pennsylvania.

HIRST'S OBSTETRICS.

A Text-Book of Obstetrics. By Barton Cooke Hirst, M. D., Professor of Obstetrics, University of Pennsylvania.

MOORE'S ORTHOPEDIC SURGERY.

A Manual of Orthopedic Surgery. By James E. Moore, M. D., Professor of Orthopedics and Adjunct Professor of Clinical Surgery, University of Minnesota, College of Medicine and Surgery.

HEISLER'S EMBRYOLOGY.

A Text-Book of Embryology. By John C. Heisler, M. D., Prosector to the Professor of Anatomy, Medical Department of the University of Pennsylvania.

New Volume in Saunders' Aid Series.

SUTTON AND GILES' DISEASES OF WOMEN.

Diseases of Women. By J. Bland Sutton, F. R. C. S., Assistant Surgeon to the Middlesex Hospital, and Surgeon to the Chelsea Hospital for Women, London; and Arthur E. Giles, M. D., B. Sc. Lond., F. R. C. S. Edin., Assistant Surgeon to the Chelsea Hospital for Women, London. Handsomely Illustrated.

NOW READY—VOLUMES FOR 1896 AND 1897.

SAUNDERS'

American Year-Book of Medicine and Surgery

COLLECTED AND ARRANGED BY EMINENT AMERICAN SPECIALISTS AND TEACHERS,

UNDER THE EDITORIAL CHARGE OF

GEORGE M. GOULD, M. D.

The knowledge gained is equivalent to a post-graduate course.

Uniform in size with the "American Text-Book" Series.

NOTWITHSTANDING the rapid multiplication of medical and surgical works, still these publications fail to meet fully the requirements of the *general physician*, inasmuch as he feels the need of something more than mere text-books of well-known principles of medical science. Mr. Saunders has long been impressed with this fact, which is confirmed by the unanimity of expression from the profession at large, as indicated by advices from his large corps of canvassers.

This deficiency would best be met by current journalistic literature, but most practitioners have scant access to this almost unlimited source of information, and the busy practiser has but little time to search out in periodicals the many interesting cases, whose study would doubtless be of inestimable value in his practice. Therefore, a work which places before the physician in convenient form *an epitomization of this literature by persons competent to pronounce upon*

The Value of a Discovery or of a Method of Treatment

cannot but command his highest appreciation. It is this critical and judicial function that will be assumed by the Editorial staff of the "American Year-Book of Medicine and Surgery."

It is the special purpose of the Editor, whose experience peculiarly qualifies him for the preparation of this work, not only to review the contributions to American journals, but also the methods and discoveries reported in the leading medical journals of Europe, thus enlarging the survey and making the work characteristically **international.** These reviews will not simply be a series of undigested abstracts indiscriminately run together, nor will they be retrospective of "news" *one or two years old*, but the treatment presented will be *synthetic* and *dogmatic*, and will include **only what is new.** Moreover, through expert condensation by experienced writers, these discussions will be

Comprised in a Single Volume of about 1200 Pages.

The work will be replete with **original** and **selected** illustrations skilfully reproduced, for the most part, in Mr. Saunders' own studios established for the purpose, thus ensuring accuracy in delineation, affording efficient aids to a right comprehension of the text, and adding to the attractiveness of the volume.

Prices: Cloth, $6.50 net; Half Morocco, $7.50 net.
